We propose a theory of quark and lepton mass and mixing with non-universal $Z'$ couplings based on a 5d Standard Model with quarks and leptons transforming as triplets under a new gauged $SO(3)$ isospin. In the 4d effective theory, the $SO(3)$ isospin is broken to $U(1)'$, through a $S^1/(\mathbb{Z}_2 \times \mathbb{Z}_2')$ orbifold, then subsequently dynamically broken, resulting in a massive $Z'$. Quarks and leptons in the 5d bulk appear as massless modes, with zero Yukawa couplings to the Higgs on the brane, and zero couplings to $Z'$, at leading order, due to the $U(1)'$ symmetry. However, after the $U(1)'$ breaking, both Yukawa couplings and non-universal $Z'$ couplings are generated by heavy Kaluza-Klein exchanges. Hierarchical quark and lepton masses result from a hierarchy of 5d Dirac fermion masses. Neutrino mass and mixing arises from a novel type Ib seesaw mechanism, mediated by Kaluza-Klein Dirac neutrinos. The non-universal $Z'$ couplings may contribute to semi-leptonic $B$ decay ratios which violate $\mu - e$ universality. In this model such couplings are related to the corresponding quark and lepton effective Yukawa couplings.
1 Introduction

The flavour puzzle in the Standard Model (SM) is an indication that it is not complete. Of the almost thirty parameters of the SM, most of them arise from unspecified Higgs Yukawa couplings. This provides a motivation for studying theories of flavour beyond the SM, in which the origin of Yukawa couplings is considered from a different perspective.

One interesting approach that was proposed some time ago is based on the idea that the usual Higgs Yukawa couplings with the three families of chiral fermions are forbidden by a discrete $Z_2$ symmetry, which is subsequently broken by some new scalar field $\langle \phi \rangle$, allowing the Higgs Yukawa couplings to arise effectively from mixing with a vector-like fourth family [1]. If the $Z_2$ symmetry is replaced by a gauged $U(1)'$ symmetry, under which the SM fermions are neutral, but the Higgs doublets are charged, thereby forbidding Yukawa couplings but allowing mixing with the charged vector-like fourth family, then after $U(1)'$ symmetry breaking, a massive $Z'$ gauge boson with non-universal couplings to quarks and leptons is generated by the mixing with the fourth family [2].

In such a model [2], the connection between non-universal $Z'$ couplings and the origin of Yukawa couplings may have interesting experimental implications. For example, some time ago, the LHCb Collaboration [3] and other experiments reported a number of anomalies in $B \to K^{(*)} l^+ l^-$ decays such as the $R_K$ and $R_{K^*}$ ratios of $\mu^+ \mu^-$ to $e^+ e^-$ final states, which are observed to be about 80% of their expected values with a $2.5\sigma$ deviation from the SM. Such anomalies may be accounted for by a new physics operator of the form $[4][12] \bar{b}_L \gamma^\mu s_L \bar{\mu}_L \gamma^\nu \mu_L$, with a coefficient $\Lambda^{-2}$ where $\Lambda \sim 30$ TeV. This hints that there may be new physics arising from the non-universal couplings of leptoquarks and/or $Z'$ in order to generate such an operator.

This observation motivated many papers on non-universal $Z'$, many of them concerned with $U(1)'$ anomaly cancellation. In the above approach [2], in which there are no chiral fermions which carry $U(1)'$ (only the $U(1)'$ charged vector-like fourth family) then anomaly cancellation is automatic, and non-universality is induced by mixing, making this a very natural and attractive possibility. Moreover, the resulting connection of the non-universal induced $Z'$ couplings with Yukawa matrices [2], is interesting. However, such a model raises other questions, such as what is the origin of the vector-like fourth family with $U(1)'$ charges, and why do they mix with the chiral quarks and leptons?

In this paper we take the next step in the development of such an approach to flavour, and suppose that the vector-like fourth family is identified as a Kaluza-Klein (KK) excitation of quarks and leptons which exist in a 5d bulk. The origin of the $U(1)'$ gauge symmetry in such an approach is rather subtle since we require the chiral quarks and leptons to be $U(1)'$ isocharge zero while their KK modes must include $U(1)'$ isocharged states. To address this, we shall suppose that the $U(1)'$ arises from a new gauged $SO(3)$ isospin in 5d, with the 5d quarks and leptons being assigned to $SO(3)$ isospin triplets, where each triplet decomposes into three states with $U(1)'$ isocharge $\pm 1, 0$. The idea is that the isocharge zero state contains a massless mode, while the iso-charged states have only heavy KK modes. Such a framework has the nice feature that the scalar $\phi$ which breaks the $U(1)'$ and yields the $Z'$, may originate as the fifth component of the 5d $SO(3)$ gauge field, according to a sort of “gauge-Higgs” unification [13][22]. In particular we shall follow the $SO(3)$ example in [22], where the “gauge” refers to the $SO(3)$ and the “Higgs” refers to the $\phi$ scalar.
In this way we are led to a simple ultraviolet completion of the vector-like family model in which the quarks and leptons of the SM are extended into the 5d bulk, while the SM Higgs remain as 4d brane fields. The hierarchies of Yukawa couplings are accounted for by assuming hierarchies in the 5d quark and lepton Dirac masses, somewhat analogous to the way that Yukawa hierarchies are generated in a 5d Randall-Sundrum set-up with a warped extra dimension \cite{23,24}, but here implemented with a flat extra dimension. However there are other important differences. While small mass differences in Randall-Sundrum can lead to large hierarchies via their effect on the fermion wavefunction profiles, here we require large 5d mass hierarchies which influence the Yukawa couplings directly, via seesaw type diagrams, with the heavy fermions as messengers. The two different set-ups, with a warped or a flat extra dimension, are of course experimentally distinguishable, for example we do not predict a KK graviton here. Also the mass spectrum of the KK fermion modes is quite different. And of course, here we will have a non-universal $Z'$ with experimental implications for flavour changing and non-universality.

The origin of neutrino masses in this set-up is also quite interesting since the usual type I seesaw mechanism cannot be implemented due to the absence of Majorana masses in 5d. Instead we shall rely on the recently proposed type Ib seesaw mechanism \cite{25}, where heavy Dirac KK neutrino masses can yield small physical Majorana neutrino masses.

The outline of the remainder of the paper is as follows. In section 2 we define the 5d model, assuming zero 5d fermion masses, and show how Yukawa couplings originate. In section 3 we show how the introduction of hierarchical 5d fermion masses can lead to Yukawa hierarchies and small CKM mixing angles. In section 4 we show how neutrino Majorana masses can arise from KK Dirac neutrinos, via the type Ib seesaw mechanism. In section 5 we discuss non-universal $Z'$ couplings and phenomenology. Section 6 concludes the main body of the paper. Appendix A details the $S^1/(\mathbb{Z}_2 \times \mathbb{Z}'_2)$ orbifold. Appendix B discusses the $SO(3)$ decomposition. Appendix C defines the Higgs fields on the branes and shows how the $U(1)'$ neutral Higgs components gain large masses.

## 2 The 5d Standard Model with gauged $SO(3)$ isospin

Suppose that the Standard Model (SM) is extended into a flat 5d spacetime, where each 5d quark and lepton field is assumed to be an isotriplet under a new gauged $SO(3)$ isospin. This is not weak isospin, nor is it a family symmetry, it is a completely new degree of freedom carried by each 5d multiplet $Q_i^\alpha, u_i^\alpha, d_i^\alpha, L_i^\alpha, e_i^\alpha$, where $i = 1, 2, 3$ is a family index and $\alpha = 1, 2, 3$ is a new $SO(3)$ index. The extra dimension $y$ is orbifolded as $S^1/(\mathbb{Z}_2 \times \mathbb{Z}'_2)$, resulting in two 4d branes, one at $y = 0$ and the other at $y = \pi R/2$, connected via the 5d bulk (see Appendix A for details). The quarks and leptons live in the bulk in irreducible representations of the 5d Lorentz group $SO(1, 4)$ which is broken to the standard one $SO(1, 3)$. The fields decompose into the standard representations, as described in Appendix A. We also assume that the SM gauge symmetry $SU(3)_C \times SU(2)_L \times U(1)_Y$ lives in the bulk, together with the gauged isospin symmetry $SO(3)$, while the Higgs doublets live on the 4d branes.

