Abstract. The present paper investigates properties of quasi stable ideals and of Borel-fixed ideals in a polynomial ring $k[x_0,\ldots,x_n]$, in order to design two algorithms: the first one takes as input $n$ and an admissible Hilbert polynomial $P(z)$, and outputs the complete list of saturated quasi stable ideals in the chosen polynomial ring with the given Hilbert polynomial. The second algorithm has an extra input, the characteristic of the field $k$, and outputs the complete list of saturated Borel-fixed ideals in $k[x_0,\ldots,x_n]$ with Hilbert polynomial $P(z)$. The key tool for the proof of both algorithms is the combinatorial structure of a quasi stable ideal, in particular we use a special set of generators for the considered ideals, the Pommaret basis.

1. Introduction

In the present paper, we are interested in quasi stable monomial ideals in a polynomial ring $k[x_0,\ldots,x_n]$. These ideals have a very rich combinatorial structure (summarized in Theorem 3.4) and appear in literature under several different names: for instance, they are called Borel type ideals in [15] Section 4.2.2 or monomial ideals of nested type in [2] or weakly stable ideals [7]. We are interested in these special type of monomial ideals because among them we can find the Borel-fixed ones: these are the ideals which are stable under the action of the Borel subgroup of invertible matrices. Borel-fixedness is a property depending on the characteristic of the field $k$ (Example 7.8, (1)), while quasi stability is independent of the characteristic. Borel-fixed ideals are well-known and used in algebra and also in algebraic geometry because given an ideal $I$ and a term order, the generic initial ideal of $I$ is Borel-fixed.

Further, under the hypotheses that $k$ is infinite and has characteristic 0, in some recent papers [10, 3, 5] the properties of Borel-fixed ideals where exploited to bring on a computational and effective study of the Hilbert scheme, the scheme parameterizing flat families of saturated ideals in $k[x_0,\ldots,x_n]$ having Hilbert polynomial $P(z)$. This new direct approach led to a better insight on Hilbert schemes: see for instance [4, 12]. In these two papers a key
tool to explicitly study specific Hilbert schemes is the computation of the list of Borel-fixed ideals in \( k[x_0, \ldots, x_n] \) with a given Hilbert polynomial. Under the hypothesis that the characteristic of \( k \) is 0, this list can be obtained by the algorithm presented in [9] and later improved in [16] or by the algorithm presented in [19].

In [8], the authors generalize some of the computational techniques developed in [11, 3] to the case of quasi stable ideals. Hence, there is a missing step in order to generalize the open cover of the Hilbert scheme defined in [5] and use it on specific cases also in the case of a field \( k \) of arbitrary characteristic: the explicit computation of the complete list of saturated quasi stable ideals (and in particular of Borel-fixed ideals) in the polynomial ring \( k[x_0, \ldots, x_n] \) with a given Hilbert polynomial.

The goal of the present paper is filling this gap, designing two algorithms: they both take as an input the number of variables of the polynomial ring and an admissible Hilbert polynomial. The output for one algorithm is the complete list of saturated quasi stable ideals in the chosen polynomial ring with the target Hilbert polynomial, while the output for the other one is the complete list of saturated Borel-fixed ideals with the same features, taking in input also the characteristic of the coefficient field (Algorithms 3 and 5).

For our goal, the most useful property of a quasi stable ideal is that it has a Pommaret basis, a special set of generators which can be easily computed from its minimal monomial basis. A Pommaret basis has got many useful features (see §4) that allows us to adapt the arguments of [9] for Borel-fixed ideals in characteristic 0 to both quasi stable (§5) and Borel-fixed ideals in arbitrary characteristic (§8).

The algorithms we obtain can be easily implemented on any Computer Algebra System. We wrote a non-optimized implementation in Maple [18], that could compute the complete list of quasi stable and Borel-fixed ideals in several non-trivial cases. We briefly comment two of these computations in §9.

## 2. Notations and generalities

For every \( 0 \leq \ell < n \), we consider the variables \( x_\ell, \ldots, x_n \), ordered as \( x_\ell < \cdots < x_{n-1} < x_n \). A term is a power product \( x^\alpha = x_\ell^{\alpha_\ell} \cdots x_n^{\alpha_n} \). We denote by \( \mathbb{T}(\ell) \) the set of terms in the variables \( x_\ell, \ldots, x_n \).

We denote by \( \max(x^\alpha) \) the biggest variable that appears with non-zero exponent in \( x^\alpha \) and, analogously, \( \min(x^\alpha) \) is the smallest variable that appears with non-zero exponent in \( x^\alpha \). The degree of a term is \( \deg(x^\alpha) = \sum_{i=\ell}^{n} \alpha_i = |\alpha| \).

Let \( k \) be a field and consider the polynomial ring \( S^{(\ell,n)} := k[x_\ell, \ldots, x_n] \) with the standard graduation. We write \( S_t^{(\ell,n)} \) for the set of homogeneous polynomials of degree \( t \) in \( S^{(\ell,n)} \). Since \( S^{(\ell,n)} = \bigoplus_{t \geq 0} S_t^{(\ell,n)} \), we define
The ideals we consider in \( S^{(\ell,n)} \) are always homogeneous. If \( I \subset S^{(\ell,n)} \) is a homogeneous ideal, we write \( I_t \) for \( I \cap S_t^{(\ell,n)} \) and \( I_{\geq t} \) for \( I \cap S_{\geq t}^{(\ell,n)} \). The ideal \( I_{\geq t} \) is the truncation of \( I \) in degree \( t \).

The ideal \( J \subseteq S^{(\ell,n)} \) is monomial if it is generated by a set of terms. If \( J \) is a monomial ideal, a minimal set of terms generating it is unique and we call it the monomial basis of \( J \) and denote it by \( B J \).

If \( I \subset S^{(\ell,n)} \) is a homogeneous ideal, we define the Hilbert function of \( S^{(\ell,n)}/I \) as \( h_{S^{(\ell,n)}/I}(t) = \dim_k(S_t^{(\ell,n)}/I_t) \). If we consider a monomial ideal \( J \), observe that \( h_{S^{(\ell,n)}/J}(t) = |T(\ell)| - |J_t \cap T(\ell)| \). For every homogeneous ideal \( I \subset S^{(\ell,n)} \) there is a numerical polynomial \( P(z) \in \mathbb{Q}[z] \) such that for every \( t \gg 0 \), \( h_{S^{(\ell,n)}/J}(t) = P(t) \), which is called the Hilbert polynomial of \( I \). A polynomial is an admissible Hilbert polynomial if it is the Hilbert polynomial of some ideal.

Let \( I \) be a homogeneous ideal in \( S^{(\ell,n)} \). Consider its graded minimal free resolution

\[
0 \to E_n \to \cdots \to E_1 \to E_0 \to I \to 0,
\]

where \( E_i = \bigoplus_J S_t^{(\ell,n)}(-a_{ij}) \). The ideal \( I \) is \( m \)-regular if \( m \geq a_{ij} - i \) for every \( i, j \). The regularity of \( I \), denoted by \( \text{reg}(I) \), is the smallest \( m \) for which \( I \) is \( m \)-regular.

If \( I \) and \( J \) are homogenous ideals in \( S^{(\ell,n)} \), we define \( (I : J) \) as the ideal \( \{f \in S^{(\ell,n)} | fg \in I \forall g \in J \} \). Further, we define \( (I : J^\infty) := \bigcup_{j \geq 0} (I : J^j) \). The ideal \( I \subset S^{(\ell,n)} \) is saturated if \( I = (I : (x_1, \ldots, x_n)) \). The saturation of \( I \) is \( I^{\text{sat}} = (I : (x_1, \ldots, x_n)^\infty) \) and \( I \) is \( m \)-saturated if \( I_t = I_t^{\text{sat}} \) for every \( t \geq m \).

### 3. Quasi Stability and Stability

In the present section we introduce quasi stability and stability of a monomial ideal. Both properties do not depend on the characteristic of the field we work on. A thorough reference on this subject is [21].

As already mentioned, quasi stable ideals can be found in literature under several different names [2, 7, 15]. Here we consider the definition given in [8], which better fits our purposes.

**Definition 3.1.** [8, Definition 4.4] Let \( J \subset S^{(\ell,n)} \) be a monomial ideal.

(i) \( J \) is quasi stable if for every \( x^\alpha \in J \cap T(\ell) \), for every \( x_j > \min(x^\alpha) \), there is \( s \geq 0 \) such that \( x^s_j x^\alpha / \min(x^\alpha) \in J \).

