Lipoxin $A_4$ Attenuates Constitutive and TGF-$\beta$1-Dependent Profibrotic Activity in Human Lung Myofibroblasts

Katy M. Roach,* Carol A. Feghali-Bostwick,† Yassine Amrani,* and Peter Bradding* 

Idiopathic pulmonary fibrosis (IPF) is a common, progressive, and invariably lethal lung disease with no effective therapy. The key cell driving the development of fibrosis is the myofibroblast. Lipoxin $A_4$ (LXA$_4$) is an anti-inflammatory lipid, important in the resolution of inflammation, and it has potential antifibrotic activity. However, the effects of LXA$_4$ on primary human lung myofibroblasts (HLMFs) have not previously been investigated. Therefore, the aim of this study was to examine the effects of LXA$_4$ on TGF-$\beta$1–dependent responses in IPF- and nonfibrotic control (NFC)–derived HLMFs. HLMFs were isolated from IPF and NFC patients and grown in vitro. The effects of LXA$_4$ on HLMF proliferation, collagen secretion, $\alpha$-smooth muscle actin (αSMA) expression, and Smad2/3 activation were examined constitutively and following TGF-$\beta$1 stimulation. The LXA$_4$ receptor (ALXR) was expressed in both NFC- and IPF-derived HLMFs. LXA$_4$ ($10^{-10}$ and $10^{-8}$ mol) reduced constitutive αSMA expression, actin stress fiber formation, contraction, and nuclear Smad2/3, indicating regression from a myofibroblast to fibroblast phenotype. LXA$_4$ also significantly inhibited FBS-dependent proliferation and TGF-$\beta$1–dependent collagen secretion, αSMA expression, and Smad2/3 nuclear translocation in IPF-derived HLMFs. LXA$_4$ did not inhibit Smad2/3 phosphorylation. In summary, LXA$_4$ attenuated profibrotic HLMF activity and promoted HLMF regression to a quiescent fibroblast phenotype.

LXA$_4$ or its stable analogs delivered by aerosol may offer a novel approach to the treatment of IPF. The Journal of Immunology, 2015, 195: 000–000.
inhibits epithelial mesenchymal transition in renal epithelial cells (23), whereas knockout of the 12/15-LOX pathway prevents experimental dermal fibrosis (24). With respect to lung fibrosis, LXA₄ inhibited connective tissue growth factor-dependent proliferation of a human lung fibroblast cell line (25), whereas a stable epi-LXA₄ analog reduced bleomycin-induced pulmonary fibrosis in mice (26).

The effects of LXA₄ on the function of healthy and IPF-derived primary human lung myofibroblast (HLMF) function are unknown. We hypothesized that LXA₄ inhibits constitutive HLMF profibrotic responses and TGF-β₁-driven profibrotic activity through the Smad signaling pathway. We therefore investigated the effects of LXA₄ on constitutive and TGF-β₁-dependent HLMF Smad 2/3 activity, gene transcription, and profibrotic HLMF processes such as contraction, collagen secretion, proliferation, and differentiation.

Materials and Methods

Human lung myofibroblast isolation, characterization, and culture

Nonfibrotic control (NFC) HLMFs were derived from healthy areas of lung from patients undergoing lung resection for carcinoma at Glenfield Hospital, Leicester, U.K. No morphological evidence of disease was found in the tissue samples used for HLMF isolation. IPF HLMFs were derived from patients undergoing lung transplant at the University of Pittsburgh Medical Center and were shown to have usual interstitial pneumonia on histological examination. Myofibroblasts were grown, cultured, and characterized as previously described (27). All NFC patients gave informed written consent, and the study was approved by the National Research Ethics Service (references 07/MRE08/42 and 10/H0102/12). Written informed consent was also obtained from all IPF subjects, with the protocol approved by the University of Pittsburgh Institutional Review Board.