This extended symmetry, 5d Lorentz and $SO(3)$ gauged isospin, is broken with independent $SO(3)$ boundary conditions at each brane as follows:

$$P_0 = I, \quad P_{\pi R/2} = \text{diag}(-1, 1, -1),$$

(1)
where the SO(3) decomposition under $U(1)'$ is detailed in Appendix B, the key result being that each SO(3) isotriplet decomposes into three states with $U(1)'$ isocharges $+1, 0, -1$. The SO(3) gauge fields in the bulk have the boundary conditions shown in Table 1 which leads to a preserved $U(1)'$ 4d massless gauge boson, plus extra KK gauge boson excitations, plus the fifth scalar components of the gauge fields which are all heavy KK modes, with one of them acquiring a VEV and breaking the gauged $U(1)'$. The SM fermions, which live in the bulk as SO(3) triplets, are assigned a parity under each boundary condition as shown in Table 1, leading to massless modes consisting of the usual three chiral families, which are all neutral under the $U(1)'$ (i.e. have isocharge zero) plus their KK excitations (both charged and neutral under $U(1)'$). We also introduce a 5d neutrino field which transforms as a SM and SO(3) singlet, with the boundary conditions shown in Table 1, such that no massless modes are present; these heavy KK neutrinos play the role of “right-handed neutrinos” in the seesaw mechanism, although in this case, being KK modes, they are heavy Dirac fermions (see later).

Each bulk field can be expanded as a sum of their modes [26,27]. First let us decompose the SO(3) gauge vector $A_M$ field,

$$A_M(x, y) → A_\mu^0(x, y) = \sqrt{\frac{2}{\pi R}} \sum_{n=0}^{\infty} (A_\mu^0)^{(2n)}(2n)(x) \cos \frac{2ny}{R},$$

$$A_\mu^\pm(x, y) = \sqrt{\frac{2}{\pi R}} \sum_{n=0}^{\infty} (A_\mu^\pm)^{(2n+1)}(2n+1)(x) \cos \frac{(2n+1)y}{R},$$

$$A_5^0(x, y) = \sqrt{\frac{2}{\pi R}} \sum_{n=0}^{\infty} (A_5^0)^{(2n+2)}(2n+2)(x) \sin \frac{(2n+2)y}{R},$$

$$A_5^\pm(x, y) = \sqrt{\frac{2}{\pi R}} \sum_{n=0}^{\infty} (A_5^\pm)^{(2n+1)}(2n+1)(x) \sin \frac{(2n+1)y}{R}. \quad (2)$$

The quark and lepton electroweak doublets ($F = Q, L$) (dropping the flavour index $i$ and the SO(3) index $\alpha$) are decomposed in 4d as,

$$F(x, y) → F_L^\pm(x, y) = \sqrt{\frac{2}{\pi R}} \sum_{n=0}^{\infty} (F_L^\pm)^{(2n+1)}(2n+1)(x) \cos \frac{(2n+1)y}{R},$$

$$F_L^0(x, y) = \sqrt{\frac{2}{\pi R}} \sum_{n=0}^{\infty} (F_L^0)^{(2n)}(2n)(x) \cos \frac{2ny}{R},$$

$$F_R^\pm(x, y) = \sqrt{\frac{2}{\pi R}} \sum_{n=0}^{\infty} (F_R^\pm)^{(2n+1)}(2n+1)(x) \sin \frac{(2n+1)y}{R},$$

$$F_R^0(x, y) = \sqrt{\frac{2}{\pi R}} \sum_{n=0}^{\infty} (F_R^0)^{(2n+2)}(2n+2)(x) \sin \frac{(2n+2)y}{R}, \quad (3)$$

where the isoneutral left-handed doublets ($F_L^0 = Q_L^0, L_L^0$) clearly have zero modes for $n = 0$. The quark and lepton electroweak singlets ($f = u, d, e$) (again dropping the flavour index $i$ and the SO(3) index $\alpha$) are chosen to have the opposite parity at the zero
Table 1: The field content of the model, comprising three 5d SM fermion families $Q_i$, $u_i$, $d_i$, $L_i$, $e_i$, plus one singlet neutrino $\nu$, plus the 5d $SO(3)$ gauge field $A_M$, with their decomposition under the orbifold breaking. The index $i = 1, 2, 3$ is a family index not an $SO(3)$ index, i.e. there are three families of $SO(3)$ isotriplets. When the $SO(3)$ is broken to a $U(1)'$ by the orbifold, this will yield a massless neutral fermion (under the $U(1)'$) for each fermion family. The fifth component of the $SO(3)$ gauge field $A_5^\pm$ (charged under the $U(1)'$) is identified as a massive 4d scalar, whose VEV will eventually break the $U(1)'$, yielding a massive $Z'$. The 5d SM gauge fields are not displayed explicitly here. The 4d scalar Higgs doublets on the branes are also shown, with $H_{u,d}$ on the zero brane and $H'_{u,d}$ on the other brane.
brane, as compared to the doublets above, so their 4d profiles are,

\[
f(x, y) \rightarrow f_R(x, y) = \sqrt{\frac{2}{\pi R}} \sum_{n=0}^{\infty} (f_R^x)^{(2n+1)}(x) \cos \frac{(2n+1)y}{R},
\]

\[
f_R^0(x, y) = \sqrt{\frac{2}{\pi R}} \sum_{n=0}^{\infty} (f_R^0)^{(2n)}(x) \cos \frac{2ny}{R},
\]

\[
f_L(x, y) = \sqrt{\frac{2}{\pi R}} \sum_{n=0}^{\infty} (f_L^x)^{(2n+1)}(x) \sin \frac{(2n+1)y}{R},
\]

\[
f_L^0(x, y) = \sqrt{\frac{2}{\pi R}} \sum_{n=0}^{\infty} (f_L^0)^{(2n+2)}(x) \sin \frac{(2n+2)y}{R},
\]

so that isoneutral right-handed singlets \((f_R^0 = u_R^0, d_R^0, e_R^0)\) have massless zero modes for \(n = 0\). One neutrino field, a singlet under all gauge groups, decomposes in 4d as,

\[
\nu(x, y) \rightarrow \nu_L(x, y) = \sqrt{\frac{2}{\pi R}} \sum_{n=0}^{\infty} (\nu_L)^{(2n+1)}(x) \cos \frac{(2n+1)y}{R}
\]

\[
\nu_R(x, y) = \sqrt{\frac{2}{\pi R}} \sum_{n=0}^{\infty} (\nu_R)^{(2n+1)}(x) \sin \frac{(2n+1)y}{R},
\]

so that the zero modes form a single massive Dirac KK state \((\nu_L, \nu_R)\), as indeed do all the higher KK modes. Indeed all the heavy KK modes of all the fermions pair up into massive Dirac states in a similar way, but it is most simply seen with the neutrinos which have no massless modes (unlike the other electrically charged fermions which all contain massless modes as well as heavy KK modes).

The Higgs doublets are located on the 4d branes, so they will not have any KK mode expansions. We desire two Higgs doublets \(H_{u,d}\) to be located at the zero brane, each with a \(U(1)^1\) isocharge of \(-1\), which would forbid usual Higgs Yukawa couplings (since the massless chiral quarks and leptons are neutral), but which will allow effective Yukawa couplings to be generated when the \(U(1)^1\) is broken, via their coupling to isocharged KK states, as discussed later. In order to achieve this, it is actually necessary to introduce complete \(SO(3)\) triplets of Higgs \(H_{u,d}\) at the zero brane (where the \(SO(3)\) is unbroken) plus an additional a pair of Higgs doublets \(H_{u,d}^{\phi}\) at the other brane, which are neutral under \(U(1)^1\), and serve to give a large mass to the unwanted neutral components of the triplet at the zero brane. This mechanism is discussed in detail in Appendix C.