(ii) \( J \) is stable if for every \( x^\alpha \in J \cap T(\ell) \), for every \( x_j > \min(x^\alpha) \) then \( x^\alpha / \min(x^\alpha) \in J \).

**Remark 3.2.** In order to establish if \( J \) is quasi stable or stable it is enough to check the conditions of Definition 3.1 on the terms \( x^\alpha \in B J \).

**Example 3.3.** We consider the polynomial ring \( S^{(0,2)} \) and the monomial ideal \( J = (x_1, x_2^2) \subset S^{(0,2)} \). In order to prove that \( J \) is quasi stable, we only
need to check that for some \( s \geq 0, x_s^2x_1/\min(x_1) \in J \). It is sufficient to take \( s = 2 \), hence \( J \) is quasi stable. On the other hand, \( J \) is not stable because \( x_2x_1/\min(x_1) = x_2 \notin J \).

Combining the various definitions and properties appearing in literature, we get that there are several equivalent properties characterizing quasi stable ideals.

**Theorem 3.4.** \[15\], Proposition 4.2.9,\[21\], Proposition 4.4] Let \( J \subset S(\ell,n) \) be a monomial ideal, \( P(z) \) be the Hilbert polynomial of \( J \) and \( d \) be the degree of \( P(z) \). The following conditions are equivalent:

(i) \( J \) is quasi stable;
(ii) for each term \( x^\alpha \in J \) and for all integers \( i, j, m \) such that \( \ell \leq i < j \leq n \) and \( x_i^m \) divides \( x^\alpha \), there exists \( s \geq 0 \) such that \( x_s^jx^\alpha/x_i^m \in J \);
(iii) for each term \( x^\alpha \in J \) and for all integers \( i, j \) such that \( \ell \leq i < j \leq n \), there exists \( s \geq 0 \) such that \( x_s^jx^\alpha/x_i^{\alpha_i} \in J \);
(iv) \( J : x_i^{\infty} = J : (x_n, \ldots, x_j)_{\infty}, \forall i = \ell, \ldots, n \);
(v) the variable \( x_\ell \) is not a zero divisor for \( S/J^{\sat} \) and for all \( \ell \leq j < d \) the variable \( x_{j+1} \) is not a zero divisor for \( S/(J,x_\ell,\ldots,x_j)^{\sat} \).

**Proof.** The equivalences between conditions from (i) to (v) are proved in \[15\] and \[21\]. We just show that (i) is equivalent to (ii).

Assume that (i) holds and apply it for every \( x^\alpha \) in the monomial ideal \( J \), with \( x_i = \min(x^\alpha) \) and \( t = 1 \). Then \( J \) fulfills Definition 3.1.

Conversely, assume that \( J \) is quasi stable. First, we prove that for every \( x^\alpha \) in \( J \), for every \( x_i \) dividing \( x^\alpha \), for every \( x_j > x_i \) there is \( s \) such that \( x_s^jx^\alpha/x_i \in J \). If \( x_i = \min(x^\alpha) \), by Definition 3.1 it is immediate that there is \( s \geq 0 \) such that \( x_s^jx^\alpha/x_i \in J \).

Consider then \( x_i > \min(x^\alpha) \), define \( a := \sum_{m>i} \alpha_m \) and consider the following terms, which belong to \( J \) by (i), for some \( s_t \geq 0 \):

\[
x^\alpha(0) := x^\alpha, \quad x^\alpha(t) = x_{s_t}^jx^\alpha(t-1)/\min(x^\alpha(t-1)), \quad t = 1, \ldots, a.
\]

Then \( \min(x^\alpha(a)) = x_i \), and then there is \( s \geq 0 \) such that \( x_{s+t}^jx^\alpha(a)/x_i \) belongs to \( J \). Following backwards the definition of the terms \( x^\alpha(t) \), we obtain that \( x_{\overline{s}}^jx^\alpha/x_i \in J \), where \( \overline{s} = s + \sum_i s_i \geq 0 \).

Iterating the above arguments, we obtain condition (ii) for every \( m \geq 0 \) such that \( x_m^j \) divides \( x^\alpha \). \( \square \)

4. Pommaret basis of a monomial ideal

We now recall the definition and some properties of the Pommaret basis of a monomial ideal. Several of the following definitions and properties hold in a more general setting, that is for involutive divisions. For a deeper insight in this topic, we refer to \[20\] \[21\] and the references therein. For a set of terms \( M \subset T(\ell) \), \((M)\) is the ideal generated by \( M \) in the polynomial ring \( S(\ell,n) \).
Definition 4.1. [20] Consider $x^\alpha \in \mathbb{T}(\ell)$. The Pommaret cone of $x^\alpha \in \mathbb{T}(\ell)$ is the set of terms $C_P(x^\alpha) = \{x^\alpha x^\delta | \max(x^\delta) \leq \min(x^\alpha)\}$. Let $M \subset \mathbb{T}(\ell)$ be a finite set. The Pommaret span of $M$ is

$$\langle M \rangle_P := \bigcup_{x^\alpha \in M} C_P(x^\alpha).$$

The finite set of terms $M$ is a weak Pommaret basis if $\langle M \rangle_P = (M)$ and it is a Pommaret basis if the union on the right hand side of (4.1) is disjoint.

Let $\overline{M} \supseteq M$ be a finite set in $\mathbb{T}(\ell)$ such that $\langle \overline{M} \rangle_P = (M)$. We call $\overline{M}$ a Pommaret completion of $M$. An obstruction is any element of $(M) \setminus \langle M \rangle_P$.

Remark 4.2.

(i) By definition, a (weak) Pommaret basis $M$ contains a finite number of terms. It is not true that every monomial ideal has such a basis [20, page 231, after the proof of Proposition 6.8]. For instance, the ideal $J = (x_0 x_1) \subset S^{0,1}$ does not contain a finite set of terms which is a Pommaret basis [8, Remark 4.3 i].

(ii) If $M$ is a weak Pommaret basis, it is always possible to find $M' \subseteq M$ such that $M'$ is a Pommaret basis [20, Proposition 2.8].

(iii) A Pommaret basis is unique and minimal in the following sense: if $M$ is a Pommaret basis and $M' \subset \mathbb{T}(\ell)$ is another finite set such that $(M) = \langle M' \rangle_P$ then $M \subseteq M'$ [20, Proposition 2.8, Proposition 2.11].

(iv) Observe that if $M$ is a Pommaret basis, then it contains the terms of the minimal monomial basis of $(M)$.

If $M$ is a finite set of terms and a finite Pommaret completion $\overline{M}$ exists, then it is possible to compute it algorithmically: it is enough to add to the set $M$ the obstructions of kind $x^\alpha x_i$ with $x^\alpha \in M$ and $x_i > \min(x^\alpha)$, obtaining in this way $\overline{M}$ [20, Algorithm 2].

Algorithm 1 COMPLETION(M)

| Input: $M \subset \mathbb{T}(\ell)$ finite set of terms |
| Output: $\overline{M}$ Pommaret completion of $M$ |
| 1: $\overline{M} \leftarrow M$; |
| 2: loop |
| 3: $F \leftarrow \{x^\alpha x_j : x^\alpha \in M, x_j > \min(x^\alpha), x^\alpha x_j \notin \langle \overline{M} \rangle_P\}$; |
| 4: if $F = \emptyset$ then |
| 5: return $\overline{M}$; |
| 6: else |
| 7: choose $x^\beta \in F$ such that no other term in $F$ divides it; |
| 8: $\overline{M} \leftarrow \overline{M} \cup \{x^\beta\}$; |
| 9: end if |
| 10: end loop |
If a finite completion of $M$ exists, the termination of Algorithm COMPLETION is proved in [13]. Observe that the output of Algorithm COMPLETION is in general a weak Pommaret basis, from which we can always obtain a Pommaret basis (see Remark 4.2 (iii)).

As already pointed out, it is not possible to find for every monomial ideal $J$ a finite subset of $T(\ell)$ which is its Pommaret basis. Nevertheless, quasi stable ideals are exactly those having a Pommaret basis.