All cultures demonstrated the typical elongated spindle-shaped fibroblast morphology. All cultures underwent further extensive characterization via flow cytometry and immunofluorescence. They were found to be predominately a myofibroblast-rich population (99% expressing αSMA) as described previously by us and others (15, 27–30). They expressed αSMA, CD90, fibroblast surface protein, and collagen type I. No contaminating cells were found. Immunostaining for macrophages (CD68), T cells (CD3), and progenitor cells (CD34) was negative. There was no evidence of cobblestone-shaped epithelial cells among the cultures. Results of this detailed characterization have been shown previously (27, 30).

LXA₄

LXA₄ [5(S),6(R)-Lipoxin A₄] (Cayman Chemical) was used at concentrations of 10⁻¹⁰ and 10⁻⁸ mol.

Flow cytometry

HLMFs were grown in T25 flasks and serum-starved for 24 h prior to experiments. The myofibroblasts were incubated for 24 h and either left unstimulated or stimulated with TGF-β₁ (10 ng/ml) (R&D Systems, Oxford, U.K.).

To determine the expression of the LXA₄ receptor ALXR, HLMFs were detached using 0.1% trypsin/0.1% EDTA and gated using fibroblast surface Ag Thy-1 (Merck, Hertfordshire, U.K.). Myofibroblasts were then labeled with allophycocyanin-conjugated mouse monoclonal anti–formyl-peptide receptor-like 1 (FPRL1; also known as ALXR) (R&D Systems) or allophycocyanin–conjugated isotype control IgG2b Ab (R&D Systems).

To study the inhibitory effects of LXA₄ on αSMA expression, HLMFs were incubated in the presence of serum-free medium alone or 0.1% ethanol vehicle control or LXA₄ at 10⁻¹⁰ and 10⁻⁸ mol. Cells were detached using 0.1% trypsin/0.1% EDTA, washed, then fixed, and permeabilized in 4% paraformaldehyde plus 0.1% saponin (Sigma-Aldrich, Poole, Dorset, U.K.) for 20 min on ice. Myofibroblasts were labeled with either: FITC-conjugated mouse monoclonal anti-αSMA (Sigma-Aldrich) or isotype control FITC-conjugated mouse IgG₂a; secondary Abs labeled with FITC were applied if appropriate. Analysis was performed using single-color flow cytometry on an FACSscan (BD Biosciences, Oxford, U.K.).

Immunofluorescence

HLMFs were grown on eight-well chamber slides and serum-starved for 24 h prior to the experiment. The cells were left unstimulated and incubated in the presence of 0.1% ethanol vehicle control or LXA₄ at 10⁻¹⁰ and 10⁻⁸ mol for 48 h. Cells were then immunostained as described previously (27) using FITC-conjugated mouse monoclonal anti-αSMA (F3777; 10 μg/ml, Sigma-Aldrich) and isotype control FITC-conjugated mouse IgG₂a (X0933, 10 μg/ml; DakoCytomation, Ely, U.K.). Cells were mounted with fluorescent mounting medium and coverslipped. Original images were captured on an epifluorescence microscope (Olympus BX50; Olympus UK, Southend-on-Sea, U.K.); grayscale intensity was examined using Cell F imaging software (Olympus UK). Matched exposures were used for isotype controls.

Actin stress fibers were calculated using a specialized macro on Image J (National Institutes of Health) designed by Dr. Kees Straatman, University of Leicester (15). The macro is capable of providing a quantitative, unbiased score of the number of stress fibers per individual cell by determining the fluctuations of grayscale intensity created by the αSMA staining within the stress fibers.

Collagen gel contraction assay

HLMFs were serum-starved for 24 h and then pretreated for 24 h with serum-free medium alone, 0.1% ethanol control, LXA₄ 10⁻¹⁰, or LXA₄ 10⁻⁸ mol. Cells were detached and embedded in collagen gels as described previously (31). TGF-β₁ was then added to appropriate wells to a final concentration of 10 ng/ml. Photographs were taken at 0 and 24 h. The surface area was measured at each time point using ImageJ software (National Institutes of Health; http://rsbweb.nih.gov/ij/).

