Summary. Congenital hypothyroidism is a condition in which the thyroid gland does not produce enough thyroid hormones. It occurs in 1:2000-4000 newborns. Common clinical features include decreased activity and increased sleep, feeding difficulty, constipation, prolonged jaundice, myxedematous facies, large fontanels (especially posterior), macroglossia, distended abdomen with umbilical hernia, and hypotonia. Slow linear growth and developmental delay are usually apparent by 4-6 months of age. Without treatment, congenital hypothyroidism leads to severe intellectual deficit and short stature. Congenital hyperthyroidism occurs when the thyroid gland produces too much of the hormone thyroxine, which can accelerate body metabolism, causing unintentional weight loss and a rapid or irregular heartbeat. Hyperthyroidism is very rare and its prevalence is unknown. Common clinical features include unintentional weight loss, tachycardia, arrhythmia, palpitations, anxiety, tremor and sweating. Here we summarize the genes involved in congenital hypo- and hyperthyroidism and the tests we use for genetic analysis. (www.actabiomedica.it)

Key words: congenital hypothyroidism, non-autoimmune hyperthyroidism, thyroxine

Congenital hypothyroidism

Congenital hypothyroidism (CH) is the most common congenital endocrine disorder. It has a prevalence of 1:2000-4000 and is more frequent in females than in males (ratio of 2:1) (1). At birth, clinical features are mild or absent, becoming apparent a few months later. The disorder is characterized by reduced physical activity, increased sleeping periods, feeding difficulties, constipation, jaundice, myxedematous face, wide fontanels, macroglossia, abdominal distention with umbilical hernia, and hypotonia. Developmental and growth delay become evident 4-6 months after birth. Without therapy, the disorder leads to intellectual disability and very short stature (1).

Congenital hypothyroidism can be caused by thyroid dysgenesis (85% of cases) or defects in thyroid hormone biosynthesis (10-15% of cases) (2). Secondary congenital hypothyroidism is caused by chronic low levels of thyroid stimulating hormone (TSH) and may be due to congenital hypopituitarism. Peripheral congenital hypothyroidism is caused by defects in the transport, metabolism and action of thyroid hormones, or peripheral resistance to thyroid hormones (3). Congenital hypothyroidism can also be syndromic.

Currently, neonatal screening mainly detects elevated levels of TSH that increase in response to the reduction in thyroid hormone. This screening identifies 90% of cases of CH. Most patients have normal development after treatment with thyroxine. Besides assay of TSH, triiodothyronine (T3) and thyroxine (T4), other diagnostic tests include thyroid scanning with radioactive iodine, thyroid echography, and assay of serum thyroglobulin. These exams can help determine the etiology of the disease and differentiate permanent and transient cases (1,4). Differential
Table 1. Genes associated with congenital hypothyroidism

| Gene  | OMIM gene | Disease | OMIM disease | Inheritance | Gene function |
|-------|-----------|---------|--------------|-------------|---------------|
| THRA  | 190120    | CHNG6   | 614450       | AD          | Nuclear hormone receptor mediator of T3 biological activity |
| NKX2-1| 600635    | CAHTP   | 610978       | AD          | Transcription factor for expression of thyroid-specific genes |
| NKX2-5| 600584    | CHNG5   | 225250       | AD          | Transcription factor for thyroid organogenesis |
| BAX8  | 67415     | CHNG2   | 218700       | AD          | Transcription factor for expression of thyroid-specific genes, maintenance of thyroid cell differentiation |
| POU1F1| 173110    | CPHD1   | 613038       | AD, AR      | Transcription factor involved in specification of lactotrope, somatotrope and thyrotrope phenotypes in developing anterior pituitary gland |
| GNAS  | 139320    | PHP1A   | 103580       | AD          | Activation of adenylate cyclase that regulates thyroid activity |

Hypothyroidism and hyperthyroidism

Nonautoimmune hyperthyroidism

Nonautoimmune hyperthyroidism or hereditary hyperthyroidism is a rare form of hyperthyroidism, characterized by excessive thyroid activity. Major symptoms are hyperactivity, anxiety, weight loss, exophthalmos and tachycardia (8). Age of onset is highly variable. Clinical diagnosis is based on observation and measurement of plasma concentrations of thyroid hormone. Differential diagnosis is based on absence of exophthalmos and presence of myxedema, anti-TSH antibodies and lymphocyte infiltration of the thyroid (9). Hyperthyroidism can be treated with drugs that inhibit thyroid activity or with ablation therapy (surgery or radioiodine) (10).

The nonautoimmune hyperthyroidism has autosomal dominant inheritance and is caused by mutations in TSHR (OMIM gene: 603373; OMIM disease: 609152, 603373) (9). Prevalence is unknown: very few families (130 patients from 22 families) and...
some sporadic cases, especially in Caucasian subjects, have been described (9,11).

Pathogenic variants may be missense, nonsense, splicing or small indels. MAGI uses an NGS panel to detect nucleotide variations in coding exons and flanking introns of $TSHR$.

**Conclusions**

We created a NGS panel to detect nucleotide variations in coding exons and flanking regions of all the genes associated with hypo- and hyperthyroidism. When one of those suspects is present we perform the analysis of all the genes present in this short article.

In order to have a high diagnostic yield, we developed a NGS test that reaches an analytical sensitivity (proportion of true positives) and an analytical specificity (proportion of true negatives) of ≥99% (coverage depth ≥10x).