**Theorem 4.3.** [17, Proposition 4.4] (Remark 2.10) Let $J$ be a monomial ideal in $S(\ell,n)$. The ideal $J$ is quasi stable if and only if $J$ has a Pommaret basis. Furthermore, the ideal $J$ is stable if and only if its minimal monomial basis is the Pommaret basis.

We now state several properties of Pommaret bases and of the ideals they generate. If no proof is given, we give a precise reference for the interested reader. If $J$ is a monomial ideal having a Pommaret basis, we denote it by $P(J)$.

**Definition 4.4.** Let $J$ be a quasi stable ideal in $S(\ell,n)$ and let $P(J)$ be its Pommaret basis. We define the following sets of monomials

$P(J)(j) := \{ x^\alpha \in P(J) | \min(x^\alpha) = j \}$;

$P(J)(j) := \{ x^\alpha / x_j^\alpha \forall x^\alpha \in P(J)(j) \}$.

**Lemma 4.5.** Let $J$ be a quasi stable ideal in $S(\ell,n)$ with Pommaret basis $P(J)$ and consider $\ell \leq j \leq n$.

(i) The ideal $J : (x_n, \ldots, x_j)^\infty$ has weak Pommaret basis

$P(J)(j) \cup \bigcup_{i=j+1}^n P(J)(i)$;

(ii) no term in the Pommaret basis of $J : (x_n, \ldots, x_j)^\infty$ is divided by $x_m$ with $m \leq j$;

(iii) if $J$ is a saturated ideal, then no term in $P(J)$ is divided by $x_\ell$.

**Proof.** It is sufficient to consider the equivalent property [iv] of Theorem 3.4 and use [21, Lemma 4.11].

**Lemma 4.6.** Let $M \subset T(\ell)$, $\ell \geq 1$, be the Pommaret basis of the ideal $(M) \subset S(\ell,n)$. Then $M$ is also the Pommaret basis for the ideal $(M) S(\ell-1,n)$.

**Proof.** We denote by $M$ the ideal generated by $M$ in $S(\ell-1,n)$. Let $x^\alpha$ be a term in $T(\ell)$, we denote by $C_P(x^\alpha)$ the Pommaret cone of $x^\alpha$ in $S(\ell,n)$ and by $C_{P_{L-1}}(x^\alpha)$ the Pommaret cone of $x^\alpha$ in $S(\ell-1,n)$. It is immediate that $C_P(x^\alpha) \subset C_{P_{L-1}}(x^\alpha)$.

We prove that for every $x^\beta \in M$, there is $x^\alpha \in M$ such that $x^\beta \in C_{P_{L-1}}(x^\alpha)$. If $\min(x^\beta) \geq x_\ell$, then $x^\beta$ is a term in $(M) \subset S(\ell,n)$, hence there is $x^\alpha \in M$ such that $x^\beta \in C_P(x^\alpha) \subset C_{P_{L-1}}(x^\alpha)$. Otherwise, we have
that $\min(x^\beta) = x_{\ell-1}$. Since no term in $M$ is divided by $x_{\ell-1}$, $x^\beta/x_{\ell-1}^\beta$ still belongs to $M$ and we are in the previous case: there is $x^\alpha \in M$ such that $x^\beta/x_{\ell-1}^\beta \in \mathcal{C}_P(x^\alpha)$ for some $x^\alpha \in M$. More precisely, we can write $x^\beta/x_{\ell-1}^\beta = x^\alpha x^\delta$ with $\max(x^\delta) \leq \min(x^\alpha)$. But then $x^\beta = x^\alpha (x^\delta x_{\ell-1}^\beta) \in \mathcal{C}_P(\alpha)\cdot \mathcal{C}_P(\beta)$.

\begin{lemma}
Let $J$ be a quasi stable ideal in $S^{(\ell,n)}$ and let $\mathcal{P}(J)$ be its Pommaret basis. Then:

(i) $x^\alpha \in J \setminus \mathcal{P}(J) \Rightarrow \frac{x^\alpha}{\min(x^\alpha)} \in J$;

(ii) $x^\alpha \notin J$ and $x_ix^\alpha \in J \Rightarrow$ either $x_i x^\alpha \in \mathcal{P}(J)$ or $x_i \geq \min(x^\alpha)$.

\end{lemma}

\begin{proof}
(i) We consider $x^\alpha \in J \setminus \mathcal{P}(J)$. Then $x^\alpha \in \mathcal{C}_P(x^\beta)$ with $x^\beta \in \mathcal{P}(J)$: there is $x^\delta$ with $|\delta| \geq 1$ and $\max(x^\delta) \leq \min(x^\beta)$ such that $x^\alpha = x^\beta \cdot x^\delta$. Hence $\min(x^\alpha) = \min(x^\beta) \cdot x^\delta$ and $x^\alpha/\min(x^\alpha) = x^\beta \cdot (x^\delta/\min(x^\delta))$ still belongs to $\mathcal{C}_P(x^\beta) \subseteq J$.

(ii) If $x_ix^\alpha \in J \setminus \mathcal{P}(J)$, then item (i) applies and we obtain $x_i \geq \min(x^\alpha)$.

\end{proof}

\begin{proposition}[21]Lemma 2.2, Lemma 2.3, Theorem 9.2, Proposition 9.6]

(i) Let $M \subseteq \mathbb{T}(\ell)$ be a finite set of terms of degree $s$. If for every $x^\alpha \in M$, for every $x_j \geq \min(x^\alpha)$, $x_j x^\alpha/\min(x^\alpha) \in M$, then $M$ is a Pommaret basis.

(ii) Let $J$ be a quasi stable ideal in $S^{(\ell,n)}$ and let $\mathcal{P}(J)$ be its Pommaret basis. Then the Castelnuovo-Mumford regularity of $J$ is $\max\{\deg(x^\beta)|x^\beta \in \mathcal{P}(J)\}$.

(iii) Let $J \subseteq S^{(\ell,n)}$ be a quasi stable ideal generated in degrees less than or equal to $s$. The ideal $J$ is $s$-regular if and only if $J_{\geq s}$ is stable.

(iv) Let $J$ be a quasi stable ideal in $S^{(\ell,n)}$ and consider $s \geq \deg(J)$. Then $J_{\geq s}$ is stable and the set of terms $J_s \cap \mathbb{T}(\ell)$ is its Pommaret basis.

We conclude this section giving a characterization of elements of the Pommaret basis of a monomial ideal which can be removed, still having a Pommaret basis.

\begin{definition}
Let $J \subseteq S^{(\ell,n)}$ be a stable monomial ideal. The term $x^\alpha \in J$ is $St$-minimal if for every $x^\beta \in J$, for every $x_j \geq \min(x^\beta)$, $x_j x^\beta/\min(x^\beta) \neq x^\alpha$.

\end{definition}

\begin{lemma}
Let $J$ be a quasi stable ideal, consider $s \geq \deg(J)$ and $x^\alpha \in J_s \cap \mathbb{T}(\ell) = \mathcal{P}(J_{\geq s})$. The ideal generated by the set $(J_s \cap \mathbb{T}(\ell)) \setminus \{x^\alpha\}$ is stable if and only if $x^\alpha$ is $St$-minimal for $J_{\geq s}$.

\end{lemma}
Proof. We denote by $M$ the set $(J_s \cap T(\ell)) \setminus \{x^\alpha\}$.

If $x^\alpha$ is St-minimal, then Proposition 4.8 (i) holds, hence $M$ is a Pommaret basis. We now prove that the ideal generated by $M$ is stable. Suppose that $(M)$ is not stable. By Theorem 4.3, we assume that there is a term $x^\beta \in M \setminus B(M)$. This means that $x^\beta = x^\alpha \cdot x^\delta$ with $x^\alpha \in B(M)$ and $|\delta| \geq 1$. In particular $|\alpha| < s$, but this is not possible since all terms in $M$ have degree $s$, and the same for the terms in $B(M)$ (see also Remark 4.2, (iv)).