The 5d Lagrangian for these fields is, including the Higgs \(H_{u,d}\) at the zero brane\(^3\)

\[
\mathcal{L}_{5d} = i\bar{Q}_i\gamma^M D_M Q_i + i\bar{u}_i\gamma^M D_M u_i + i\bar{d}_i\gamma^M D_M d_i
\]

\[
+ i\bar{L}_i\gamma^M D_M L_i + i\bar{e}_i\gamma^M D_M e_i + i\bar{\nu}\gamma^M D_M \nu
\]

\[
+ \delta(y)\left[D_M H_u(D_M H_u) + D_M H_d(D_M H_d) + \frac{\delta(y)}{A} \left[y_{ij}^L H_u u_j + y_{ij}^L H_d d_j + y_{ij}^L H_d e_j + y_{ij}^L H_u \nu + y_{ij}^L H_d \nu \right]
\]

\(^3\)The mass dimensionality of each of the 5d fields is \([A_M] = 3/2\) for gauge vectors, \([F] = 2\) for fermions and \([H] = 1\) for brane scalars.
Figure 1: Fixed branes (locating the Higgs) at $y = 0, \pi R/2$ and the normalised wavefunction squared $|\psi|^2$ profiles for the lowest bulk modes. The $H_{u,d}^-$ are the physically relevant Higgs doublets renamed $H_{u,d}$ in the text. The massless $n = 0$ modes $A_0^0, F_L^0, f_R^0$ are isoneutral (isocharge zero) and correspond to the horizontal black line at $|\psi|^2 = 0.5$. Their isoneutral $n = 1$ KK modes have square wavefunctions depicted by the blue curve. Other $n = 0$ isoneutral modes are massive KK states shown by the brown curve. The $n = 0$ isocharged square wavefunctions are massive KK modes indicated by the green, red curves which vanish on the branes at $y = 0, \pi R/2$, respectively.

where the $y^{ij}$ are flavour matrices.

We now turn to the generation of the Yukawa couplings. This is non-trivial since the massless mode quarks and leptons have zero $U(1)'$ charge, and are hence forbidden to couple to the 4d Higgs $H_{u,d}$, which are charged under $U(1)'$, since the neutral Higgs components gain large masses by the mechanism in Appendix C, and so will not develop VEVs. The 4d effective theory relevant for the generation of Yukawa couplings will consist of the massless quark and lepton modes coupling to the 4d Higgs fields and the heavy KK modes. The SM field content lies in the zero modes, where we relabel the physically relevant fields as in Table 2. We shall assume that the field $\phi_{KK}$ with $U(1)'$ charge 1 gets a VEV and spontaneously breaks $U(1)'$, resulting in a massive $Z'$ plus a massive singlet Higgs field. Then the terms relevant for the generation of effective Yukawa couplings involve the fields in Table 2.

The couplings relevant for the generation of effective zero mode quark Yukawa couplings involving the fields in Table 2 are given by,

$$
\mathcal{L}_{0Q} = \left( \frac{2}{\pi R} \right) \frac{1}{\Lambda} \sum_n \int_0^{\pi R/2} dy \ \delta(y) \cos \left( \frac{2n + 1}{R} y \right) \left[ y^{ij} (Q_{iLKK}^\dagger H_u u_{jR} + Q_{iL}^\dagger H_u u_{jRKK}) \right] + g\sqrt{R} \left( \frac{2}{\pi R} \right)^{3/2} \int_0^{\pi R/2} dy \ \sin \left( \frac{2n + 1}{R} y \right) \cos \left( \frac{2n + 1}{R} y \right) \left[ Q_{iL}^\dagger \phi_{KK} Q_{iRKK} + u_{iLKK}^\dagger \phi_{KK} u_{iR} \right] + u \leftrightarrow d,
$$

(7)
Table 2: Field content in the effective 4d theory and their mode origin in the 5d expansion. All 4d fermion fields are left-handed Weyl spinors but they originate from 5d Dirac fermion modes with left (L) and right (R) handed components as shown in the last column (where the R components have been CP conjugated to yield left-handed Weyl spinors). The left-handed SM fermion states without a KK subscript correspond to the lowest Kaluza Klein modes having zero KK mass contributions in the 4d effective theory. We only show the KK fermion modes with positive \( U(1)' \) charge since they play a role in generating quark and lepton Yukawa couplings. There will be other KK fermion modes (not displayed) of all three isocharges \( \pm 1, 0 \), arising from \( SO(3) \) triplets, which similarly form massive vector-like pairs of left-handed Weyl spinors with conjugate quantum numbers. For example, we display \( L'_lK \), which has negative \( U(1)' \) isocharge, since it plays a role in the type Ib seesaw mechanism. The neutrinos \( \nu_KK \) arising from \( SO(3) \) singlets do not have any massless modes. The spin-1 \( Z'_\mu \) field and the complex scalars \( \phi_KK \) originate from the 5d \( SO(3) \) gauge field. The two scalar Higgs doublets \( H_u \equiv H_u^-, \quad H_d \equiv H_d^- \) are the isocharge negative 4d brane fields arising from the isotriplet Higgs on the zero brane.

where $g$ is the $U(1)'$ gauge coupling constant. For simplicity, we can just work with the $n = 0$ mode and integrate out the 5th dimension,

$$
\mathcal{L}_{0Q} = \frac{2}{\pi R \Lambda} \left[ y_u^i (Q^\dagger_{iLKK} H_u u_{jR} + Q^\dagger_{iL} H_u u_{jRKK}) \right] \\
+ g \left( \frac{2}{\pi} \right)^{3/2} \left[ Q^\dagger_{iL} \phi_{KK} Q_{iRKK} + u_{iRKK}^\dagger \phi_{KK} u_{iR} \right] \\
+ u \leftrightarrow d.
$$

The charged lepton couplings are built in a similar way, leading to

$$
\mathcal{L}_{0L} = \frac{2}{\pi R \Lambda} \left[ y_e^i (L^\dagger_{iLKK} H_d e_{jR} + L^\dagger_{iL} H_d e_{iRKK}) \right] \\
+ g \left( \frac{2}{\pi} \right)^{3/2} \left[ L^\dagger_{iL} \phi_{KK} L_{iRKK} + e_{iRKK}^\dagger \phi_{KK} e_{iR} \right].
$$

By integrating out the mediators we obtain the effective Yukawa terms

$$
\mathcal{L}_Y = \frac{8g}{\pi \Lambda} \left( \frac{2}{\pi} \right)^{3/2} \langle \phi_{KK} \rangle \left[ y_u^i Q^\dagger_{iL} H_u u_{jR} + y_d^i Q^\dagger_{iL} H_d d_{jR} + y_e^i L^\dagger_{iL} H_d e_{jR} \right].
$$

The quarks and charged lepton Yukawa couplings are mediated by each right and left handed fermion, as well as the Higgs KK modes, as shown in figure 2. Unfortunately, the theory so far does not provide any understanding of the quark and lepton mass hierarchies, it simply reparametrises the Standard Model Yukawa couplings in terms of the 5d Yukawa couplings. This deficiency is remedied in the next section.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure2.png}
\caption{Diagrams for effective 4d up-type quark Yukawa couplings (see Table 2 for notation). Similar diagrams with $u \rightarrow d$ give the down-type Yukawa couplings. Charged lepton Yukawa couplings arise from similar diagrams involving $L_i, e_j$, together with their respective leptonic KK messengers, and $H_d$.}
\end{figure}

### 3 Explicit 5d masses and Yukawa hierarchies

So far we have been ignoring the effect of the 5d scalar and fermion masses, and the analysis in the previous section implicitly assumes these masses to be zero. However the 5d fermions are always Dirac fermions, therefore it is possible to write explicit mass terms for each 5d fermion. Similarly we can include 5d scalar Higgs doublet masses. Therefore in addition to the terms in eq. 6, one can write explicit 5d masses as

$$
\mathcal{L}_{5dm} = \overline{Q}_{iL} M^{ij}_{Q} Q_{j} + \overline{u}_{i} M^{ij}_{u} u_{j} + \overline{d}_{i} M^{ij}_{d} d_{j} + \overline{L}_{i} M^{ij}_{L} L_{j} + \overline{e}_{i} M^{ij}_{e} e_{j} + \overline{\nu} M_{\nu} \nu,
$$

\[ \text{(11)} \]
where we can diagonalize the matrix from the start so that $M^{ij} = M^i \delta^{ij}$.

