**ABSTRACT**

Six clinical *Staphylococcus aureus* strains isolated from different clinical samples. Isolates ASIA1 and ASIA2 isolated from urine samples of urinary tract infected patients; ASIA3 isolated from swab samples of burn abscess patients at Assiut University hospital as well as ASIA4, ASIA5 and ASIA6 obtained from blood samples of different cancer patients at South Egypt Cancer Institute. All isolates showed varied abilities to produce halo zones of hydrolysis with different diameters on blood agar, heated plasma agar, casein agar and skim milk agar plates along with different clot lyses percent. *Staphylococcus aureus* ASIA3, ASIA4 and ASIA6 produced 4.83, 5.98 and 2.08 U/mL of staphylokinase on tryptone soy broth reduced to 1.95, 2.08 and 1.70 U/mL on casein hydrolysate yeast extract broth, respectively. On the other hand, *Staphylococcus aureus* ASIA1, ASIA2 and ASIA5 gave 2.20, 2.93 and 3.65 U/mL on CYEB compared to 2.10, 1.88 and 3.41 U/mL on TSB as production medium. The staphylokinase yielded from the hyperactive producer *Staphylococcus aureus* ASIA4 was increased for 7.64-fold (from 2.08 U/mL to 15.88 U/mL) on the optimized fermentation medium composed of 5.0 g sucrose as carbon source, 10.0 g soy bean as nitrogen source, 5.0 g NaCl, K2HPO4 5.0 g and pH 7.0 that inoculated with isolate ASIA4 and incubated for 24 h at 35°C. Moreover, Staphylokinase activity reached its peak at the optimal enzymatic reaction conditions which were reaction time 25 min, casein as substrate, reaction pH 8.0, reaction temperature 40°C. In addition, it retained 100% of its activity at temperature ranged between 15 and 45°C and pH ranged from pH 6.0 to 9.0 EDTA inhibited the enzyme activity by 3.0% to 32.2% with increasing its values from 30.0 to 90.0 mM. MgCl2 at a concentration of 30 mM increased the enzyme activity by 4% and then slightly decreased at higher concentrations but NaCl was potent staphylokinase activator at concentrations lower than 90 mM.

**Keywords:** Staphylokinase; *Staphylococcus aureus*; Thrombicolytic agents; Optimization; Characterization

**INTRODUCTION**

Thrombotic disorders are a major cause of death and morbidity worldwide. Thrombosis like vascular blockage, pulmonary embolism, peripheral occlusive disease, deep vein thrombosis, stroke and acute myocardial infarction are commonly known as heart attack due to blood clot [1]. Currently, many blood clot-dissolving agents are either approved for clinical use or under clinical examination in patients with acute myocardial infarction, such as staphylokinase, streptokinase, urokinase, tissue plasminogen activator (t-PA) and plasminogen activator recombinant (rPSU-PA; recombinant prourokinase) [2]. There is a lot of research available that includes screen and characterization of microorganisms that produce enzymes with high thrombolytic activity since most of the commonly used medicines have complications such as bleeding, allergies, expensive, re-blockage [3]. Hence, thrombolytic therapy needs additional effective thrombolytic drugs, which afford fast improved efficacy and fibrin specificity of fibrin-dissolving agents with minimal side effects like minimal bleeding risk and re-occlusion at low cost [4]. Bacterial staphylokinase (E.C. 3.4.99.22) is an extra cellular protein composed of 136 amino acids synthesized through the
late exponential growth phase of lysogenic Staphylococcus aureus [5]. It has ideal fibrin specific plasminogen activator and clot specificity than t-PA by converting a precursor plasminogen to plasin which results in dissolving a blood clot along with destroying the natural components of the blood clotting system, leading to life-threatening as well as death consequence [6]. After activation, plasmin cleaves variable substrates such as fibrin and extracellular matrix proteins and activates proteases and other growth factors then fibrinolysis including staphylokinase and plasin are implicated in a variety of physiological and pathophysiological procedures for example wound curing, irritation, cell migration, embryogenesis, cancer development, metastasis, angiogenesis and atherosclerosis [3,7]. The main reason for selecting staphylokinase enzyme in the present study is finding relatively inexpensive thrombolytic drug and alternative cure against cardiac blood clot when compared to other commercial thrombolytic agents. Therefore, the present study has been undertaken to isolate the local strains of S. aureus from clinical samples, screened them for the production of staphylokinase (SAK), testing their thrombolytic activity in vitro, optimization the fermentation process parameters and enzymatic assay conditions as well as characterization of the obtained enzyme.