If $x^\alpha$ is not St-minimal, then there is $x^\beta \in M$ and $x_j > \min(x^\beta)$ such that $x_j x^\beta / \min(x^\beta) = x^\alpha$. Observe that the latter equality means that $x_j x^\beta \in C_P(x^\alpha)$. Hence, $x_j x^\beta$ belongs to the ideal $(M)$ but does not belong to $\langle M \rangle_P$, that is $x_j x^\beta$ is an obstruction and $M$ is not a Pommaret basis.

\[\Box\]

5. Quasi stable ideals and Hilbert Polynomial

In the present section, we design an algorithm which takes as input $n$, $0 \leq \ell \leq n - 1$ and an admissible Hilbert polynomial $P(z)$ for ideals in $S^{(\ell,n)}$, and returns the list of saturated quasi stable ideals $J$ in $S^{(\ell,n)}$ having Hilbert polynomial $P(z)$. The list we obtain is independent on the characteristic of the field $k$. We follow the lines of [9, 16], where the authors work under the hypothesis that $k$ has characteristic 0. We remove the hypothesis on the characteristic, and deal with quasi stable ideals, thanks to Pommaret bases.

A crucial point in the algorithm is Gotzmann Regularity Theorem, that we now recall. For a proof, we refer to [22, Appendix B.6] and [6, Section 4.3].

**Theorem 5.1 (Gotzmann Regularity Theorem).** Let $I$ be a homogeneous ideal in $S^{(\ell,n)}$. Write the Hilbert polynomial $P(z)$ of $I$ in the unique form

\[P(z) = \left(\begin{array}{c} z + a_1 \\ a_1 \end{array}\right) + \left(\begin{array}{c} z + a_2 - 1 \\ a_2 \end{array}\right) + \cdots + \left(\begin{array}{c} z + a_r - (r - 1) \\ a_r \end{array}\right)\]

with $a_1 \geq a_2 \geq \cdots \geq a_r$. Then the saturation $I^{\text{sat}}$ of $I$ is $r$-regular.

**Remark 5.2.**

1. We can rephrase a part of the statement of Theorem 5.1 for a fixed admissible Hilbert polynomial $P(z)$, there is an integer $r$ upper bounding the regularity of every ideal $I \subset S$ having Hilbert polynomial $P(z)$. The integer $r$ only depends on $P(z)$ and is called Gotzmann number. The Gotzmann number is a sharp bound for the regularity of ideals having Hilbert polynomial $P(z)$: indeed, the regularity of the Lex-segment ideal with Hilbert polynomial $P(z)$ is $r$ [11].

2. If $P(z)$ has Gotzmann number $r$, then the Gotzmann number of the Hilbert polynomial $\Delta P(z) := P(z) - P(z - 1)$ is $\leq r$. This is a consequence of the proof of Gotzmann regularity theorem.
Given a quasi stable ideal $J \subset S[\ell,n]$, we call $x_{\ell+1}$-saturation of $J$ the ideal $(J : x_{\ell}^\infty) : x_{\ell+1}^\infty$ and denote it by $J_{x_{\ell}x_{\ell+1}}$. We say that the quasi stable ideal $J$ is $x_{\ell+1}$-saturated if $J = J_{x_{\ell}x_{\ell+1}}$.

First, we will establish a connection between properties of a quasi stable ideal $J \subset S[\ell,n]$ and its generic hyperplane section. This will give us a recursive method to compute quasi stable ideals with a given Hilbert polynomial.

Remark 5.3. In $S^{(\ell,n)}$, consider $J$ a quasi stable ideal with Hilbert polynomial $P(z)$; the term $x_\ell$ is a non-zero divisor in $S^{(\ell,n)}/J_{\text{sat}}$ (Theorem 3.4 (v)). The ideal $(J, x_\ell)/(x_\ell) \subset S^{(\ell+1,n)}$ has the same Hilbert polynomial as $(J, x_\ell) \subset S^{(\ell,n)}$. Further, $J_{\text{sat}}$ has the same Hilbert polynomial as $J$, since for $t \geq 0$, $J_{t} = J_t$. Hence, we can consider the short exact sequence

$$0 \rightarrow S^{(\ell,n)}_{J_{\text{sat}}} (t-1) \rightarrow S^{(\ell,n)}_{J_{\text{sat}}}(t) \rightarrow S^{(\ell,n)}_{(J_{\text{sat}}, x_\ell)}(t) \rightarrow 0,$$

and we obtain that the Hilbert polynomial of $(J_{\text{sat}}, x_\ell)$ is $\Delta P(z)$. This is also the Hilbert polynomial of $(J, x_\ell)$, since $(J_{\text{sat}}, x_\ell)_t = (J_{t}, x_\ell)_t = (J_t, x_\ell)_t$, for every $t \geq r$.

Further, observe that $(J, x_\ell)/(x_\ell) \subset S^{(\ell+1,n)}$ is quasi stable too and $((J, x_\ell)/(x_\ell))_{\text{sat}}$ is generated by $J_{x_{\ell}x_{\ell+1}}$ in $S^{(\ell+1,n)}$, by Theorem 3.4 (iv).

In order to compute all saturated quasi stable ideals in $S^{(\ell,n)}$ with a given Hilbert polynomial $P(z)$, we can use a recursion on the number of variables of the polynomial ring. Assume that we have a complete list $E$ of saturated quasi stable ideals in $S^{(\ell+1,n)}$ generated in degrees $\leq r$ with Hilbert polynomial $\Delta P(z)$. Then, we will construct every saturated quasi stable ideal $J$ in $S^{(\ell,n)}$ with Hilbert polynomial $P(z)$ such that $((J, x_\ell)/(x_\ell))_{\text{sat}}$ is among the ideals in the list $E$.

The following Proposition and Lemmas prove the correctness of this recursive strategy and also show how to construct a quasi stable ideal $J$ in $S^{(\ell+1,n)}$ with Hilbert polynomial $\Delta P(z)$.

Proposition 5.4. Let $J \subset S^{(\ell,n)}$ be a saturated quasi stable ideal, let $P(z)$ be its Hilbert polynomial and $r$ be the Gotzmann number of $P(z)$. Consider the ideal $I := J_{x_{\ell}x_{\ell+1}}$ and define $q := \dim_k I_r - \dim_k J_r$. Then the Hilbert polynomial of $I$ is $P(z) - q$.

Proof. We prove that for every $s \geq r$, if $\dim_k I_s - \dim_k J_s = q$, then $\dim_k I_{s+1} - \dim_k J_{s+1} = q$.

We consider the set of terms in $I_s \setminus J_s$ and denote them by $x^{\beta_1}, \ldots, x^{\beta_q}$. It is immediate that $x_\ell x^{\beta_1}, \ldots, x_\ell x^{\beta_q}$ belong to $I_{s+1} \setminus J_{s+1}$: indeed, by Lemma 4.7, if the term $x^{\beta}$ does not belong to $J$, then $x_\ell x^{\beta}$ is not in $J$, because $J$ is saturated and no term in its Pommaret basis is divided by $x_\ell$ (Lemma 4.5 (iii)). Hence $\dim_k I_{s+1} - \dim_k J_{s+1} \geq q$. 

In order to prove the other inequality, we proceed by contradiction. Consider \( x^\gamma \in I_{s+1} \setminus J_{s+1} \) with \( \min(x^\gamma) \geq x_{t+1} \). Since \( I \) is the \( x_{t+1} \)-saturation of 
J, we can consider the smallest integer \( t > 0 \) such that \( x^\gamma x_{t+1} \in J \). Hence, for some \( x^\alpha \in \mathcal{P}(J) \), \( x^\gamma x_{t+1} \in C_P(x^\alpha) \). More explicitly, \( x^\gamma x_{t+1} = x^\alpha \cdot x^\delta \) with \( \max(x^\delta) \leq \min(x^\alpha) \). Observe that \( |\alpha| \leq r < s + 1 = |\gamma| \) by Proposition \ref{4.8} (ii), hence \( |\delta| \geq 1 \). Furthermore, \( \min(x^\gamma x_{t+1}^t) = x_{t+1} = \min(x^\delta) \). We can then simplify \( x_{t+1} \) and obtain \( x^\gamma x_{t+1}^t = x^\alpha \cdot (x^\delta / x_{t+1}) \in J \). But this contradicts the minimality of \( t \).

**Lemma 5.5.** Let \( J \) be a quasi stable ideal in \( S^{(\ell,n)} \), let \( P(z) \) be its Hilbert polynomial and let \( r \) be the Gotzmann number of \( P(z) \). For every \( s \geq r \), consider a \( \ell \)-minimal term \( x^\beta \in J_s \) with \( \min(x^\beta) = x_{t} \) and let \( M \subset S^{(\ell,n)} \) be the set of terms \( (J_s \cap \mathbb{T}(\ell)) \setminus \{ x^\beta \} \). Then the ideal generated by \( M \) is stable and its Hilbert polynomial is \( P(z) + 1 \).