This 5d mass will change the spectrum of the KK masses. It does not change the mode profiles in eq. 3. However, the addition of the new parameter changes the mass spectrum of the KK modes. The zero modes remain massless 28. The scalar and fermion massive KK modes change their mass as 29

$$\frac{1}{R} \rightarrow \sqrt{R^{-2} + M_i^2}. \quad (12)$$

The effective Yukawa terms become

$$\mathcal{L}_Y = \frac{4g}{\pi R \Lambda} \left( \frac{2}{\pi} \right)^{3/2} \langle \phi_{KK} \rangle \times \left[ \left( \pi R / 2 + (R^{-2} + (M_Q^i)^2)^{-1/2} + (R^{-2} + (M_u^i)^2)^{-1/2} \right) y_u^{ij} Q_{iL}^j H_u u_{jR} \\
+ \left( \pi R / 2 + (R^{-2} + (M_Q^i)^2)^{-1/2} + (R^{-2} + (M_d^i)^2)^{-1/2} \right) y_d^{ij} Q_{iL}^j H_d d_{jR} \\
+ \left( \pi R / 2 + (R^{-2} + (M_L^i)^2)^{-1/2} + (R^{-2} + (M_e^i)^2)^{-1/2} \right) y_e^{ij} L_{iL}^j H_d e_{jR} \right]. \quad (13)$$

Note that the relative contributions of each fermion and Higgs mediated diagram has changed, depending on the values of the 5d masses. Let us make the following assumptions about the 5d masses:

- one of the three fermion families (say the third family) has the lightest 5d mass, as compared to the first two families, $M_3 \ll M_{1,2}$
- within the third fermion family, the hierarchies of 5d masses satisfy, $1/R \lesssim M_{Q_3} \ll M_{d_3} \ll M_{u_3}$ and $1/R \lesssim M_{L_3} \ll M_{e_3}$

With these assumptions the dominant contributions to the Yukawa couplings arise from the left diagram in figure 2 which is mediated by the third family doublets $Q_{3KK}$ in the case of quarks, or $L_{3KK}$ in the case of the charged leptons. The interactions involving the lightest $Q_{3KK}$ and $L_{3KK}$ states are just a subset of the terms in Eqs. 8, 9

$$\mathcal{L}_{Q_{3KK}} = \frac{2}{\pi R \Lambda} \left[ y_u^{3j} (Q_{iLKK}^i H_u u_{jR}) + u \leftrightarrow d \right] + g \left( \frac{2}{\pi} \right)^{3/2} \left[ Q_{iL}^j \phi_{KK} Q_{3KK} \right], \quad (14)$$

$$\mathcal{L}_{L_{3KK}} = \frac{2}{\pi R \Lambda} \left[ y_e^{3j} (L_{iLKK}^i H_d e_{jR}) \right] + g \left( \frac{2}{\pi} \right)^{3/2} \left[ L_{iL}^j \phi_{KK} L_{3KK} \right]. \quad (15)$$

By integrating out the $Q_{3KK}$ and $L_{3KK}$ mediators we obtain the dominant effective Yukawa terms

$$\mathcal{L}_{Y_{3j}} = g \left( \frac{2}{\pi} \right)^{3/2} \frac{2}{\pi R \Lambda} \left[ \langle \phi_{KK} \rangle (R^{-2} + M_{Q_j}^2)^{-1/2} \right] \left[ y_u^{3j} Q_{iL}^i H_u u_{jR} + y_d^{3j} Q_{iL}^i H_d d_{jR} \right] \\
+ g \left( \frac{2}{\pi} \right)^{3/2} \frac{2}{\pi R \Lambda} \left[ \langle \phi_{KK} \rangle (R^{-2} + M_{L_j}^2)^{-1/2} \right] \left[ y_e^{3j} L_{iL}^i H_d e_{jR} \right]. \quad (16)$$

The above Yukawa matrices consist of only the third row elements being non-zero. Ignoring the subdominant couplings below, they may be diagonalised by rotating $u_{jR}, d_{jR}, e_{jR}$
to yield only non-zero (3,3) elements corresponding to the $t, b, \tau$ masses, respectively. This explains why the third family is the heaviest one, which is due to $Q_{3KK}$ and $L_{3KK}$ being the lightest KK states.

To populate the more than just the (3,3) elements of the Yukawa matrices, we must consider the effect of the next lightest states, namely the rest of the third family $d_{3KK}, u_{3KK}, e_{3KK}$ states. We first write down the interactions involving $d_{3KK}, u_{3KK}, e_{3KK}$, which is another subset of the terms in Eqs.8,9

$$\mathcal{L}_{q_{3KK}} = \frac{2}{\pi R \Lambda} \left[ y_u^3 (Q_{3u}^1 H_u u_{3RRKK}) + u \leftrightarrow d \right] + g \left( \frac{2}{\pi} \right)^{3/2} \left[ u_{3LKK}^\dagger \phi_{KK} u_{3R} + u \leftrightarrow d \right],$$

(17)

$$\mathcal{L}_{e_{3KK}} = \frac{2}{\pi R \Lambda} \left[ y_e^3 (L_{3e}^1 H_d e_{3RRKK}) \right] + g \left( \frac{2}{\pi} \right)^{3/2} \left[ e_{3LKK}^\dagger \phi_{KK} e_{3R} \right].$$

(18)

By integrating out the $d_{3KK}, u_{3KK}, e_{3KK}$ mediators we obtain the sub-dominant effective Yukawa terms

$$\mathcal{L}_{Y_{33}} = g \left( \frac{2}{\pi} \right)^{3/2} \frac{2}{\pi R \Lambda} \left[ \langle \phi_{KK} \rangle (R^{-2} + M_{u_{3}}^2)^{-1/2} \right] \left[ y_u^3 Q_{3u}^1 H_u u_{3R} \right] + u \leftrightarrow d$$

$$+ g \left( \frac{2}{\pi} \right)^{3/2} \frac{2}{\pi R \Lambda} \left[ \langle \phi_{KK} \rangle (R^{-2} + M_{d_{3}}^2)^{-1/2} \right] \left[ y_e^3 L_{3e}^1 H_d e_{3R} \right]$$

(19)

The Yukawa matrices in LR convention, resulting from the third family KK mediators (assumed to be the lightest ones and the only ones considered so far), now consist of the dominant third row elements from Eq.16 and the sub-dominant third column elements from Eqs.19, i.e. only the third row and third column have non-zero elements. In the basis where the dominant third row is diagonalised, the Yukawa matrices may be expressed in the form\(^4\) ignoring overall factors and the compactification scale,

$$Y_{ij}^u = \begin{pmatrix} 0 & 0 & 0 \\ 0 & x_{22}^u & x_{23}^u \\ 0 & x_{32}^u & x_{33}^u \end{pmatrix} \frac{g \langle \phi_{KK} \rangle}{M_{u_{3}}} + \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & y_{33}^u \end{pmatrix} \frac{g \langle \phi_{KK} \rangle}{M_{Q_{3}}}$$

$$Y_{ij}^d = \begin{pmatrix} 0 & 0 & 0 \\ 0 & x_{12}^d & x_{13}^d \\ 0 & x_{22}^d & x_{23}^d \end{pmatrix} \frac{g \langle \phi_{KK} \rangle}{M_{d_{3}}} + \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & y_{33}^d \end{pmatrix} \frac{g \langle \phi_{KK} \rangle}{M_{Q_{3}}}$$

$$Y_{ij}^e = \begin{pmatrix} 0 & 0 & 0 \\ 0 & x_{12}^e & x_{13}^e \\ 0 & x_{22}^e & x_{23}^e \end{pmatrix} \frac{g \langle \phi_{KK} \rangle}{M_{e_{3}}} + \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & y_{33}^e \end{pmatrix} \frac{g \langle \phi_{KK} \rangle}{M_{L_{3}}}$$

(20)

where the Yukawa couplings $x_{ij}^{u,d,e}$, $y_{ij}^{u,d,e}$ are linear combinations of the original Yukawa couplings to the third family KK modes $y_{ij}^{u,d,e}$, $y_{ij}^{u,d,e}$, and are hence expected to be of order unity. We also assume that they are defined to absorb all the prefactors, which are

