ABSTRACT: In this paper we compare the prediction for deep inelastic scattering from N=4 SYM with the HERA experimental data. The paper conveys two results. The first is the message that N=4 SYM is able to describe the DIS data with very good accuracy ($\chi^2/d.o.f. \leq 1.5$) in the region of $Q^2 = 0.85 \div 60$ GeV$^2$ with $2/\sqrt{\lambda} = 0.7 \div 0.8$. The second is that the value of string coupling constant $g_s$ turns out to be so small that none of saturation effects will be visible in the region of accessible energies, including the maximal energy of the LHC ($W = 14$ TeV).

KEYWORDS: N=4 SYM, graviton reggeization, eikonal approach.
1. Introduction

It is well known that N=4 SYM together with AdS/CFT correspondence allows us to study theoretically the regime of the strong coupling constant \[ \alpha_s \approx 1 \]. For the first time we have a theory which leads to the main ingredients of the high energy phenomenology such as the Pomeron and the Reggeons, in the limit of strong coupling. On the other hand, N=4 SYM with small coupling leads to normal QCD like physics (see Refs. \[ \cite{2, 3} \]) with OPE and linear equations for DIS as well as the BFKL equation for the high energy amplitude.

The Pomeron which appears in N=4 SYM \[ \Phi \] has the intercept and the slope of the trajectory that are equal to

\[
\alpha_{\Phi} (0) = 2 - \frac{2}{\sqrt{\lambda}} \equiv 2 - \rho; \quad \alpha_{\Phi}' (0) = 0.
\] (1.1)

in the limit of \( \rho \ll 1 \). First, we would like to recall that N=4 SYM has a simple solution for the following set of couplings:

\[
g_s = \frac{g^2_{YM}}{4\pi} = \alpha_{YM} = \frac{\lambda}{4\pi N_c}; \quad R = \alpha_{YM}' \lambda^\frac{1}{2}; \quad g_s \ll 1; \quad \text{but} \quad \lambda \gg 1
\] (1.2)
where $R$ is the radius in $AdS_5$-metric:

$$ds^2 = \frac{R^2}{z^2} \left( dz^2 + \sum_{i=1}^{d} dx_i^2 \right) = \frac{R^2}{z^2} \left( dz^2 + dx_{\mu} dx^\mu \right) \quad (1.3)$$

with $\mu = 0, 1, 2, 3$.

One can see that at large $\lambda$ the Pomeron intercept is close to 2 and, therefore, the exchange of the Pomeron gives almost real amplitude. Indeed, the unitarity constraint in this case looks as follows

$$\text{Im} A(s, b; z, z') = |A(s, b; z, z')|^2 + O(\rho = \frac{2}{\sqrt{\lambda}}) \quad (1.4)$$

Eq. (1.4) means that the contribution of the multiparticle production is small for the strong coupling and main source of the total cross section is originated by elastic and quasi-elastic (diffractive) processes when the target (proton) remains intact. Such a picture not only contradicts the QCD expectations\cite{11, 12, 13, 14, 15, 16}, but also contradicts available experimental data.

On the other hand, the main success of N=4 SYM has been achieved in the description of the multiparticle system such as quark-qluon plasma and/or the multiparticle system at fixed temperature \cite{17, 18, 19, 20}. Therefore, we have either to find a new mechanism for multiparticle production in N=4 SYM (see an attempt in Ref.\cite{21}) or to assume that $\lambda$ is not very large (say $\rho = 0.5 \div 0.8$). It should be noticed that even at $\rho = 0.8 \lambda$ is rather large $\approx 6$.

The first goal of this paper is to find the range of $\lambda$ that can describe the deep inelastic(DIS) data from HERA. We believe that correction to Eq. (1.1) is proportional to $1/\lambda$ and $\lambda \approx 6$ could lead to a good in the description of the experimental data. It can give a sizable cross section for the multiparticle production. Such an approach will be a N=4 SYM motivated model which will be able to provide a guide for a theoretical approach to QCD in the region of strong coupling.

It was shown in Refs.\cite{4, 6, 7, 8, 9, 10} that we face the saturation phenomena in N=4 SYM at low $x$ for DIS. The physics of the saturation looks very similar to the saturation phenomena in high density QCD with one essential difference: the saturation in N=4 SYM we can theoretically describe in very simple fashion based on the eikonal formulae. This approach can be easily generalized for scattering both dense and diluted systems. Using these formulae we can learn what can happen in the region of very low photon virtualities and find parameters such as $g_s$ that govern the strong interactions.