**Proof.** First, we recall that \( J_s \cap \mathbb{T}(\ell) \) is the Pommaret basis of \( J_{\geq s} \) and the set \( M \) is the Pommaret basis for the stable monomial ideal it generates (by Lemmas \ref{4.8}, items (ii) and (iv), and \ref{4.10}).

We now show that for every \( t \geq 0 \), \( J_{s+t} \setminus (M)_{s+t} \) contains only the term \( x^\beta x_{t}^t \). We proceed by induction on \( t \). If \( t = 0 \), \( J_s \setminus (M) = J_s \setminus M = \{ x^\beta \} \) by definition of \( M \). We can assume that the thesis holds for every integer smaller than \( t > 0 \).

Any term in \( J_{s+t} \setminus (M)_{s+t} \) is a multiple of a term in \( J_{s+t-1} \setminus (M)_{s+t-1} = \{ x^\beta x_{t-1}^{t-1} \} \), by inductive hypothesis. Hence, consider \( x^\gamma = x^\beta x_{t-1}^{t-1} x_j \) with \( x_j > x_t \). Since \( \min(x^\beta) = x_{t} \), there is \( x^\alpha \in J_s \), \( x^\alpha \neq x^\beta \), such that \( x^\gamma \) belongs to \( C_P(x^\alpha) \). But \( x^\alpha \) also belongs to \( M \), hence \( x^\gamma \) belongs to \( (M) \) too.

Suppose now that \( x^\beta x_{t}^t \in M \). Since \( M = J_s \setminus \{ x^\beta \} \) is a Pommaret basis for \( (M) \), there is a term \( x^\alpha \in J_s \), \( x^\alpha \neq x^\beta \), such that \( x^\beta x_{t}^t \in C_P(x^\alpha) \). Since \( x_t = \min(x^\beta x_{t}^t) \) and \( t > 0 \), then \( x^\beta x_{t}^{t-1} \) belongs to \( C_P(x^\alpha) \subset (M) \) too, against the inductive hypothesis. Hence, \( J_{s+t} \setminus (M)_{s+t} = \{ x^\beta x_{t}^t \} \).

**Lemma 5.6.** Let \( I \) and \( J \) be quasi stable ideals in \( S^{(\ell,n)} \), let \( P_1(z) \) be the Hilbert polynomial of \( I \) and \( P_2(z) \) be the Hilbert polynomial of \( J \). If, for every \( s \gg 0 \), we have \( I_s \subset J_s \) and \( P_1(z) = P_2(z) + a \), with \( a \in \mathbb{N} \), then \( I \) and \( J \) have the same \( x_{t+1} \)-saturation and for every \( s \gg 0 \) there is a term \( x^\beta \in J_s \setminus I_s \), with \( \min(x^\beta) = x_{t} \), which is \( \ell \)-minimal.

**Proof.** Let \( s \geq \max\{ \text{reg}(I), \text{reg}(J) \} \). If \( a = 1 \), let \( x^\alpha \) be the unique term in \( J_s \setminus I_s \). Then, both \( x^\alpha x_{t} \) and \( x^\alpha x_{t+1} \) belong to \( J_{s+1} \). Since \( J \) and \( I \) are quasi stable and \( s \geq \max\{ \text{reg}(I), \text{reg}(J) \} \), by Lemma \ref{4.8}, \( J_s \cap \mathbb{T}(\ell) \) is the Pommaret basis of \( J_{\geq s} \) and \( I_s \cap \mathbb{T}(\ell) \) is the Pommaret basis of \( I_{\geq s} \). Suppose that for some \( t > 0 \), \( x^\alpha x_{t}^t \in I_{s+t} \); then \( x^\alpha x_{t}^t \in C_P(x^\beta) \) for some \( x^\beta \) in \( I_s \subset J_s \). This is not possible, since \( x^\alpha \in J_s \), hence \( x^\alpha x_{t}^t \) is not in the involutive cone of any other term in \( J_s \).
Since for every \( t > 0 \), \( J_{s+t} \setminus I_{s+t} \) contains the unique term \( x^\alpha x_\ell^t, x^\alpha x_{\ell+1} \) belongs to \( I_{s+1} \). This is enough to say that \( I \) and \( J \) have the same \( x_\ell+1 \)-saturation, by Lemma 4.5. Further, \( I_s \cap T(\ell) = (J_s \cap T(\ell)) \setminus \{x^\alpha\} \) and this implies that \( x^\alpha \) is St-minimal, by Lemma 4.10. Finally, every term \( x^\beta \in \mathcal{C}_P(x^\alpha), |\beta| \geq s \), does not belong to \( I_s \geq s \), because its Pommaret basis is \( I_s = J_s \setminus \{x^\alpha\} \). If \( \min(x^\alpha) = x_j > x_\ell \), then the number of terms in \( \mathcal{C}_P(x^\alpha) \) of any fixed degree \( \geq s \) would be strictly bigger than 1, in contradiction with \( a = 1 \). Finally, for every \( t > 0 \), the term \( x^\alpha x_\ell^t \) is St-minimal for \( J_{s+t} \).

If \( a > 1 \), the thesis follows by induction and by applying Proposition 5.5; indeed, observe that among the terms in the set \( J_s \setminus I_s \), one is St-minimal, otherwise \( I_s \) would not be stable (Lemma 4.10) and its minimal variable must be \( x_\ell \), otherwise \( P_1(z) - P_2(z) \) would not be constant. \( \square \)

6. **AN ALGORITHM TO COMPUTE QUASI STABLE IDEALS WITH A GIVEN HILBERT POLYNOMIAL**

We now present the algorithm that computes the complete list of quasi stable monomial ideals \( J \subset S(\ell,n) \) with a given Hilbert polynomial \( P(z) \).

We define two auxiliary functions that are recalled in the two main routines:

- **GotzmannNumber**\((P(z))\): takes as input the admissible Hilbert polynomial \( P(z) \) and returns its Gotzmann number;
- **StMinimal**\((J, \ell, n, r)\): takes as input the quasi stable ideal \( J \subset S(\ell,n) \) and the integer \( r \) and returns the St-minimal elements of \( J_r \) with minimal variable \( x_\ell \).

**Algorithm 2 Remove**\((I, \ell, n, r, q)\)

| Input:  | \( I \) set of monomials generating a quasi stable ideal; |
|---------|-----------------------------------------------------------|
| Input:  | \( \ell \) first index of the variables in the polynomial ring; |
| Input:  | \( n \) least index of the variables of the polynomial ring; |
| Input:  | \( r \) upper bound on \( \text{reg}(I) \); |
| Input:  | \( q \) number of terms to remove from \( I_r \); |
| Output: | \( L \) set of the saturated quasi stable ideals \( J \) obtained by removing \( q \) St-minimal terms divided by \( x_\ell \) from \( I_r \); |

1: \( L \leftarrow \emptyset; \)
2: if \( q = 0 \) then
3: \hspace{1em} return \( L \cup I_{\text{sat}} \);\)
4: else
5: \hspace{1em} \( M \leftarrow \text{StMinimal}(I, \ell, n, r); \)
6: \hspace{1em} for all \( x^\alpha \in M \) do
7: \hspace{2em} \( L \leftarrow L \cup \text{Remove}(I_r \setminus \{x^\alpha\}, \ell, n, r, q - 1); \)
8: \hspace{1em} end for
9: end if
10: return \( L \);
Algorithm 3 QuasiStable($\ell, n, P(z), r$)

**Input:** $\ell$ first index of the variables in the polynomial ring;
**Input:** $n$ least index of the variables of the polynomial ring;
**Input:** $P(z)$ admissible Hilbert polynomial;
**Input:** $r$ Gotzmann number of $P(z)$, can be computed by $\text{GotzmannNumber}(P(z))$;

**Output:** $F$ set of the saturated quasi stable ideals $J$ in the polynomial ring $S^{(\ell,n)}$ having Hilbert polynomial $P(z)$;

1: if $P(z) = 0$ then
2: return $\{(1)\}$;
3: else
4: $E \leftarrow \text{QuasiStable}(n, \ell + 1, \Delta P(z), r)$;
5: $F \leftarrow \emptyset$;
6: for all $J \in E$ do
7: $I \leftarrow J \cdot k[x_\ell, \ldots, x_n]$;
8: $q \leftarrow P(r) - (n - \ell + r) + \dim_k I_r$;
9: if $q \geq 0$ then
10: $F \leftarrow F \cup \text{Remove}(I, \ell, n, r, q)$;
11: end if
12: end for
13: end if
14: return $F$;

**Theorem 6.1.** Algorithm $\text{Remove}(I, \ell, n, r, q)$ returns the set of all quasi stable ideals in the polynomial ring $S^{(\ell,n)}$ having the same $x_{\ell+1}$-saturation as $I$ and having as Hilbert polynomial $P_1(z) + q$, where $P_1(z)$ is the Hilbert polynomial of $I$.