---

\(^4\)To arrive at this form, starting from Yukawa matrices with only non-zero third rows and third columns, we have first rotated $(u_{1R}, u_{2R})$, $(d_{1R}, d_{2R})$, $(e_{1R}, e_{2R})$ to put zeroes in the first column, then rotated $(Q_1, Q_2)$ to set $Y_{ij}^Q = 0$, then finally we have rotated $(u_{2R}, u_{3R})$, $(d_{2R}, d_{3R})$, $(e_{2R}, e_{3R})$ to diagonalise the dominant third row.
also of order unity. The Yukawa hierarchy in this model is generated by the previously
assumed mass hierarchy of 5d masses, $M_{Q_3} \ll M_{d_3} \ll M_{u_3}$, and $M_{L_3} \ll M_{e_3}$, called
“messenger dominance” in [1]. This implies that the second matrices on the right-hand
side of the equalities in Eq.20 dominate, giving the dominant third family masses $m_t, m_b, m_\tau$. The sub-dominant first matrices on the right-hand side of the equalities in Eq.20 are
responsible for the second family masses with $m_c/m_t \sim M_{Q_3}/M_{u_3}$, $m_s/m_b \sim M_{Q_3}/M_{d_3}$,
with a more pronounced mass hierarchy in the up sector than the down sector. It also
implies non-zero quark mixing angles, with small values of the CKM elements $|V_{ub}| \sim |V_{cb}| \sim 1$. However $|V_{ub}|$ is too large and the smallness of the Cabibbo angle is not explained with $|V_{us}| \sim 1$. It also implies a natural
lepton mass hierarchy $m_\mu/m_\tau \sim M_{L_3}/M_{e_3}$, with non-zero charged lepton contributions
to leptonic mixing angles analogous to the quark ones. However the neutrino sector will
dominantly contribute to leptonic mixing angles as discussed in the next section. At this
stage the first family quarks and leptons are massless, but will develop small masses when
the first and/or second family KK mediators are included.

4 Neutrino Majorana masses from KK Dirac neutrinos

Finally, to generate the neutrino masses, we follow a somewhat different procedure to the
case of charged lepton and quark masses. The Higgs doublets do not couple to the
massless chiral lepton doublets $L_i$ to the neutrino singlets $\nu$, as seen in Eq.13, for the
same reason that SM Yukawa couplings are not allowed, namely that the Higgs carry
$U(1)'$ charge while the SM chiral fermions do not. In the case of charged lepton and
quark masses, such Yukawa couplings are mediated by $U(1)'$ charged KK excitations,
arising from the $SO(3)$ lepton and quark triplets. However, in the case of neutrinos, the
5d neutrino singlets $\nu$ are chosen to be $SO(3)$ singlets, and do not have any zero modes,
and therefore the KK excitations are neutral under $U(1)'$ and so do not couple to $L_i$. In
this case the KK mediation arises from the following couplings,

$$\mathcal{L}_{0\nu} = \frac{2\pi R\Lambda}{\pi^5 A^3} \left[ y_{i\nu} L_{iKK}^\dagger H_u \nu_{RKK} + y_{j\nu} L_{jKK}^\dagger \tilde{H}_d \nu_{LKK} \right], \quad (21)$$

where $\tilde{H}_d$ is the CP conjugate of the Higgs doublet $H_d$, and hence $\tilde{H}_d$ will have the same
hypercharge as $H_u$ but opposite isocharge. The $L_{iKK}$ and $L_{jKK}$ have opposite $U(1)'$
charges but both will couple to the neutral massless chiral lepton doublet $L_i$. It is worth
to note that these couplings involve two KK excitations in each term. Also note that two
different Higgs doublets are involved here, which couple to the two different KK lepton
doublets. The two different KK neutrino fields above, $\nu_{LKK}$ and $\nu_{RKK}$, form a single
heavy Dirac KK mass, which may be integrated out to generate the effective neutrino operators,

$$\mathcal{L}_{0\nu} = \frac{64\pi R\Lambda}{\pi^5 A^3} \langle \phi_{KK}^+ \phi_{KK}^+ \rangle y_{i\nu} y_{j\nu} L_{iL}^\dagger H_u \tilde{H}_d L_{jL}. \quad (22)$$

Note that this is not the usual Weinberg operator since it involves two different Higgs
doublets, so it is a new type of Weinberg operator, originating from a variant of the
type I see saw mechanism called the type Ib seesaw mechanism [25]. The new effective
dimension 5 operator is mediated by the Dirac KK neutrino modes, as shown in figure 3.
In fact this version of the type Ib seesaw mechanism is slightly different to that proposed in [25], since it involves two additional scalar singlets $\phi_{KK}\phi_{KK}^\dagger$, leading to additional mass suppression, but the basic features are the same: two different Higgs doublets with a single Dirac heavy neutrino mass mediating the diagram, leading to light effective Majorana neutrino masses. However, assuming zero 5d Dirac masses, the new mechanism does not so far explain the smallness of neutrino mass unless the compactification scale is quite high, or at least one of the Yukawa couplings is very small.

![Diagram](image)

Figure 3: Diagrams for the type Ib seesaw mechanism for neutrino masses.

Now including also the explicit 5d Dirac masses discussed in Eq. 11 of the previous section, the operator in Eq. 22 is generalised to

$$
\mathcal{L}_{0\nu} = \frac{32}{\pi^5 R^2 A^2} \langle \phi_{KK}\phi_{KK}^\dagger \rangle y_{i}\nu_{j}^\dagger L_{iL}^\dagger H_u H_d L_{jL} \times \\
(R^{-2} + (M_{\nu})^2)^{-1/2} \left( R^{-2} + (M_{L}^\dagger)^2 \right)^{-1/2} \left( R^{-2} + (M_{L})^2 \right)^{-1/2}.
$$

This leads to a general symmetric Majorana mass matrix for the neutrinos from a single pair of 5d Dirac neutrinos. There is now the opportunity to explain the smallness of neutrino mass even with a low compactification scale and Yukawa couplings of order unity, by assuming that one of the 5d Dirac masses is very large. For example the $(SO(3)$ singlet) 5d neutrino mass $M_{\nu}$ could be much larger than the $(SO(3)$ triplet) 5d lepton doublet masses, $M_{\nu} \gg M_{L}^\dagger$, leading to highly suppressed neutrino masses, as in the traditional type Ia seesaw mechanism. One may speculate on mechanisms which would result in a larger mass for the $SO(3)$ singlet than the $SO(3)$ triplet fermions, but that is beyond the scope of the present paper.

5 Non universal $Z'$ couplings and phenomenology

The terms that would generate an effective 4d $Z'$ coupling would be

$$
\mathcal{L}_{Z'} = g \left( \frac{2}{\pi} \right)^{3/2} \left[ \psi_{KK}^\dagger \psi_{KK} + \psi_{jKK}^\dagger \gamma_{\mu} Z_{\mu}^\prime \psi_{jKK} \right] + h.c.,
$$

(24)
Figure 4: Diagrams for the effective $Z'$ coupling to the isoneutral quark doublets $Q_{iL}$, mediated by the isocharged KK excitations (where $Z'$ only couples to isocharged states). Similar diagrams may be drawn for all the SM fermions $Q_{iL}, u_{iR}, d_{iR}, L_{iL}, e_{iR}$, which are isoneutral, with effective $Z'$ couplings mediated by their respective isocharged KK excitations.

where can be any $\psi = Q_L, u_R, d_R, L_L, e_R$. By integrating out the KK modes, as in fig. 4, we obtain the non universal corrections

$$L_{Z'} = g \left( \frac{2}{\pi} \right)^{3/2} \left[ \langle \phi_{KK} \phi_{KK}^\dagger \rangle (R^{-2} + M^2_{\psi_3})^{-1} \right] \psi_i^\dagger \gamma^\mu Z'_\mu \psi_i. \quad (25)$$

These $Z'$ couplings are not universal since we are assuming $M_{Q_3} \ll M_{d_3} \ll M_{u_3}$, and $M_{L_3} \ll M_{e_3}$, in order to generate the desired Yukawa hierarchies. Indeed the $Z'$ couplings are related to the Yukawa couplings as in [2]. The dominant $Z'$ couplings will be generated by the lightest messenger masses associated with the third family doublets $Q_3$ and $L_3$,

$$L_{Z'Q_3} = g \left( \frac{2}{\pi} \right)^{3/2} \left[ \langle \phi_{KK} \phi_{KK}^\dagger \rangle (R^{-2} + M^2_{Q_3})^{-1} \right] Q_3^\dagger L \gamma^\mu Z'_\mu Q_3^L \quad (26)$$

$$L_{Z'L_3} = g \left( \frac{2}{\pi} \right)^{3/2} \left[ \langle \phi_{KK} \phi_{KK}^\dagger \rangle (R^{-2} + M^2_{L_3})^{-1} \right] L_3^\dagger L \gamma^\mu Z'_\mu L_3^L.$$

Note that the prefactors in Eq. (26) are related to the square of the prefactors of the dominant Yukawa couplings in Eq. (16). Thus, this model not only explains the origin of the Yukawa couplings but also relates them to non universal $Z'$ couplings [2]. Unlike [2], this model is enhanced with extra dimensions, which explains the origin of the mediators and the $U(1)'$ breaking field $\phi$.