The second goal of this paper is to find parameters of N = 4 SYM that characterize the strength of interaction in the large coupling limit from the comparison with DIS data and derive the estimates for the expected saturation effects.

N=4 SYM being conformal invariant theory has only massless particles and leads to the scattering amplitudes that fall as a power of $b$ at large values of impact parameters ($b$). This decrease results in the power-like dependance of typical impact parameters in the amplitude. In particular, for hadron-hadron scattering these typical $b \propto s^{1/3}$\cite{10, 22} which contradicts the Froissart theorem \cite{23}. We have to go
beyond of N=4 SYM and discuss the string theory, conformal limit of which is N=4 SYM, to restore the logarithmic behaviour \( b \propto \ln s \) of the typical impact parameters. The third goal of this paper is to find out how the \( b \) behaviour influences the description of the experimental data.

In the paper we compare the N=4 SYM formula for deep inelastic structure function \( F_2 \) which we derive in the next section, with the HERA data for low \( x \) region \( (x \leq 0.01) \). Since the physical meaning of the fifth coordinate \( z \) (see Eq. (1.3)) is the typical size of the colliding particles, DIS gives an unique opportunity to check the predicted behaviour on \( z \). On the other hand, it is known that the energy dependance of DIS is rich and, in particular, \( F_2 \propto x^{-\lambda} \) with \( \lambda = 0.1 \div 0.5 \) for \( Q^2 = 0.1 \div 27 GeV^2 \), respectively. Therefore, we have the set of the experimental data both for checking energy and \( z \) dependance of the scattering amplitude, especially because the experimental errors are so small that it is a challenge to describe the data in any theoretical approach (see section 3 of this paper).

The paper conveys two results. The first is the message that N=4 SYM is able to describe the DIS data with very good accuracy \( (\chi^2/d.o.f. \leq 1.5) \) in the region of \( Q^2 = 0.85 \div 60 GeV^2 \) with \( \rho = 0.7 \div 0.8 \) (see section 3). The second is that the value of \( g_s \) turns out to be so small that none of saturation effects will be visible in the region of accessible energies including the maximal energy of the LHC \( (W = 14 \ TeV) \). DIS data can be described both in conformal N=4 SYM and taking into account non-conformal corrections in \( b \) dependance.

However for description of proton-proton scattering we need corrected \( b \) dependance (see section 3). The main result of Ref. [22] that it should be the other source of the multiparticle production than N=4 SYM remains even for \( \rho = 0.7 \div 0.8 \).

2. High energy Scattering in N=4 SYM

2.1 Pomeron exchange

As has been mentioned there exists the Pomeron in N=4 SYM with the parameters of its trajectory given by Eq. (1.1). The exchange of this Pomeron leads to the following contribution to the scattering amplitude (see Fig. 1-a):

\[
\tilde{A} = \frac{g_s^2}{4\pi} \left\{ \frac{2}{\pi \rho} + i \right\} \left\{ \frac{(z_1 z_2 s)^{1-\rho}}{\sqrt{u(2+u)}} \ln \left( 1 + u + \sqrt{u(2+u)} \right) \right\} \exp \left( \frac{-\ln^2 \left( 1 + u + \sqrt{u(2+u)} \right)}{\rho \ln (z_1 z_2 s)} \right) \]  

\[ \ln \left( 1 + u + \sqrt{u(2+u)} \right) \]

(2.1)

where

\[
u = \frac{(z_1 - z_2)^2 + b^2}{2z_1 z_2} \quad \text{and} \quad b \text{ is the impact parameter in the scattering amplitude} \]

(2.2)

One can see that Eq. (2.1) is very similar to the expression for the exchange of the BFKL Pomeron[14] in which the sizes of the interacting dipoles are replaced by \( z_1 \) and \( z_2 \) and in which \( \Delta_{BP} = 2 - \alpha_{BP}(0) \) and the diffusion coefficient are equal. It should be recalled that Eq. (2.1) describes high energy scattering in the kinematic region where \( z_1 z_2 s \gg \lambda \gg 1 \).
2.2 Eikonal formula