Smad2/3 nuclear localization

HLMFs were grown on eight-well chamber slides and serum-starved for 24 h prior to the experiment. The cells were either unstimulated or stimulated with TGF-β₁ (10 ng/ml) in the presence of serum-free medium alone, 0.1% ethanol control, LXA₄ 10⁻¹⁰ mol, or LXA₄ 10⁻⁸ mol. After 1 h, cells were immunostained using rabbit monoclonal anti-Smad2/3 (0.174 μg/ml; Cell Signaling Technology). Secondary Ab labeled with FITC (F0313; DakoCytomation) was applied and the cells counterstained with DAPI (Sigma-Aldrich). Cells were mounted with fluorescent mounting medium and coverslipped. Images were analyzed as above. The intensity of nuclear FIGURE 1. HLMFs express ALXR. (A) Representative histogram for ALXR staining assessed by flow cytometry in HLMFs obtained from an IFP donor. (B) Both NFC- (n = 3) and IFP-derived (n = 3) HLMFs expressed ALXR constitutively (p = 0.0056, pooled data). ALXR expression was not increased following 24 h of treatment with TGF-β₁.
Smad2/3 staining was quantified by measuring the grayscale intensity of DAPI-positive nuclei to whole-cell staining.

Quantitative RT-PCR

HLMF RNA was isolated using the RNeasy Plus Kit (Qiagen, West Sussex, U.K.) according to the manufacturer’s instructions. Primers were designed for sSMa (ACT2A): forward, 5'-TTCAATGCTCCAGCATTGA-3' and reverse, 5'-CGAGGATGAGCAGCTTAC-3'; and for sMMa: forward, 5'-AAAGCCTGGAGAGGAATCTG-3' and reverse, 5'-GGGCTTGTCTGGAAAAGA-3'. PCR products were run on a 1.5% agarose gel to confirm the specificity of the primers.

Collagen secretion assay

HLMFs were cultured in serum-free medium alone or 0.1% ethanol control and stimulated with TGF-β1 10 ng/ml in the presence of ethanol control, and LXA4 at 10⁻¹⁰ or 10⁻⁸ mol for 24 h. Soluble collagen re-

FIGURE 2. Constitutive sSMa and stress fiber formation is attenuated by LXA4. (A) Representative immunofluorescent images from an NFC donor showing the decrease in sSMa expression in HLMFs following incubation with LXA4 (10⁻¹⁰ and 10⁻⁸ mol). Original magnification ×100. (B) sSMa expression was assessed by measuring grayscale intensity. LXA4 decreased sSMa expression at 10⁻¹⁰ and 10⁻⁸ mol in NFC-derived and IPF-derived HLMFs (n = 6 and n = 3, respectively, data pooled) (p < 0.0001, repeated-measures ANOVA, *p = 0.0001, **p < 0.0001, corrected by Sidak multiple-comparison test). For each donor, a minimum of 10 cells per field were measured and the mean taken. (C) In both NFC (n = 6) and IPF-derived (n = 6) HLMFs, sSMa was attenuated by LXA4 10⁻⁸ mol (two-way ANOVA corrected by Sidak multiple-comparison test; NFC, *p = 0.0004; IPF, *p = 0.0002). (D) Cells were noticeably more spindle-like following treatment with LXA4; a representative image from an IPF donor is shown. Original magnification ×200. (E) An ImageJ macro (National Institutes of Health) was used to quantify the number of actin filaments, and a minimum of 10 cells from each donor was assessed and averaged. LXA4 decreased the number of actin filaments at both 10⁻¹⁰ and 10⁻⁸ mol in both NFC- and IPF-derived cells (n = 6 and n = 4, respectively, data pooled) (p = 0.0003, repeated-measures ANOVA, *p = 0.0135, **p = 0.0005, corrected by Sidak multiple-comparison test). (F) IPF-derived HLMFs expressed increased numbers of SMA filaments (stress fibers) in comparison with NFC-derived cells (p = 0.0177). Actin filaments in both NFC- (n = 6) and IPF-derived (n = 6) HLMFs were attenuated by LXA4 10⁻⁸ mol (two-way ANOVA corrected by Sidak multiple-comparison test; NFC, **p = 0.0005; IPF, ***p < 0.0001).
LXA₄ ATTENUATES PROFIBROTIC HUMAN MYOFIBROBLAST ACTIVITY