**Proof.** The correctness of Algorithm $\text{Remove}$ comes from Lemmas 5.5 and 5.6. $\square$

**Theorem 6.2.** Algorithm $\text{QuasiStable}(\ell, n, P(z), r)$ returns the set of all quasi stable saturated ideals in the polynomial ring $S^{(\ell,n)}$ with Hilbert polynomial $P(z)$.

**Proof.** We prove correctness of Algorithm $\text{QuasiStable}$ by induction on $\Delta^m P(z)$.

If $P(z) = 0$, then the ideal $(1)$ is the only saturated quasi stable ideal in $S^{(\ell,n)}$, hence Algorithm $\text{QuasiStable}$ returns the correct set (line 2).

Assume now that $P(z) \neq 0$ and that Algorithm $\text{QuasiStable}$ returns the correct set for $\Delta P(z)$. Then, the recursive call at line 4 returns the complete list of the $x_{\ell+1}$-saturations of the ideals we look for, as observed in Remark 5.3. Then, the correctness of Algorithm $\text{QuasiStable}$ follow from Proposition 5.4 and the correctness of Algorithm $\text{QuasiStable}$. $\square$
7. Borel-fixed ideals

In the present section, we will recall the definition and properties of Borel-fixed ideals. These ideals are interesting by themselves, since they have a rich combinatorial structure, but also they are used to investigate properties of other polynomial ideals. Indeed, if $k$ is infinite, it is possible to compute the generic initial ideal of a polynomial ideal in $S^{(\ell,n)}$. The generic initial ideal is Borel-fixed and it is used to investigate properties of the starting ideal \[14\]. If $\text{char}(k) = 0$, it is quite simple to deal with a Borel-fixed ideal, while if $\text{char}(k) > 0$, the combinatorial structure of a Borel-fixed ideal is more entangled. However, we will be able to handle it using results of the previous sections.

Definition 7.1. Let $\text{GL}(n - \ell + 1, k)$ be the general linear group, that is the group of invertible $(n - \ell + 1) \times (n - \ell + 1)$-matrices with entries in $k$. Every $g = (g_{ij}) \in \text{GL}(n - \ell + 1, k)$ induces a linear automorphism $g : S^{(\ell,n)} \to S^{(\ell,n)}$,
\[
f(x_\ell, \ldots, x_n) \mapsto f(\sum_{i=\ell}^n g_{i\ell} x_i, \ldots, \sum_{i=\ell}^n g_{in} x_i)
\]
We call such an automorphism of $S^{(\ell,n)}$ a linear automorphism. For every ideal $I \subseteq S^{(\ell,n)}$, we write $g(I)$ for $(g(f(x_\ell, \ldots, x_n)) | \forall f \in I)$.

We denote by $B$ the Borel subgroup of $\text{GL}(n - \ell + 1, k)$ consisting of lower triangular matrices.

Definition 7.2. Let $I \subset S^{(\ell,n)}$ be a homogeneous ideal. We say that $I$ is Borel-fixed if for every $g \in B$, $g(I) = I$.

Every Borel-fixed ideal is monomial \[11\] Theorem 15.23.]

Definition 7.3. Let $p$ be a prime number, $a$ and $b$ be natural numbers. We say that $a \prec_p b$ if and only if $(b^a) \not\equiv 0 \mod p$. We extend this definition for $p = 0$ posing that $a \prec_0 b$ if and only if $a \leq b$ in the usual sense.

Definition 7.4. For every $i < j$, for every $s > 0$, we define the $s$-th increasing move on the term $x^\alpha \in T(\ell)$ as
\[
e_{i,j}^+(s) (x^\alpha) = \frac{x_j^s x_i^{\alpha_i} x_{i+1}^{\alpha_i - s} \cdots x_j^{\alpha_j + s} \cdots x_n^{\alpha_n}}{x_i^s}
\]
We say that the increasing move $e_{i,j}^+(s)$ on the term $x^\alpha$ is $p$-admissible if $e_{i,j}^+(s)(x^\alpha) \in T(\ell)$ and $s \prec_p \alpha_i$.

Definition 7.5. For a fixed prime $p$, we define the following relation on the terms of $T(\ell)$: $x^\alpha \prec_p x^\beta$ if and only if there is a $p$-admissible increasing move $e_{i,j}^+(s)$ such that $e_{i,j}^+(s)(x^\alpha) = x^\beta$. The transitive closure of this relation gives a partial order on the set of monomials of any fixed degree, that we will keep on denoting by $\prec_p$. 
Theorem 7.6. [1] Theorem 15.23] Let \( \text{char}(k) = p \geq 0 \) and \( J \subset S^{(\ell,n)} \) be a monomial ideal. \( J \) is Borel-fixed if and only if for every \( x^\alpha \in J \), if \( x^\alpha \prec_p x^\beta \), then \( x^\beta \in J \).

Remark 7.7.

(1) Observe that it is sufficient to check the condition of Theorem 7.6 on \( B_J \) in order to establish that \( J \) is Borel-fixed. Indeed, assume that the condition holds for every \( x^\alpha \in B_J \) and consider \( x^\beta \in J \setminus B_J \). We write \( x^\beta \) as \( x^\beta = x^\alpha \cdot x^\gamma, x^\alpha \in B_J \). Consider \( i \) such that \( \beta_i > 0, j > i \) and \( s \prec_p \beta_i \). Observe that \( s \leq \beta_i = \alpha_i + \gamma_i \). If \( s \leq \gamma_i \) or \( s \prec_p \alpha_i \), then \( (x^s_j x^\alpha)/x^s_i \in J \). Otherwise, we simply need to observe that

\[
\frac{x^s_j x^\alpha}{x^s_i} \cdot x^\gamma = \frac{x^s_j x^{\alpha_i}}{x^s_i} \cdot \frac{x^{s-\alpha_i}}{x^{s-\alpha_i}} x^\gamma.
\]

Since \( s \leq \beta_i = \alpha_i + \gamma_i \), \( x^s_j x^{\alpha_i} x^\gamma/x^s_i \alpha_i \) is a term, and \( \alpha_i \prec_p \alpha_i \), hence \( x^s_j x^\alpha/x^s_i \in J \).

(2) If \( p = 0 \), then a Borel-fixed ideal \( J \) is strongly stable: for every \( x^\alpha \in J \), for every \( i < j \) such that \( x_i \) divides \( x^\alpha \), then \( e_{i,j}^{+}(x^\alpha) = x_j x^\alpha/x_i \in J \). If \( J \) is strongly stable, then it is Borel-fixed, irrespective of the characteristic of the field \( k \).

In what follows, we will say that the ideal \( J \) is \( p \)-Borel meaning that the ideal \( J \) is Borel-fixed in \( S^{(\ell,n)} \), with \( \text{char}(k) = p \).

Example 7.8.

(1) Consider \( J = (x_2^{11}, x_2^{10} x_1, x_2^2 x_1^9, x_2 x_1^8) \subset S^{(0,2)} \) with \( x_2 > x_1 > x_0 \).

The ideal \( J \) is not 0-Borel: for instance the term \( x_2^2 x_1 \) belongs to \( J \), but \( e_{1,2}^{+}(x_2 x_1^9) = x_2^3 x_1^8 \) does not. The ideal \( J \) is not 5-Borel: consider the term \( x_2 x_1^{10} \), and observe that \( e_{1,2}^{+}(x_2 x_1^{10}) = x_2^5 x_1^5 \) does not belong to \( J \). The ideal \( J \) is 3-Borel: one can check that for every \( x^\alpha \in B_J \) the condition of Theorem 7.6 holds.