MATERIALS AND METHODS

Media and reagents

Nutrient agar (g/L; peptone 5.0, sodium chloride 5.0, beef extract 3.0 and agar 20.0); mannitol salt agar (MSA g/L; peptone10.0, beef extract 1.0, sodium chloride 75.0, mannitol 10.0, phenol red 0.025, agar 20.0 and pH 7.4 ± 0.2); trypentine broth (g/L; trypentine 10.0, beef extract 3.0, glucose 5.0, blood 5% and pH 7.2 ± 0.2); methyl red-voges proskauer broth (MR-VP, g/L; trypentine 10.0, glucose 5.0, K2HPO4 5.0, and pH 6.9 ± 0.2), trypentine soya broth (TSB, g/L; pancreatic digest of casein 17.0, soya bean 3.0, glucose 2.5, NaCl 5.0, K2HPO4 2.5 and pH 7.3 ± 0.2) and casein yeast extract broth (CYE, g/L; casein acid hydrolysate 30.0, yeast extract 4.0, dextrose 2.0, K2HPO4 0.50 and pH 7.2 ± 0.2) media were used. Methyl red reagent (0.1 g MR in 300 mL 95% ethanol and 200 mL H2O), Voges- proskauer reagent (Barrit B 40% of potassium hydroxide and Barrit A 5% α-naphthol in absolute ethanol), trichloroacetic acid (10 g TCA in 100 mL H2O and casein solution (500 mg casein in 100 mL of 0.1 M phosphate buffer) were prepared.

Collection of clinical samples

Staphylococcus aureus strains were isolated from different clinical samples from urine samples of urinary tract infected and swab samples of burn abscess patients at Assiut University hospital as well as from the blood samples of different multiple myeloma patients at South Egypt Cancer Institute.

Bacterial isolation and sub-culturing

All samples were primarily inoculated into nutrient broth, incubated at 37°C for 24 h and serial dilution was spread on nutrient agar, mannitol salt agar and blood agar media, incubated at 37°C for 24 h and select expected S. aureus [8]. The individual colonies were observed, checked for their purity by microscopy. Isolates were maintained on nutrient agar supplemented with 5% blood at 4°C until optimization and characterization studies.

Phenotypic identification of isolates

Isolates were characterized by Phenotypic characters including Gram stain, motility, and haemolytic activity. Moreover, antibiotics resistant, catalase (to examine the ability of strains to detoxify hydrogen peroxide via secretion of catalase enzyme which act on conversion of H2O2 to H2O and O2 by adds 2 drops of H2O2 on a touch of organism colony), carbohydrate fermentation, coagulase (0.5 mL of plasma mixed with 0.5 mL of broth culture from tested organism), indole (by inoculated tryptone broth medium with tested organisms, incubated at 37°C for 48 h and then Kovac's reagent was added to the test tube and positive result appear as red layer at the top of medium) and methyl red tests (MRVP by inoculated MR-VP broth medium with each tested isolate, incubated at 37°C for 48h and then adding MR reagent to test tube and positive result appear as red layer on the top of medium). Identification of isolates was confirmed by VITECK-2 tests.

Screening of staphylokinase producers

Bacteria are main sources for thrombolytic drugs. Therefore in the current work searching for staphylokinase was performed on the six S. aureus isolates by using different methods heated plasma agar assay, radial caseinolytic assay (includes casein agar and skim milk agar assays) and in-vitro clot lyses at different concentrations of enzyme preparation 10, 20 and 30 μL. After inoculation of SAK producing S. aureus on heated plasma agar plate, each clear fibrinolytic halo after each treatment was observed around the well after overnight incubation at 37°C. In casein hydrolysis assay, the hydrolysis of casein was identified by a zone of clearance around the growth of colonies on casein agar plates and skim milk agar plates after incubation at 37°C for 24 h. In vitro thrombolysis study was assayed according to the formula: % clot lyses=(Weight of the lysis clot/Weight of clot before lysis) × 100 at 37°C after 90 min of incubating clots with enzyme preparations as previously reported.