The non universal $Z'$ couplings in Eq. (26) may help to generate the non universal leptonic decays [3] which can’t be explained within the SM [30, 32]. Although the chiral fermions do not carry $U(1)'$ charges, the diagrams in Fig. 4 generate effective $Z'$ couplings to chiral fermions, via the KK messengers do carry $U(1)'$ charges (which are trivially anomaly free). The $Z'$ couplings in the above basis are dominated by left-handed couplings to the third family in Eq. (26), which we write approximately as [33],

$$y_t^2 g Z'_\mu Q_3^\dagger \gamma^\mu Q_3^L + y_\tau^2 g Z'_\mu L_3^\dagger \gamma^\mu L_3^L, \quad (27)$$

to emphasise the approximate relation to the top and tau Yukawa couplings, $y_t$ and $y_\tau$, resulting from Eq. (16). Flavour changing couplings involving the quark doublets...
\[ Q_{3L} = (t, b)^T, \quad Q_{2L} = (c, s)^T, \] will be generated when the Yukawa matrices in Eq. 20 are diagonalised,

\[ y_t^2 Z_\mu Q_{3L}^1 \gamma^\mu Q_{3L} \rightarrow V_{ts} Z_\mu Q_{3L}^1 \gamma^\mu Q_{2L}, \quad V_{ts}^2 Z_\mu Q_{2L}^1 \gamma^\mu Q_{2L}, \cdots \rightarrow V_{ts} Z_\mu Q_{1L}^1 \gamma^\mu s_L, \ldots \] (28)

Similarly the operator \( y_t^2 Z_\mu Q_{3L}^1 \gamma^\mu L_{L3} \) in Eq. 27 leads to flavour changing couplings involving the lepton doublets \( L_{3L} = (\nu_\tau, \tau)^T, \quad L_{2L} = (\nu_\mu, \mu)^T \), controlled by a left-handed lepton mixing \( \theta_{23}^e \),

\[ \theta_{23}^e y_t^2 Z_{\mu} L_{3L}^1 \gamma^\mu L_{2L} \rightarrow \theta_{23}^e y_t^2 Z_{\mu} L_{2L}^1 \gamma^\mu L_{2L} \rightarrow \theta_{23}^e y_t^2 Z_{\mu} L_{L3} \gamma^\mu \mu_L, \quad (\theta_{23}^e)^2 y_t^2 Z_{\mu} L_{L3} \gamma^\mu \mu_L \] (29)

where we have taken \( y_t \approx y \approx 1 \). The couplings in Eqs 28, 29 control the \( Z' \) exchange diagrams in Fig. 5 which contribute to \( R_{K^{(*)}} \) (left), to \( B_s \) mixing (centre) and to \( \tau \rightarrow \mu \mu \mu \) (right).

The \( Z' \) contributes to \( R_{K^{(*)}} \) at tree-level, via the (left) diagram in Fig. 5, where the requirement to explain the anomaly is, defining the couplings of the \( Z' \) to the relevant fermions as \( g_{\mu \mu} \) and \( g_{bs} \),

\[ \frac{g_{\mu \mu} g_{bs}}{M_{Z'}^2} \approx \frac{y_t^2 (\theta_{23}^e)^2 V_{ts}}{M_{Z'}^2} \approx \frac{1.1}{(35 \text{ TeV})^2} \] (30)

Since \( V_{ts} \approx 4.0 \times 10^{-2} \), this requires quite a large \( y_\tau \approx 1 \) (i.e. large \( \tan \beta = \langle H_u \rangle / \langle H_d \rangle \)) and a large mixing angle \( \theta_{23}^e \approx 0.1 \), together with a low mass \( M_{Z'} \approx 1 \text{ TeV} \), close to current LHC limits [34].

Now \( B_s \) mixing is mediated by tree-level \( Z' \) exchange as in the (centre) diagram in Fig. 5 leading to the 2015 bound [34],

\[ \frac{g_{bs} g_{bs}}{M_{Z'}^2} \approx \frac{V_{ts}^2}{M_{Z'}^2} \leq \frac{1}{(140 \text{ TeV})^2} \] (31)

leading to \( M_{Z'} \geq 5.6 \text{ TeV} \), in some tension with the \( R_{K^{(*)}} \) requirement above. However the stronger 2017 bound with scale of 770 TeV instead of 140 TeV implies a bound of \( M_{Z'} \geq 31 \text{ TeV} \), which is quite incompatible with the \( R_{K^{(*)}} \) requirement in Eq. 30.

Moreover \( \tau \rightarrow \mu \mu \mu \) is mediated by tree-level \( Z' \) exchange as in the (right) diagram in Fig. 5 leading to the bound [34],

\[ \frac{g_{\tau \mu} g_{\mu \mu}}{M_{Z'}^2} \approx \frac{(\theta_{23}^e)^3 y_t^4}{M_{Z'}^2} \leq \frac{1}{(16 \text{ TeV})^2} \] (32)
Writing \( g_{\tau \mu} = g_{\mu\mu} / \theta_{23}^e \), the bounds on \( B_s \) mixing and \( \tau \to \mu\mu\mu \) may be written as:

\[
\frac{g_{bs}}{M_{Z'}} \leq \frac{1}{(140 \text{ TeV})}, \quad \frac{g_{\mu\mu}}{M_{Z'}} \leq \frac{(\theta_{23}^e)^{1/2}}{(16 \text{ TeV})}
\]

which may be combined, leading to a bound\(^5\) on the contribution to \( R_{K^{(*)}} \)\(^{33,35} \),

\[
\frac{g_{\mu\mu} \cdot g_{bs}}{M_{Z'} \cdot M_{Z'}} \leq \frac{(\theta_{23}^e)^{1/2}}{(140 \text{ TeV})(16 \text{ TeV})} = \frac{(\theta_{23}^e)^{1/2}}{(47 \text{ TeV})^2}
\]

which is somewhat less than the \( \frac{1}{(35 \text{ TeV})^2} \) required in Eq.\(^30\) to explain the anomaly. Moreover, the stronger 2017 bound with scale of 770 TeV instead of 140 TeV implies a bound of \( \frac{1}{(111 \text{ TeV})^2} \), which is significantly less than the \( \frac{1}{(35 \text{ TeV})^2} \) required to explain the anomaly.

The \( R_{K^{(*)}} \) anomaly could be explained in this model, consistently with \( \tau \to \mu\mu\mu \), if the second lepton doublet messenger mass were assumed to be of the same order as that of the third family, namely \( M_{L_2} \sim M_{L_3} \ll M_{e_3} \), which would imply that a new \( Z' \) coupling to muons \( g_{\mu\mu} \) could arise independently of the \( \tau \) coupling \( g_{\tau\tau} \), removing the bound on \( g_{\mu\mu} \) in Eq.\(^33\). In this case the bound in Eq.\(^34\) would be evaded, and indeed \( \theta_{23}^e \) could be naturally very small, as expected, say of order \( V_{ts} \). However, in such a scenario, the smallness of the muon mass compared to the \( \tau \) mass could not be explained by the hierarchy of 5d Dirac masses, but instead would have to be accounted for by a tuning of Higgs Yukawa couplings, as in the Standard Model. Therefore, we would prefer that the \( R_{K^{(*)}} \) rate is much closer to the Standard Model prediction, so that we can provide a natural explanation of the smallness of the muon mass as being due to \( M_{L_3} \ll M_{e_3}, M_{L_2} \). In this preferred scenario, although we cannot explain the current \( R_{K^{(*)}} \) anomaly, nevertheless there can be non-zero contributions to all the three BSM processes in Fig.\(^5\) which could be all observed in the future.