Since the Pomeron intercept is larger than 1, considering the high energy scattering we cannot restrict ourselves by the exchange of one Pomeron. It is well known that in N=4 at small coupling as well as in perturbative QCD the problem to take into account all Pomeron exchanges and the Pomeron interaction is a very difficult problem that has been only partly solved in high density QCD (see Refs. [11, 12, 13, 14, 15, 16]). However, for N=4 SYM with large coupling the situation turns out to be much simpler and at small values of ρ the amplitude can be found in the eikonal approximation [6, 7, 8, 10] (see Fig. 1-b), namely,

\[ A(s, b; z_1, z_2) = i \left\{ 1 - \exp \left( i \tilde{A}(s, b; z_1, z_2) \right) \right\} \]

The total cross section that we are going to discuss is proportional to imaginary part of the amplitude and can be written in the form for virtual photon-proton scattering in the form

\[ \sigma_{\text{tot}}(\gamma^* + p) = 2 \int d^2b \int_0^\infty dz_1 dz_2 \Phi_{\gamma^*}(z_1) \Phi_{\text{proton}}(z_2) \left\{ 1 - \cos \left( N_c^2 \text{Re} \tilde{A}(s, b; z_1, z_2) \right) \exp \left( -N_c^2 \text{Im} \tilde{A}(s, b; z_1, z_2) \right) \right\} \]

Functions \( \Phi_{\gamma^*}(z_1) \) and \( \Phi_{\text{proton}}(z_2) \) describe the probability for virtual photon and proton to have the size \( z_1 \) and \( z_2 \), respectively, and we will discussed them in the next section.

2.3 \( \Phi_{\gamma^*} \) and \( \Phi_{\text{proton}} \)

At low \( x \) the DIS on the boundary can be expressed through the dipole-proton cross section

\[ \sigma_{\text{tot}}(\gamma^* p) = \int d^2r_\perp P_{\gamma^*}(r_\perp) \sigma_{\text{tot}}(\text{dipole-proton}; r_\perp; x) \]

where the probability to find a dipole with the size \( r_\perp \) \( P_{\gamma^*}(r_\perp) \) is equal to [24]

\[ P_{\gamma^*}(r_\perp) = \frac{\alpha_{\text{em}} N_c}{2\pi^2} \sum_{f=1}^{N_f} Z_f^2 \left( \zeta^2 + (1 - \zeta)^2 \right) Q_f^2 K_1^2(\bar{Q} r_\perp) \]

where \( \zeta \) is the fraction of the energy that is carried by the quark, \( Z_f \) is the fraction of the electric charge for the quark of flavour \( f \), \( \alpha_{\text{em}} \) is the electromagnetic fine constant.
To find $\Phi_{\gamma^*}$ we need to generalize the wave function of the photon ($K_0(\bar{Q}r_\perp)$) on the boundary to the wave function in the bulk. We can reconstruct this wave function using the Witten formula \[25\], namely,

$$
\Psi_{\gamma^*}(r, z) = \frac{\Gamma(\Delta)}{\pi \Gamma(\Delta - 1)} \int d^2 r' \left( \frac{z}{z^2 + (\vec{r} - \vec{r}')^2} \right)^\Delta \Psi_{\gamma^*}(r'_\perp) \quad \text{with} \quad \Delta = \frac{1}{2} \left( d \pm \sqrt{d^2 + 4m^2} \right)
$$

where $\Psi(r_\perp)$ is the wave function of the dipole inside the photon on the boundary. Using Eq. (2.6) we can find $\Phi_{\gamma^*}(z)$ as

$$
\Phi_{\gamma^*} = \frac{\alpha_{em} N_c}{2\pi^2} \sum_{i=1}^{N_f} Z_i^2 \int_0^1 d\zeta [\zeta^2 + (1 - \zeta)^2] \bar{Q}^2 \int d^2 r |\Psi_{\gamma^*}(r, z)|^2 = \left( \frac{\Gamma(\Delta)}{\pi \Gamma(\Delta - 1)} \right)^2 \times \left( \frac{z}{z^2 + (\vec{r} - \vec{r}')^2} \right)^\Delta K_1(\bar{Q}r_\perp) K_1(\bar{Q}r'_\perp) \tag{2.7}
$$