Production and quantitative assay of staphylokinase

Staphylokinase productivity by a selected S. aureus strains was evaluated using two different media namely modified trypentine soy broth (TSB) and casein hydrolysate yeast extract (CYE) at pH 7.0 and 37°C for 24 hour at 120 rpm. After fermentation period, the activity of staphylokinase (U/mL) was determined by using casein digestion method. One unit of caseinolytic activity was determined as the amount of enzyme releasing 1 μmole of tyrosine equivalent/min.
Optimization

With the aim of studying the outcome of pH on staphylokinase production, the fermentation process was performed at various pHs ranged from 4.0 to 9.0 as well as the impact of different incubation temperatures (25°C to 40°C) on enzyme productivity was assessed. For optimizing nutritional requirements that supported the highest staphylococcal yields, the carbon source in the TSB medium, glucose, was replaced by various six carbon sources including fructose, sucrose, maltose, sorbitol, lactose and starch individually at 5 g/L. The nitrogen source of TSB (mixture of 17 g pancreatic digest of casein and 3 g soya bean) was substituted with peptone, soya bean, casein, beef extract, yeast extract, corn steep liquor and NH₄NO₃ individually as sole nitrogen source at 10 g/L. Effect of the amino acids supplementations (alanine glycine, histidine, cysteine and lysine) at a concentration of 2 g/L) in addition to soya bean was assessed. NaCl of TSB medium was replaced by CaCl₂, MgCl₂, FeSO₄, KNO₃, ZnSO₄ and CuSO₄ to evaluate the influence of these metal sources individually on the production process of staphylokinase. All the experiments were carried out in duplicates.

Characterization of staphylokinase

This step was performed in order to maintain the maximum enzymatic activity through optimization of reaction time of assay (at 5 to 30 min), pH of assay and pH stability of enzyme (at different pH 5.0, 6.0, 7.0, 8.0 and 9.0), impact of temperature on activity and stability of enzyme (at 15°C to 60°C), substrate concentrations (at 0.45 to 3.6 mM) and the impact of different metal sources MgCl₂ and NaCl as well as EDTA at a concentrations of 10, 30, 50, 70 and 90 mM, individually on enzyme activity were estimated. Growth characterization of S. aureus was estimated.

RESULTS

Isolation, morphological and biochemical characterization of S. aureus

Six of S. aureus strains were isolated, S. aureus ASIA1 and S. aureus ASIA2 were obtained from urine samples of urinary tract infected patients and S. aureus ASIA3 was isolated from swab samples of burn abscess patients at Assuit University hospital but S. aureus ASIA4, S. aureus ASIA5 and S. aureus ASIA6 were isolated from blood samples of different cancer patients at South Egypt Cancer Institute. In line with our results different author reported the distribution of S. aureus in the clinical human samples. For instant reported that from urine samples of UTI suspected patients screened 119 isolates (33.52%) showed grow out of which S. aureus were 22 isolates (48.88%), in which 8 strains were MRSA (36.36%) and 14 strains MSSA (63.63%). He stated the prevalence of S. aureus from urinary tract infection (UTIs) and gastroenteritis patients aged from 8 to 18 years. On the other hand, reported that cancer patients are susceptible to staphylococcal infection owing to a number of reasons comprising prolonged hospitalization and operating time, intravascular catheterization, compromise immunity, malignancy, chemotherapy, radiotherapy and antibiotic therapy. Moreover isolated 468 S. aureus isolates from cancer patients among them 283 were MRSA and isolated 41 clinical S. aureus out of them 73.2% were from El-Demerdash hospital and 26.8% from Ain Shams Specialized hospital.

All isolates were Gram positive cocci in clusters or singly, in mannitol salt agar medium all S. aureus isolates appeared round, smooth, raised, mucoid, glistening and golden yellow surrounded with large yellow zone due to fermentation of mannitol and production of acid (Figure 1). The isolates were grown on blood agar medium with large, round, creamy greyish white colonies with smooth translucent area surrounding the colonies as a result of β-haemolysis production. All isolates were positive for coagulase test (coagulase positive Staphylococci, but negative for indole test. They were catalase and methyl red test positive. In accordance with our data, previously studies reported that S. aureus isolates grown on blood agar with β-hemolysis activity and on mannitol salt agar medium, which considered a selective and differential medium for S. aureus turned its color from red to yellow as a result of mannitol fermentation and acid production and they are positive for catalase, coagulase and MR-VP tests but negative for indole test [5]. Also, Shah and Panchal, stated that S. aureus isolates are snowy, creamy to gold color and as Gram positive cocci with β-haemolysis on blood agar and proteolysis on casein agar plates [3].

Figure 1: Gram positive cocci of S. aureus ASIA1 to ASIA6 isolates.