6 Conclusion

In this paper we have proposed a theory of quark and lepton masses with non-universal \( Z' \) couplings based on a simple extension to the Standard Model in which quarks and leptons are promoted to 5d gauged \( SO(3) \) isospin triplets. We emphasise that this is not weak isospin, nor is it a family symmetry, it is a completely new degree of freedom carried by each 5d multiplet \( Q_{\alpha i}^\alpha, u_{\alpha i}^\alpha, d_{\alpha i}^\alpha, L_{\alpha i}^\alpha, e_{\alpha i}^\alpha \), where \( i = 1, 2, 3 \) is a family index and \( \alpha = 1, 2, 3 \) is a new \( SO(3) \) index. In the 4d effective theory, the \( SO(3) \) is broken to \( U(1)' \), under which the triplets carry isocharges \((+1, 0, -1)\). The breaking is achieved via the \( S^1/(\mathbb{Z}_2 \times \mathbb{Z}_2) \) orbifold, with \( U(1)' \) subsequently dynamically broken, resulting in a massive \( Z' \).

Quarks and leptons in the 5d bulk appear as massless modes, isoneutral under \( U(1)' \). The Higgs doublets are located on the brane and have isocharge \( \pm 1 \) (ignoring the heavier isoneutral Higgs doublets). There are zero Yukawa couplings to the Higgs, and zero couplings to \( Z' \), due to the \( U(1)' \) symmetry. However, after the \( U(1)' \) breaking, both Yukawa couplings and non-universal \( Z' \) couplings are generated by heavy Kaluza-Klein exchanges. This may be regarded as the ultraviolet completion of a model proposed some

\(^5\)I am grateful to E.Perdomo for pointing out this bound.
time ago based on a vector-like fourth family isocharged under a $U(1)'$, which mediates both Yukawa couplings and $Z'$ couplings for the chiral quarks and leptons, which are isoneutral under $U(1)'$, thereby relating such couplings. The idea here is that the fourth vector-like family is identified as a KK excitation along an extra 5th compact dimension.

However, such a KK interpretation required the introduction of the $SO(3)$ isospin, broken to $U(1)'$, to enable the combination of isoneutral chiral fermions and isocharged KK excitations. The presence of gauged $SO(3)$ enables the “gauge-Higgs unification” mechanism, whereby the isocharged Higgs singlet that breaks the $U(1)'$ originates from the fifth component of the $SO(3)$ gauge field, providing a satisfying mechanism for symmetry breaking. The hierarchical Yukawa couplings of charged fermions results from a hierarchy of 5d Dirac fermion masses, in particular, the lightest masses being associated with the third family quarks and leptons, with $1/R \lesssim M_{Q3} \ll M_{d3} \ll M_{u3}$, and $1/R \lesssim M_{L3} \ll M_{e3}$, where the two other families are assumed to have even heavier masses. Majorana neutrino mass and mixing arises from a novel type Ib seesaw mechanism, mediated by Kaluza-Klein Dirac neutrinos with large 5d Dirac masses $M_\nu \gg M_i$. This mechanism could be applied to any other extra dimensional and/or string model, in order to obtain Majorana neutrinos from a seesaw mechanism in which the mediators are Kaluza-Klein Dirac neutrinos.

In the present model, since each quark and lepton field forms a complete isospin triplet, $Q_\alpha^i, u_\alpha^i, d_\alpha^i, L_\alpha^i, e_\alpha^i$, each field will have three isocharges $(+1, 0, -1)$, with only the isoneutral ones having massless zero modes. However, for each flavour and isospin index $(i, \alpha)$, there will be an infinite KK tower of massive Dirac (or vector-like) states, providing a wealth of new states which could be discovered at future colliders, although given that the 5d masses of these states are very hierarchical, only the lightest ones above will be discovered to start with. Thus the lightest KK modes are the electroweak doublets and isotriplets $Q_{\alpha KK} = (T, B)^\alpha$ with mass $M_{Q3}$ and $L_{3KK} = (N, E)^\alpha$ with mass $M_{L3}$, which automatically respect a custodial $SU(2)$ symmetry, allowing the compactification scale to be as low as the direct collider limits on universal extra dimensions, around the TeV scale [37]. In the present model there also be an isotriplet of Higgs doublets $H_{u,d}$ on the zero brane plus an additional pair of isoneutral Higgs doublets $H_{u,d}^0$ on the other brane, all of which could be within experimental reach.

The non-universal $Z'$ couplings may contribute to semi-leptonic $B$ decay ratios $R_{K(\tau)}$ which violate $\mu - e$ universality, which in this model are related to the origin of the fermion Yukawa couplings. However, the natural expectation is that the presently indicated rate of $R_{K(\tau)}$ is too large to be explained in this model, although it could be observed at a lower rate in future, along with other BSM signals of $B_s$ mixing and $\tau \rightarrow \mu\mu\mu$.

In conclusion, we have extended the SM fermions into a flat 5d bulk, with Higgs doublets on the branes, in order to shed light on the origin of Yukawa couplings. We were led to introduce a new $SO(3)$ isospin under which fermions and Higgs are isotriplets, although extra isosinglet Higgs and isosinglet neutrinos were also introduced. We have assumed hierarchical 5d Dirac masses in order to account for the fermion mass hierarchies. However this is more than just a one-one reparametisation of the fermion masses by the 5d Dirac masses. With the simple assumptions $1/R \lesssim M_{Q3} \ll M_{d3} \ll M_{u3}$, and $1/R \lesssim M_{L3} \ll M_{e3}$ we have reproduced all the charged fermion mass hierarchies and generated small quark mixing predominantly from the down quark sector. Majorana neutrino masses arise from Dirac KK neutrino exchange, via a type Ib seesaw mechanism,
with $M_\nu \gg M^i_L$ accounting for the smallness of neutrino mass.

Finally we note that, whilst similar results could also be achieved in 4d by adding a fourth vector-like family to the SM, we have shown that by introducing an extra dimension and 5d isospin $SO(3)$ we can explain the origin of the fourth vector-like family (and the fifth one which is necessary to obtain non-zero first family quark and lepton masses) by the very simple and elegant extension to the SM shown in Table 1. Thus, the extra vector-like families are not introduced in an ad hoc way but instead emerge as KK excitations. Moreover, the experimental implications of such a novel theory of flavour are very distinctive, being distinguishable from universal extra dimensions due to: the presence of the gauged $SO(3)$, broken to $U(1)'$ and leading to the $Z'$; the characteristic 5d Dirac mass pattern above; and the rich spectrum of Higgs doublets on the branes. It would clearly be interesting to explore the phenomenology of this model further.

A $S^1/(\mathbb{Z}_2 \times \mathbb{Z}_2')$ orbifold

We assume a 5d spacetime, with an extra spatial dimension $y$. The extra dimension is compactified as an orbifolded circle with the identifications

\[
y \sim y + 2\pi R, \\
y \sim -y,
\]

which defines the orbifold geometry. The orbifolding leaves 2 fixed points

\[
\bar{y} = \{0, \pi R/2\},
\]

which allow boundary conditions on the fields. Any arbitrary field $\Phi(x, y)$ must comply with eq. 35 up to a gauge transformation, which defines the boundary conditions since

\[
\Phi(x, y) = P_0 \Phi(x, -y), \quad \Phi(x, y + \pi R/2) = P_{\pi R/2} \Phi(x, -y + \pi R/2)
\]

so that the two independent boundary conditions satisfy $P^2_{0,\pi R/2} = 1$ and they belong to the extended gauge group. Each condition corresponds to each $\mathbb{Z}_2$.

We locate all fields in the bulk which have to belong to irreducible representations of the Lorentz group $SO(1, 4)$. It is important to understand how each field transforms under the orbifolded parity.

The orbifold operation is the 5th parity operator $P_5$ which is accompanied by a gauge transformation $P_{0,\pi R}$ depending on which fixed point the parity is applied.

The simplest field field is a 5d scalar $\phi(x, y)$ which transforms as

\[
\phi(x, y) = P_5 \phi(x, y) = P P_3 \phi(x, y) = P_0 \phi(x, -y), \\
\phi(x, \pi R/2 + y) = P_{5} \phi(x, \pi R/2 + y) = P_{\pi R/2} P_5 \phi(x, \pi R/2 + y) = P_{\pi R/2} \phi(x, \pi R/2 - y),
\]

17
where $0, \pi R/2$ are the fixed branes. After compactification, the 5d scalar becomes a 4d scalar.