Using the formulae 3.198, 6.532(4), 6.565(4) and 6.566(2) from the Gradstein and Ryzhik Tables, Ref. [26] we can rewrite Eq. (2.7) introducing the Feynman parameter ($\xi$) and taking the integral over $r$ and the angle between $\vec{r}$ and $\vec{r}'$. It has the form

$$
\Phi_{\gamma^*} = z^4 \frac{\alpha_{em} N_c}{2} \sum_{i=1}^{N_f} Z_i^2 \int_0^1 d\xi [\xi^2 + (1 - \xi)^2] \bar{Q}^2 \int d^2 r d^2 r' \int_0^1 d\xi K_1(\bar{Q}r_\perp) K_1(\bar{Q}r'_\perp) \tag{2.8}
\times \left( \frac{2 (\xi(1 - \xi)(r^2 - r'^2) + z^2)^2 + 4r' r'' \xi^2 (1 - \xi)^2}{(\xi(1 - \xi)(r^2 - r'^2) + z^2)^{5/2} (\xi(1 - \xi)(r^2 + r'^2) + z^2)^{5/2}} \right)
$$

In Eq. (2.8) we used that for photon $m$ and $d$ in Eq. (2.6) are equal to 0 and 2, respectively.

For $\Phi_{\text{proton}}$ we use the expression that has been suggested in Ref. [22], namely,

$$
\Phi_{\text{proton}} = \int d^2 r \prod_{i=1}^{N_c} |\Psi(r_i, z)|^2 \tag{2.9}
$$

In Eq. (2.9) we assumed that a proton consists of $N_c$ colourless dipoles and each dipole interacts with other dipoles without correlation. We use Eq. (2.7) to find out function $\Psi(r_i, z)$ . In this equation $\Psi(r')$ is the wave function of the dipole inside the proton on the boundary. For simplicity and to make all calculations more transparent, we choose $\Psi(r') = K_0(\bar{Q}r')$. The value of the parameter $\bar{Q}$ can be found from the value of the electromagnetic radius of the proton ($q \approx 0.35 GeV^{-1}$).
Substituting Eq. (2.6) in Eq. (2.9) one obtains

\( \Phi_{\text{proton}}(z) = \frac{N_c}{N} \left( \frac{\Gamma(\Delta)}{\pi \Gamma(\Delta - 1)} \right)^2 \times \int d^2r' d^2r'' d^2r \ K_0(qr'_\perp) K_0(qr''_\perp) 
\times \left( \frac{z}{z^2 + (\vec{r} - \vec{r}')^2} \right)^\Delta \left( \frac{z}{z^2 + (\vec{r} - \vec{r}'')^2} \right)^\Delta \)

where \( N \) is the norm of the dipole wave function on the boundary (\( N = \pi q^2 \) for \( K_0(qr_\perp) \)).

Using that

\( \int_0^\infty J_0(kr) r dr = \frac{1}{k^2 + q^2} \)

we obtain

\( \Phi_{\text{proton}}(z) = 2^{5-2\Delta} q^2 z^{6-2\Delta} \int_0^\infty \frac{K_1^2(\Delta(t) t^{2\Delta-1} dt}{(t^2 + q^2 z^2)^2} \)

2.4 Physical observables

We deal with the DID structure function \( F_2 \) which can be written in the form

\( F_2(Q^2; x) = \frac{Q^2}{4\pi^2 \alpha_{em}} \sigma_{tot}(\gamma^* + p; \text{Eq. (2.3)}) \) (2.13)

For proton-proton collision we will use the total cross section written as

\( \sigma_{tot}(p + p) = \int_0^\infty dz_1 dz_2 \Phi_{\text{proton}}(z_1) \Phi_{\text{proton}}(z_2) 
\times 2 \int d^2b \left\{ 1 - \cos \left( N_c^2 \text{Re} \tilde{A}(s, b; z_1, z_2) \right) \right. 
\exp \left( -N_c^2 \text{Im} \tilde{A}(s, b; z_1, z_2) \right) \left\} \right. \)

with \( \Phi_{\text{proton}}(z) \) given by Eq. (2.12). However Eq. (2.1) describes the scattering amplitude only in the region of high energies. For DIS we select only data with \( x \leq 0.02 \) and we use for fitting the following expression:

\( F_2(Q^2; x) = F_2(Q^2; x; \text{Eq. (2.13)}) + F_2^{\text{in}}(Q^2) \) (2.15)

where \( F_2^{\text{in}}(Q^2) \) is a DIS structure function at \( x_0 = 0.02 \) and it was considered as a fitting parameter at any value of \( Q \).
For proton-proton interaction we described the data at \( W = \sqrt{s} \geq 20 \text{GeV} \) and add a constant \( \sigma_0 \) to Eq. (2.14).