Screening of clinical S. aureus strains for staphylokinase activity using different methods

Different methods including hemolysis on blood agar (blood hemolysis activity), heated plasma agar (Plasminolytic activity), casein agar and skim milk agar plates (casienolytic activity) along with determining thrombolysis activity (% of clot lysis) were performed to evaluate staphylokinase activity in six isolates of S. aureus at different concentrations 10, 20 and 30 µL. Results revealed that all of the six strains showed promising ability to produce hydrolysis halo zones and clot lysis on blood agar, plasma agar, casein agar and skim milk agar plates around each culture filtrate of each bacterial isolate at each concentration. Results also showed that these local isolates differ in their abilities in staphylokinase production. The highest diameter of halo zones estimated to be (1.80, 2.20 and 2.60 cm), (2.0, 2.8 and 3.6 cm), (1.3, 1.80 and 2.5 cm) and (0.8, 1.5 and 2.0 cm) were detected in S. aureus ASIA4 with blood agar, heated plasma agar, casein agar
and skim milk agar plates at an enzyme concentrations of 10, 20 and 30 μL, respectively. Moreover, in vitro thrombolysis study showed that the SAK producing S. aureus ASIA4 isolate showed the highest present 30%, 69% and 86% clot lysed by S. aureus ASIA3 (24%, 51% and 74% clot lysed) and S. aureus ASIA5 (19%, 40% and 67% clot lysed) after treatment with 10, 20 and 30 μL of each enzyme preparation, respectively. Our results are in agreement with the reported that 10 μL of the staphylokinase enzyme can partially lyse the clot, but in between 40 to 60 μL complete lysis of the clot was observed [7]. Thrombolytic agents, staphylokinase, can positively impact the outcome of these deadly diseases such as myocardial infarction, cerebrovascular thrombosis, and venous thromboembolism but thrombolysis has major deficiencies including high healing dosages, inadequate fibrin specificity and bleeding problems [6]. Our results are in consonance with other studies achieved by Devriese and Kerckhovea, they detected staphylokinase production by S. aureus isolated from human infections based on the clear zones of hydrolysis on plasma agar medium after an overnight incubation at 37°C. Moreover, recorded zones of hydrolysis around the well containing culture filtrate of 19 urinary tract infected S. aureus isolates; ranged between 25 and 36 mm, stated the ability of S. aureus isolates to produce different levels of staphylokinase and producing zone of hydrolysis on plasma agar and reported that out of 50 S. aureus isolates, 10 isolates hydrolyzed casein and produce radial caseinolysis zone ranged from 6 to 25 mm [2,4,5].

Quantitative evaluation of staphylokinase activity in clinical S. aureus strains using different fermentation media

Each S. aureus isolate was inoculated into two different fermentation media, tryptone soy broth and casein hydrolysate yeast extract broth, incubated for 24 h at 37°C, after fermentation period, fermented media were centrifuged at 10,000 rpm and the free cells supernatants were collected for detection of staphylokinase enzyme (U/mL). Results indicated that the impact of tryptone soy broth medium and casein hydrolysate yeast extract (CYEB) on staphylokinase production was dependent on the producing strain. Tryptone soy broth supported the highest staphylokinase production in S. aureus ASIA3, ASIA4 and ASIA6 which estimated to be 4.83, 5.98 and 2.08 U/mL but these yields were reduced to 1.95, 2.08 and 1.70 U/mL, respectively on casein hydrolysate yeast extract broth. Conversely, CYEB medium was the best production medium for staphylokinase from S. aureus ASIA1, ASIA2 and ASIA5 which gave 2.20, 2.93 and 3.65 U/mL compared to 2.10, 1.88 and 3.41 U/mL on TSB. Then, S. aureus ASIA4 (5.98 U/mL) was chosen as the hyperactive staphylokinase producer for optimization and characterization studies on TSB medium. In line with our results Devriese and Kerckhovea, reported that tryptone soya medium was promising medium for more than 91% of 55 S. aureus strains of human origin compared to 18% with nutrient agar for staphylokinase productivity.

Optimization the production process parameters of staphylokinase by S. aureus ASIA4

The influence of pH of medium on staphylokinase production by S. aureus ASIA4 was performed at varied pH values; the enzyme productivity was increased by increasing the pH value from 4.0 to 7.0 and then decreased. The enzyme yields were increased by 1.44, 2.89, 5.93, 3.48 and 2.14 fold after increasing the pH of medium from 4.0 to 5.0, 6.0, 7.0, 8.0 and 9.0, respectively, then pH 7.0 was the optimal pH for S. aureus ASIA4 staphylokinase production. In accordance with the present work reported that pH 7.0 is the best for maximizing growth and enzyme productivity and then decrease at lower or higher pH. Furthermore, S. aureus ASIA4 was able to grow and produce staphylokinase at a wide range of temperature, it produced 3.38, 4.95, 8.91 and 7.98 U/mL at incubation temperature of 25, 30, 35 and 37°C, respectively and then sharply decreased to 4.13 U/mL at 40°C, hence optimum temperature was 35°C. He reported that variation of pHs and incubation temperatures had a large impact on the uptake of the nutrients by the cells; hence, this phenomenon makes it mandatory to optimize the pH of the medium and incubation temperature [4]. Staphylokinase (SAK) production by Staphyloccocus sp. was greatly affected at highly acidic and alkaline pH but the maximum SAK activity was observed at pH 6.5 at 30°C and decrease with further increase in the incubation temperature [4].