(2) The ideals \( J_1 = (x_3^3, x_3^2 x_2, x_3 x_1) \) and \( J_2 = (x_3^3, x_3^2 x_2, x_3^2 x_1) \) in \( S^{(0,n)} \) are Borel-fixed for every characteristic of the field \( k \), because they are strongly stable. The ideal \( J = (x_3^{5,1}, x_3^{5,1}, \ldots, x_3^{5,1}, x_3^{5,1}) \subset S^{(0,n)} \) is \( p \)-Borel, for any \( p > 0 \). [1] pag 357

Remark 7.9. Products, intersections, sums and quotients of Borel-fixed ideals are Borel-fixed. In particular, if \( J \subset S^{(\ell,n)} \) is Borel-fixed, then \( J_{\geq m} \) is Borel-fixed for every \( m \).

In the following corollary, we just observe that a \( p \)-Borel ideal is quasi stable, hence the Pommaret basis is a suitable set of generators to handle it.

Corollary 7.10. Let \( J \) be a Borel-fixed ideal in \( S^{(\ell,n)} \), with \( \text{char}(k) = p \geq 0 \).

Then \( J \) is quasi stable and has a finite Pommaret basis \( \mathcal{P}(J) \).
Proof. If $J$ is $p$-Borel, then it fulfills condition $[\ref{thm:main}]$ of Theorem $[\ref{thm:main}]$. □

Corollary $[\ref{cor:main}]$ cannot be reversed, as shown by the following example.

**Example 7.11.** Consider the ideal $J = (x_1, x_2^3, x_3) \subset S^{(0,3)}$. $J$ is quasi stable but is not $p$-Borel for any value of $p$.
Suppose there is $p \geq 0$ such that $J$ is $p$-Borel: in particular, $1 <_p 1$ for every $p \geq 0$, hence $(x_1/\min(x_1)) \cdot x_2$ should belong to $J$, but this is not the case.

8. AN ALGORITHM TO COMPUTE $p$-BOREL IDEALS WITH A GIVEN HILBERT POLYNOMIAL

From Algorithm $[\ref{alg:main}]$ QuasiStable presented in Section $[\ref{sec:algorithm}]$, we can obtain the Borel-fixed ideals with an assigned Hilbert polynomial for a field with characteristic $p \geq 0$: it is sufficient to run Algorithm $[\ref{alg:main}]$ and then check which of the ideals output are $p$-Borel, using Theorem $[\ref{thm:main}]$ and Remark $[\ref{rem:main}]$.
However, with a modified version of Lemma $[\ref{lem:main}]$, we can modify Algorithm $[\ref{alg:main}]$ and directly obtain the set of $p$-Borel ideal with a given Hilbert polynomial. In our tests, for a fixed Hilbert polynomial, this second way to compute $p$-Borel ideals was faster than computing the whole set of quasi stable ideals (see Example $[\ref{example:main}]$).

**Definition 8.1.** Let $J$ be a $p$-Borel ideal and consider $x_\alpha \in J$. $x_\alpha$ is $p$-minimal if there is no other term in $J$ smaller than $x_\alpha$ w.r.t $<_R,p$.

**Lemma 8.2.** Let $J$ be a $p$-Borel ideal in $S^{(\ell,n)}$, let $P(z)$ be its Hilbert polynomial and let $r$ be the Gotzmann number of $P(z)$. For every $s \geq r$, let $x_\alpha \in J_s$ be a $p$-minimal and St-minimal term in $J_s$ with $\min(x_\alpha) = x_\ell$. Let $M$ be the set of terms $(J_s \cap T(\ell)) \setminus \{x_\alpha\}$. Then $(M)$ is $p$-Borel and has Hilbert polynomial $P(z) + 1$.

Proof. The ideal $J$ is $p$-Borel, hence it is quasi stable by Corollary $[\ref{cor:main}]$. Hence, Lemma $[\ref{lem:main}]$ applies and we obtain that the ideal generated by $M = J_s \cap T(\ell) \setminus \{x_\beta\}$ is quasi stable and has Hilbert polynomial $P(z) + 1$, because the term $x_\alpha$ is St-minimal and $\min(x_\alpha) = x_\ell$. The ideal generated by $M$ is also $p$-Borel, since the term $x_\alpha$ that we remove from $J_s$ is $p$-minimal. □

**Lemma 8.3.** Let $I$ and $J$ be $p$-Borel ideals in $S^{(\ell,n)}$, let $P_1(z)$ be the Hilbert polynomial of $I$ and $P_2(z)$ be the Hilbert polynomial of $J$. If, for every $s \gg 0$, we have $I_s \subset J_s$ and $P_1(z) = P_2(z) + a$, with $a \in \mathbb{N}$, then $I$ and $J$ have the same $x_\ell+1$-saturation and for every $s \gg 0$ there is $x_\alpha \in J_s \setminus I_s$, with $\min(x_\alpha) = x_\ell$, which is St-minimal and $p$-minimal.

Proof. Consider $s \geq \max\{\reg(I), \reg(J)\}$. By Lemma $[\ref{lem:main}]$, we know that for every $s \gg 0$ there is at least one term $x_\alpha \in J_s \setminus I_s$, with $\min(x_\alpha) = x_\ell$, which is St-minimal. Suppose by contradiction that among these St-minimal terms there are no $p$-minimal terms. This is against the hypothesis that $I$ (and its truncation at $s \gg 0$) is $p$-Borel. □
In general, the set of \( p \)-minimal terms and that of St-minimal terms of a \( p \)-Borel ideal are not included one in the other, but in the hypothesis of Lemma 8.3, there is always a non-empty intersection between these two sets.

**Example 8.4.** Consider \( S^{(0,3)} \), \( \text{char}(k) = 2 \), and the monomial ideal \( J = (x_3^2, x_2^3) \) which is 2-Borel. The Hilbert polynomial is \( P(z) = 4z \), whose Gotzmann number is \( r = 6 \). According to Definitions 4.9 and 8.1, the St-minimal terms of \( J \geq r \) are \( x_1^1x_2^2, x_0^0x_3^3 \) while the 2-minimal elements of \( J \geq r \) are the terms \( x_1^1x_2^2, x_0^0x_1x_2^2 \).

Thanks to Lemma 8.2, we can simply obtain an Algorithm to compute all the saturated \( p \)-Borel ideals in \( S^{(\ell,n)} \) having Hilbert polynomial \( P(z) \), without computing the whole set of quasi stable ideals with Hilbert polynomial \( P(z) \). It is sufficient to write a modified version of Algorithms 2 and 9 using Lemma 8.2 instead of Lemma 5.5. More precisely, it is easy to write a procedure \( p\text{-MINIMAL ELEMENTS}(J, \ell, n, r, p) \) which computes the terms \( x^\alpha \) in \( J_r \) with \( \text{min}(x^\alpha) = x_\ell \) and \( x^\alpha \) both \( p \)-minimal and St-minimal for \( J \geq r \).

Then we obtain Algorithm 4 \( p\text{-REMOVE} \) using \( p\text{-MINIMAL ELEMENTS} \) instead of \( \text{STMINIMAL} \).

**Algorithm 4** \( p\text{-REMOVE}(p, I, \ell, n, r, q) \)

*Input:* \( p \) characteristic of the coefficient field;
*Input:* \( I \) set of monomials generating a \( p \)-Borel ideal;
*Input:* \( \ell \) first index of the variables in the polynomial ring;
*Input:* \( n \) least index of the variables of the polynomial ring;
*Input:* \( r \) upper bound on \( \text{reg}(I) \);
*Input:* \( q \) number of terms to remove from \( I_r \);

*Output:* \( L \) set of the saturated \( p \)-Borel ideals \( J \) obtained by removing \( q \) terms divided by \( x_\ell \) from \( I_r \);

1: \( L \leftarrow \emptyset; \)
2: if \( q = 0 \) then
3: \hspace{1em} \text{return} \( L \cup I^{\text{sat}}; \)
4: else
5: \hspace{1em} \( M \leftarrow p\text{-MINIMAL ELEMENTS}(J, \ell, n, r, p); \)
6: \hspace{1em} for all \( x^\alpha \in M \) do
7: \hspace{2em} \( L \leftarrow L \cup p\text{-REMOVE}(p, I_r \setminus \{x^\alpha\}, \ell, n, r, q - 1); \)
8: \hspace{1em} end for
9: end if
10: \text{return} \( L; \)