Eq. (2.3) which is written in N=4 SYM, has power - like decrease at large values of the impact parameter \( (b) \). On the other hand for not very small \( \rho \) the conformal symmetry of N=4 SYM is broken and we need to consider the string theory for which N=4 SYM is a conformal limit at small \( \rho \). In the string theory the hadron spectrum has the lightest hadron with the mass \( m_{\text{glueball}} = \sqrt{\rho/\alpha'} \) which leads to the exponential falldown of the amplitude \( \tilde{A}(s, b; z_1, z_2) \) at large \( b \): \( \tilde{A}(s, b; z_1, z_2) \xrightarrow{b \gg m_{\text{glueball}}} \exp\left(-m_{\text{glueball}} b\right) \). We rewrite Eq. (2.3) in the form

\[
\tilde{A}(s, b; z_1, z_2) = \tilde{A}(s, b; z_1, z_2| \text{Eq. (2.1)}) e^{-m_{\text{glueball}} b} \tag{2.16}
\]
to take into account the mass spectrum of the string theory. The final answer for the amplitude in this case is Eq. (2.3) in which \( \tilde{A} \) is replaced by \( \hat{A} \), \( (\hat{A} \to \tilde{A}) \).

In this paper we check also our description of the DIS data with the experimental data on the total cross section for proton-proton scattering. For this observable we use the following expression:

\[
\sigma_{\text{proton - proton}}(s) = \sigma_{\text{proton-proton}}(\text{Eq. (2.14)}) + \sigma_0(s) \quad \text{with} \quad \sigma_0(s) = \sigma_{01} + \frac{\sigma_{02}}{\sqrt{s}} \tag{2.17}
\]
The contribution \( \propto 1/\sqrt{s} \) corresponds to the contribution of the secondary Regge poles. \( \sigma_0(s) \) is related to the mechanism of the strong interaction that cannot be described by N=4 SYM or to unknown corrections to this theory \( \propto 1/\lambda \).

3. Comparison with the experimental data

Using the formulae of the previous section we compare the value of \( F_2(Q^2; x) \) with the HERA experimental data in the region of low \( x \) ( \( x \leq 0.02 \)). As has been mentioned our main goal is to obtain two parameters of the N=4 SYM: \( \rho \) and \( g_s \). For each chosen value of \( Q^2 \) we introduce one more phenomenological parameter: the value of \( F_2(Q^2) \). It should be mentioned that the value of \( \Delta \) in Eq. (2.6) for the proton as well as the value of \( q \) have to be found from the fit, but we have to recall that the value of \( q \) characterizes the typical scale of the non-perturbative wave function of the proton and can be extracted from the electromagnetic radius of the proton.

As we have mentioned the main qualitative experimental observation is that \( F_2 \propto (1/x)^{\lambda(Q^2)} \) and the power \( \lambda(Q^2) \) depends on \( Q^2 \) changing from \( \lambda \approx 0.1 \div 0.2 \) at low \( Q^2 \leq 1 \text{GeV}^2 \) to \( \lambda \approx 0.4 \) at high \( Q^2 > 50 \text{GeV}^2 \) (see Fig. 2).

| Solution | \( \rho \)        | \( g \)        | \( \Delta \) | \( \chi^2/\text{d.o.f.} \) |
|----------|------------------|----------------|-------------|----------------------------|
| I        | 0.701 ± 0.004    | 0.004 ± 0.001  | 2           | 1.42                       |
| II       | 0.75 ± 0.007     | 4.019 ± 0.061  | 2           | 1.22                       |

Table 1: Fitting parameters for solution I (see Eq. (2.1)) and solution II (see Eq. (2.16)).
At first sight we cannot reproduce such a behaviour since the exchange of the Pomeron generates only one power $\lambda = 1 - \rho$. The only way out is to include the Pomeron re-scattering which could lead to the amplitude with the effective power that depends on $Q$. To our surprise we fitted the HERA data with small value of $g$ which turns out to be so small that in the accessible region of energies including the LHC highest energy the Pomeron re-scattering does not contribute and only the exchange of the one Pomeron determines the amplitude. The restoration of the unitarity constraint will occur at ultra high energy.