Different sugars including glucose, starch, sucrose, sorbitol and lactose were evaluated as sole carbon source for staphylokinase production. The best yield of enzyme production (10.85 U/mL) from S. aureus ASIA4 was achieved with sucrose followed by Maltose (9.70 U/mL) while the lowest yield of enzyme was obtained with lactose, sorbitol and starch (5.35, 2.43 and 4.90 U/mL, respectively) as sole carbon source compared to 8.91 U/mL with glucose. He reported that among diverse sugars such as fructose, galactose, lactose, maltose, glucose and sucrose; only glucose supported the maximum productivity of staphylokinase. Moreover, basal nitrogen source of TSB medium (3.0 g soya bean+10.0 g pancreatic digest of casein) by the organic nitrogen sources comprise beef extract, casein, peptone, corn steep liquor and yeast extract, individually the enzyme productivity increased from 10.80 to 11.16, 12.63, 14.22 and 15.79 U/mL with the organic nitrogen sources peptone, casein, yeast extract and soy bean, respectively while the inorganic nitrogen NH4NO3 increased staphylokinase productivity to 11.02 U/mL. On the other hand the productivity was decreased by 38.98% and 52.77% with beef extract and corn step liquor, respectively, then soy bean was the best nitrogen source.

Moreover, all amino acids suplementations include alanine, glycine, histidine and lysine had negative effects on staphylokinase production. They decreased enzyme production by 76.21%, 87.25%, 75.13% and 69.83%, respectively but they increased the growth by 66.39%, 95.97%, 62.93% and 83.44%; which may be due to the imbalance in the C/N ratio occurred after adding each of these amino acids to the soy bean as well as the lower productivity of the enzyme can be attributed to the fact that the amino acids encouraged and prolonged the growth phase at the expense of the production phase as previously stated. He suggested yeast extract as the best nitrogen to achieve the highest yield of growth and staphylokinase enzyme. Also Deepa et al., suggested that yeast extract acts as a major nitrogen source for the production of SAK and shows maximum activity at a concentration of 2.65% (w/v) [4]. In the case of replacing the
Characterization of staphylokinase enzyme

Temperature and pH of enzymatic reaction among the most important factors that impacted both enzyme activity and stability, the enzyme retained 100% of its activity at temperature ranged between 15°C to 45°C and then lost 40%, 56% and 81% of its activity at 50, 55 and 60°C, respectively but the maximum enzyme activity was achieved at 40°C. Nguyen and Quyen reported that the staphylokinase from S. aureus QT08 was active in a broad temperature range of 20°C to 45°C and had optimum temperature of 30°C to 37°C along with it was stable at a temperature range from 15°C to 37°C but it was inactive at high temperature (70°C). Activity of staphylokinase compared to the control (pH 7.0 with 100% relative activity) was significantly affected at the acidic pH and lost 68.4% of its activity at pH 5.0 but it was slightly affected at alkaline pH and lost 4.8% of its relative activity at pH 9.0. The staphylokinase activity reached its peak at pH 8.0. However, the enzyme was stable and retained 100% of its activity at pH ranged between pH 6.0 to pH 9.0. Interestingly, Nguyen and Quyen recommended pH 8.5 in Tris-HCl buffer and pH 7.5 in phosphate buffer for the best SAK activity with pH stability at a pH range of 4.0 to 9.0. The optimum reaction time for staphylokinase enzyme with casein as substrate was estimated to be 25 min but at lower reaction time the enzyme activity was loosed 74.8%, 67.6%, 44.20% and 20.20% after reaction time equal to 5, 10, 15 and 20 min as well as among varied concentrations ranged between 0.45 to 3.6 mM; 0.45, 0.90 and 1.80 mM increased the enzymatic activity by 6%, 15% and 7%, respectively and then decreased at higher concentrations of casein. Our results are in agreement they reported that the optimum enzymatic reaction time for staphylokinase from Staphylococcus was 20 to 30 min [7].