Finally, Algorithm 5 \( \text{BOREL}(\ell, n, P(z), r, p) \) computes the list of saturated \( p \)-Borel ideals in \( S^{(\ell,n)} \) with Hilbert polynomial \( P(z) \) in the following way: at line 111 of Algorithm 4 \( \text{QUASI STABLE} \) we call Algorithm 4 instead of Algorithm 2.
Algorithm 5 Borel($\ell, n, P(z), r, p$)

Input: $\ell$ first index of the variables in the polynomial ring;
Input: $n$ least index of the variables of the polynomial ring;
Input: $P(z)$ admissible Hilbert polynomial;
Input: $r$ Gotzmann number of $P(z)$, can be computed by 
\text{GotzmannNumber}(P(z));
Input: $p$ characteristic of the coefficient field;
Output: $F$ set of the saturated $p$-Borel ideals $J$ in the polynomial ring $S^{(\ell,n)}$ having Hilbert polynomial $P(z)$;

1: if $P(z) = 0$ then
2: return \{(1)\};
3: else
4: \hspace{1em} $E \leftarrow \text{Borel}(n, \ell + 1, \Delta P(z), r, p)$;
5: \hspace{1em} $F \leftarrow \emptyset$;
6: \hspace{1em} for all $J \in E$ do
7: \hspace{2em} $I \leftarrow J \cdot k[x_\ell, \ldots, x_n]$;
8: \hspace{2em} $q \leftarrow P(r) - (n-\ell+r) + \dim_k I_r$;
9: \hspace{2em} if $q \geq 0$ then
10: \hspace{3em} $F \leftarrow F \cup p\text{-Remove}(p, I, \ell, n, r, q)$;
11: \hspace{2em} end if
12: \hspace{1em} end for
13: \hspace{1em} end if
14: return $F$;

Observe that if we consider $p = 0$, then we obtain the set of strongly stable ideals in $S^{(\ell,n)}$ having Hilbert polynomial $P(z)$, that is we obtain exactly the same algorithm as the one presented in [9]. An improved version of the latter algorithm is presented in [16].

9. Examples

We implemented prototypes of Algorithms [2] [3] [4] [5] and also of the auxiliary functions \text{GotzmannNumber}, \text{St-Minimal}, \text{p-MinimalElements}, for Maple 16 [12]. These implementations can be largely improved, in particular for Algorithms [2] and [4] for instance following the lines of [16]. Hence, we will not list timings of computation, but we highlight that these prototypes, although non-optimal, allowed us to explicitly compute a wide range of examples of quasi stable ideals and $p$-Borel ideals with a given Hilbert polynomial.

These prototypes, the following examples and many others are available at the webpage https://sites.google.com/site/cristinabertone

From the several computations performed, we have practical evidence that in order to compute the list of $p$-Borel ideals with Hilbert polynomial $P(z)$ for a fixed $p \geq 0$, it is faster to use the Algorithm [3] \text{Borel}, which relies on Lemma [3.2] than Algorithm [6] \text{QuasiStable} and then detect $p$-Borel ideals.
Example 9.1. We consider $P(z) = 6z - 3$ whose Gotzmann number is $r = 12$ and look for $p$-Borel ideals in $S^{(0,3)}$.

First, we run QuasiStable(0, 3, $P(z)$, $r$), and we obtain 322 quasi stable saturated monomial ideals. From this list, we can detect, for every $p \geq 0$, which ideals are $p$-Borel.

If we directly compute saturated 0-Borel ideals by Algorithm Borel, we find 31 ideals. If we compute the saturated 2 and 3-Borel ideals with Hilbert polynomial $P(z)$ by using Borel, we get 35 and 34 ideals, respectively. In these three cases, the time of computation running Algorithm Borel is far lower than that of running QuasiStable(0, 3, $P(z)$, $r$): the computation of the quasi stable ideals took about 8 times the time needed for the computation of $p$-Borel ideals for $p \in \{0, 2, 3\}$.

Also in the simplest case, a constant Hilbert polynomial in $S^{(0,2)}$, for different values of the characteristic of the field, we obtain different sets of saturated $p$-Borel ideals with Hilbert polynomial $P(z)$. Remember that every 0-Borel ideal is $p$-Borel for every prime $p$ (Remark 771 [2]).

Example 9.2. We consider $S^{(0,2)} = k[x_0, x_1, x_2]$ and the Hilbert polynomial $P(z) = 14$, whose Gotzmann number is $r = 14$. We directly compute the set $p$-Borel ideals with Hilbert polynomial $P(z)$ in $S^{(0,2)}$, for $p \in \{0, 2, 3, 5, 7\}$ using Algorithm Borel.

For $p = 0$, we obtain 22 saturated 0-Borel ideals (namely, strongly stable ideals) having Hilbert polynomial $P(z)$; they are

\[
J_1 = (x_2, x_1^{14}), \quad J_2 = (x_2^3, x_2x_1^{6}, x_1^{3}), \quad J_3 = (x_2^2, x_1^7, x_2, x_1^{3}),
\]
\[
J_4 = (x_2^2, x_1^7, x_2, x_1^{3}), \quad J_5 = (x_2^2, x_1^7, x_2, x_1^{3}), \quad J_6 = (x_2, x_1^7, x_2, x_1^{3}),
\]
\[
J_7 = (x_2^2, x_1^7, x_2, x_1^{3}), \quad J_8 = (x_2^2, x_1^7, x_2, x_1^{3}), \quad J_9 = (x_2^2, x_1^7, x_2, x_1^{3}),
\]
\[
J_{10} = (x_2^2, x_1^7, x_2, x_1^{3}), \quad J_{11} = (x_2, x_1^7, x_2, x_1^{3}), \quad J_{12} = (x_2^2, x_1^7, x_2, x_1^{3}),
\]
\[
J_{13} = (x_2^2, x_1^7, x_2, x_1^{3}), \quad J_{14} = (x_2^2, x_1^7, x_2, x_1^{3}), \quad J_{15} = (x_2^2, x_1^7, x_2, x_1^{3}),
\]
\[
J_{16} = (x_2^2, x_1^7, x_2, x_1^{3}), \quad J_{17} = (x_2^2, x_1^7, x_2, x_1^{3}), \quad J_{18} = (x_2^2, x_1^7, x_2, x_1^{3}),
\]
\[
J_{19} = (x_2^2, x_1^7, x_2, x_1^{3}), \quad J_{20} = (x_2^2, x_1^7, x_2, x_1^{3}), \quad J_{21} = (x_2^2, x_1^7, x_2, x_1^{3}),
\]
\[
J_{22} = (x_2^2, x_1^7, x_2, x_1^{3}).
\]

Every one of the 0-Borel ideals with Hilbert polynomial $P(z)$ is also $p$-Borel, for every prime $p$. Hence, for the other values of $p$ considered, here we just list the saturated $p$-Borel ideals which are not strongly stable.

\[
p = 2: \quad (x_2^3, x_1^4x_2, x_1^{3}), (x_2^2, x_2^3, x_1^4, x_1^{3}), (x_2^3, x_1^4x_2, x_1^{3}), (x_2^3, x_2^3, x_1^4, x_1^{3}), (x_2^3, x_1^4x_2, x_1^{3}), (x_2^3, x_2^3, x_1^4, x_1^{3}), (x_2^3, x_1^4x_2, x_1^{3}), (x_2^3, x_2^3, x_1^4, x_1^{3}).
\]
\[
p = 3: \quad (x_2^3, x_1^4x_2, x_1^{3}), (x_2^3, x_1^4x_2, x_1^{3}), (x_2^3, x_1^4x_2, x_1^{3}), (x_2^3, x_1^4x_2, x_1^{3}), (x_2^3, x_1^4x_2, x_1^{3}), (x_2^3, x_1^4x_2, x_1^{3}), (x_2^3, x_1^4x_2, x_1^{3}), (x_2^3, x_1^4x_2, x_1^{3}).
\]
\[
p = 5: \quad (x_2^3, x_1^4x_2, x_1^{3}), (x_2^3, x_1^4x_2, x_1^{3}), (x_2^3, x_1^4x_2, x_1^{3}), (x_2^3, x_1^4x_2, x_1^{3}).
\]
\[
p = 7: \quad (x_2^3, x_1^4x_2, x_1^{3}).
\]
The author deeply thanks prof. Margherita Roggero for suggesting the topic of Borel-fixed ideals in positive characteristic and her encouragement, and prof. Werner Seiler for valuable discussions and suggestions on quasi stable ideals and Pommaret bases.