The quality of description one can see from Fig. 3 where the new HERA data[27] are plotted at eight values of $Q^2$ as function of $x$. The message is clear: the $z$ and $\ln s$ dependence in Eq. (2.1) reproduces the change in $\lambda$ as function of $Q$ shown in Fig. 2.

The fit to the experimental data was made in two different cases: the first one (solution I) corresponds to Eq. (2.3) with the amplitude $\tilde{A}$ determined by Eq. (2.1); and the second takes into account Eq. (2.16) which restricts the integral over $b$ (solution II). The parameters that we obtain are listed in Table 1. Solution I gives small value of $g = N_c^2 g_s = 0.04$ while solution II leads to rather large $g = N_c^2 g_s = 4$. They have very close $\chi^2/d.o.f. \approx 1.5$ and describe the data equally well (see Fig. 4). However both solutions cannot describe the data at lower $Q$ (see Fig. 4-c and Fig. 4-d). From the fit we also determine the function $F_2^{\text{in}}$ in Eq. (2.15) (see Fig. 5).

It turns out that for both solutions the amplitude $A$ is small (see Fig. 3 that illustrated this fact). In this figure one sees that the amplitude $\tilde{A}$ for the solution II reaches the value of about 0.5 but in spite the fact that this value does not look very small Eq. (2.3) gives the value of the amplitude which is very close to $\text{Im} \tilde{A}$. For the solution I the value of $g$ is so small that it leads to a very small $\tilde{A}$. Therefore, the lesson which we obtain from this estimates is very simple: the data for DIS can be described in N=4 SYM but the non-linear (shadowing) corrections turns out to be very small. In other words the saturation effects which are in N=4 SYM are very similar to the one in QCD[4, 5, 6, 7, 8, 10], will be sizeable only at ultra high energy, higher than the LHC maximum energy ($W = 14 TeV$).

These two solutions we check against the experimental data for the total cross section of proton-proton interactions. The comparison with the experimental data is shown in Fig. 7.
4. Conclusions

As has been mentioned comparing the N=4 SYM prediction with the experimental data we obtain two surprising results. First, the N=4 SYM formula gives a good description of the DOIS structure function in wide range of $Q^2$ ($Q^2 = 0.85 \div 60\, GeV^2$ and $x \leq 0.01$). The surprise stems from the fact that Eq. (2.1) leads to power-loke dependence on $x$ ($F_2 \propto (1/x)^{1-\rho}$) and this power does not depend on $Q$. Comparing
this formula with Fig. 2 one can conclude that dependence of $z$ of Eq. (2.1) as well as on $\ln s$ simulates the effective power dependance on $Q$.

The second surprise is the smallness of $g_s$ that generates a very small shadowing corrections which we can neglect even at the highest accessible energy: $W = 14 \text{ TeV}$. $\rho = 0.7 \div 0.75$ means that the intercept of the Pomeron is rather small $\Delta p \approx 0.3 \div 0.35$. We used to consider such a small intercept to be typical for the weak coupling limit (for the BFKL Pomeron). On the other hand, in small coupling limit we expect a strong shadowing correction induced by the Pomeron interactions (see Refs. [11, 12, 15, 16]). Recalling that $\rho = 0.7 \div 0.75$ corresponds to $\lambda \approx 7 \div 8$ we could expect that the corrections of the order of $1/\lambda^2$ will be small. In this case we expect the small shadowing corrections with our fitted small value of $g_s$. Therefore, we have a dilemma: either the corrections of the order of $1/\lambda^2$ are large or the shadowing phenomenon is negligibly small.

The influence of the corrected $b$ dependence was expected but the fact that even with corrected $b$ dependence we have still small shadowing corrections was not expected.

In general we believe this analysis of the experimental data in the framework of N=4 SYM theory gives the useful information on the possible scenario what is going on in strong coupling limit at high energy. The picture that arises from this analysis is in clear contradiction from the expectation of the high density QCD and because of this it could lead to a better understanding the matching between soft (large coupling) and hard (small coupling) processes in QCD.
Acknowledgements

We thank Boris Kopeliovich and Chung-I Tan for fruitful discussions on the subject of this paper. Chung-I Tan was the first who mentioned to E.L. in private discussion that the description of the DIS data could lead to a very small $g_s$. Actually this remark was the main impetus for this paper.