One can also have vector fields $A_M(x, y)$ where $M = 0, 1, 2, 3, 5$. The vector transforms as

$$A_M(x, y) = P_0 P_5 A_M(x, y) \rightarrow P_0 P_5 A_\mu(x, y) = P_0 A_\mu(x, -y),$$

$$\rightarrow P_0 P_5 A_5(x, y) = -P_0 A_5(x, -y),$$

$$A_M(x, \pi R/2 + y) = P_{\pi R/2} P_5 A_M(x, \pi R/2 + y) \rightarrow P_{\pi R/2} P_5 A_\mu(x, \pi R/2 - y),$$

$$\rightarrow P_{\pi R/2} A_5(x, \pi R/2 + y) = -P_{\pi R/2} A_5(x, \pi R/2 - y),$$

where the 5th component of the 5d vector field obtains an extra minus sign. After compactification the 5d vector decomposes into a 4d vector and a 4d scalar (the fifth component).

The final representation is a 5d spinor $\Psi(x, y)$. For 5d spinors one has to enlarge the Clifford algebra. We can use the 4d Dirac matrices in the Weyl basis

$$\gamma^0 = \begin{pmatrix} 0 & I_2 \\ I_2 & 0 \end{pmatrix}, \quad \gamma^i = \begin{pmatrix} 0 & \sigma^i \\ -\sigma^i & 0 \end{pmatrix}, \quad \gamma^5 = \begin{pmatrix} -I_2 & 0 \\ 0 & I_2 \end{pmatrix},$$

where the $\gamma^5$ is the usual 4d one that is related to chirality. Note that one can choose these as gamma matrices since they fulfill

$$\{\gamma^M, \gamma^N\} = 2\eta^{MN}\mathbb{I}_4.$$  \hspace{1cm} (41)

The 5d spinor has 4 components which can be written in 4d terms as a Dirac fermion

$$\Psi(x, y) = \begin{pmatrix} \psi_R \\ \psi_L \end{pmatrix},$$

where each $\psi_{L,R}$ is a Weyl fermion. The dynamical term $i\bar{\Psi} \gamma^M \partial_M \Psi$ mixes both $\psi_{L,R}$ in any basis, so in 5d the Dirac fermion is irreducible, i.e. a 5d fermion is a pair $\psi_{L,R}$ of Weyl fermions. The parity $P_5$ operator for fermions involves a gamma matrix so

$$\Psi(x, y) = P_0 P_5 \Psi(x, y) = P_0 \gamma^5 \Psi(x, -y) \rightarrow -P_0 \psi_R(x, -y),$$

$$\Psi(x, \pi R/2 + y) = P_{\pi R/2} P_5 \Psi(x, \pi R/2 + y)$$

$$\rightarrow P_{\pi R/2} \gamma^5 \Psi(x, \pi R/2 - y) \rightarrow -P_{\pi R/2} \psi_R(x, \pi R/2 - y),$$

$$P_{\pi R/2} \psi_L(x, \pi R/2 - y).$$

After compactification, the 5d fermion decomposes into a $L, R$ 4d Weyl fermion pair.

B  $SO(3)$ gauge theory

The $SO(3)$ group is the group of $3 \times 3$ orthogonal matrices with determinant of one. It has order 3, rank 1, and its generators are

$$T_1 = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}, \quad T_2 = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 & -i & 0 \\ i & 0 & -i \\ 0 & i & 0 \end{pmatrix}, \quad T_3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -1 \end{pmatrix},$$

(44)
where an element of the group can be written as
\[ g = e^{i(\alpha T_1 + \beta T_2 + \gamma T_3)}. \] (45)

Most fields \( \Phi \) in our model will be in the adjoint representation \( \Phi \sim (3) \). One can write the 3 components of the field as
\[ \Phi = \Phi_1 T_1 + \Phi_2 T_2 + \Phi_3 T_3, \] (46)
which transforms as
\[ \Phi \rightarrow g \Phi g^{-1}. \] (47)
However it is much easier to write them in vector form as
\[ \Phi = \begin{pmatrix} \Phi_1 \\ \Phi_2 \\ \Phi_3 \end{pmatrix}, \text{ with transformation } \Phi \rightarrow g \Phi. \] (48)

We will impose the boundary condition
\[ P = e^{i\pi T_3} = \begin{pmatrix} -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{pmatrix}, \] (49)
which breaks \( SO(3) \rightarrow SO(2) \cong U(1)', \) where the \( U(1)' \) is generated by \( T_3 \).
The triplet field transforms as
\[ \Phi \rightarrow P \Phi = \begin{pmatrix} -\Phi_1 \\ \Phi_2 \\ -\Phi_3 \end{pmatrix}, \] (50)
which separates into an \( SO(2) \) doublet or a charged pair and a neutral field. A general \( U(1)' \) gauge transformation would be
\[ e^{i\alpha(x)} T_3 = \begin{pmatrix} e^{i\alpha(x)} & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & e^{-i\alpha(x)} \end{pmatrix}, \] (51)
so that we can name the eigenstates by their charge
\[ \Phi^0 = \Phi_2, \quad \Phi^+ = \Phi_1, \quad \Phi^- = \Phi_2. \] (52)
After the breaking \( SO(3) \rightarrow U(1)' \), the field decomposes as
\[ (3) \rightarrow (0) + (1) + (-1). \] (53)
Under the \( P \) transformation, the components of the \( SO(3) \) triplet decompose are eigenstates with different eigenvalues. The neutral component have an eigenvalue \( +1 \) while the charged states have a \( -1 \) eigenvalue.
Table 3: Higgs fields located at the different branes. The \(H_{u,d}^{-}\) are the physical Higgses and are renamed as \(H_{u,d}\) (see discussion in the main text).

### C Higgs localization and masses

We assume that the physical Higgs is located in the zero brane. However we have assumed that it has a charge \(-1\) under the \(U(1)'\), but the zero brane has an unbroken \(SO(3)\). To justify this, we locate the full triplet with components \(H^{+}, H^{0}, H^{-}\) on the zero brane and further two copies in the \(\pi R/2\) brane \(H'^{-}, H'^{0}\), where the \(SO(3)\) is broken, as in table 3. As discussed below, the \(H_{u,d}^{-}\) become the physical Higgses and are renamed as \(H_{u,d}\) in the main text.

These Higgses couple to the KK modes as

\[
\mathcal{L}_Y \sim H_{u} \left[ (Q_{LK}^-)^{\dagger} u_{RKK}^0 + (Q_{LK}^0)^{\dagger} u_{RKK}^+ \right] \\
+ H_{u}^0 \left[ (Q_{LK}^0)^{\dagger} u_{RKK}^0 + (Q_{LK}^+)^{\dagger} u_{RKK}^- \right] \\
+ H'_{u} \left[ (Q_{LK}^+)^{\dagger} u_{RKK}^0 + (Q_{LK}^0)^{\dagger} u_{RKK}^- \right] \\
+ H'_{u}^0 \left[ (Q_{LK}^0)^{\dagger} u_{RKK}^0 + (d_{LK}^+)^{\dagger} Q_{RKK}^+ + (d_{LK}^-)^{\dagger} Q_{RKK}^- \right]
\]

Integrating out the KK modes would generate the mass terms from the diagram in fig. 6, which would generate the mass mixing term (with the compactification scale acting as a natural cutoff)

\[
\frac{1}{16\pi^2} M_{KK}^2 (H_{u,d}^0)^{\dagger} H_{u,d}^0
\]

where \(M_{KK}^2 \sim 1/R^2\) and we ignore the 5d Dirac masses for simplicity. Although this mass will be a factor \(\frac{1}{4\pi}\) smaller than \(M_{KK}\), it will be sufficiently large to deter either of the isoneutral Higgs doublets \(H_{u,d}^0\) or \(H'_{u,d}^0\) from developing a VEV.

On the other hand, the isocharged Higgses \(H_{u,d}^{\pm}\) (the remaining parts of the isotriplets on the zero brane) do not receive such mass contributions from radiative effects, so they will readily develop VEVs. However, as only \(\phi_{KK}\) with an isocharge +1 is assumed to gain a VEV, only the \(H_{u,d}^{-}\) can generate effective Yukawa couplings. We rename these physically relevant Higgs doublets as \(H_{u,d} \equiv H_{u,d}'\).
Figure 6: Loop diagram generating isoneutral Higgs doublet mass mixing. A similar diagram for down type Higgs doublets is obtained by changing $u \rightarrow d$.