Statistical analysis
Experiments from an individual donor were performed either in duplicate or triplicate, and a mean value was derived for each condition. Data distribution across donors was tested for normality using the Kolmogorov-Smirnov test. For parametric data, the one-way ANOVA or repeated-measures ANOVA for across-group comparisons was used followed by the appropriate multiple-comparison post hoc test; otherwise an unpaired or paired test was used. For nonparametric data, the Friedman test was used for across group comparisons followed by the appropriate multiple-comparison post hoc test, or the Wilcoxon signed-rank test was used where there were paired groups. GraphPad Prism for windows (version 6; GraphPad Software, San Diego, CA) was used for these analyses. A p value < 0.05 was taken to assume statistical significance, and data are represented as mean (± SEM) or median (interquartile ratio).

Results
HLMFs express LXA₄ receptors
LXA₄ acts via activation of the ALXR G-protein–coupled receptor (also known as FPR2, FPRL1, FPRH1, RFP, and HM63) in low-nanomole concentrations. The functions of this receptor, however, are cell specific; in neutrophils, LXA₄-ALXR interactions inhibit migration, but in monocytes, these can stimulate chemotaxis (34).

NFC- and IPF-derived HLMFs expressed ALXR (FPRL1) with a whole population shift in comparison with the control Ab (p = 0.0056, Mann–Whitney U test) (Fig. 1A). There was a trend for a higher expression in the IPF-derived myofibroblasts, although this was not statistically significant, and expression of ALXR did not change following 24 h of TGF-β1 stimulation (Fig. 1B). Thus, HLMFs express LXA₄ receptors.

Constitutive αSMA expression and actin stress fiber formation is inhibited by LXA₄
We and others have shown that fibroblasts obtained from human lung parenchyma express high quantities of αSMA and have the typical myofibroblast contractile phenotype (27, 29, 35, 36). Furthermore, these HLMFs derived from IPF donors express higher numbers of actin stress fibers constitutively than cells from NFC donors (15). After 48 h of treatment with LXA₄ (10⁻¹⁰ and 10⁻⁸ mol), the amount of constitutive αSMA staining was dose dependently reduced (Fig. 2A–C). Following treatment with LXA₄ cells were less stellate and became more spindle like, a similar morphology to inactivated fibroblasts (Fig. 2D). IPF-derived HLMFs again expressed more αSMA stress fibers at baseline in comparison with NFC-derived cells (p = 0.0177). LXA₄ reduced the number of actin stress fibers in both IPF- and NFC-derived cells and to a similar extent (Fig. 2E, 2F).

Constitutive HLMF contraction is inhibited by LXA₄
One of the main features of a myofibroblast is its ability to drive tissue repair and wound closure by reorganizing the ECM via contraction (37). We therefore investigated the effects of LXA₄ on constitutive HLMF contraction. HLMF contraction was examined over 24 h in the presence of LXA₄ at 10⁻¹⁰ and 10⁻⁸ mol using collagen gels (Fig. 3A). With both NFC- and IPF-derived HLMFs, basal contraction was dose dependently reduced by LXA₄ (p = 0.0009 and p = 0.0007, respectively, for LXA₄ at 10⁻⁸ mol) (Fig. 3B).

Constitutive HLMF Smad2/3 nuclear translocation is inhibited by LXA₄
It has previously been reported that αSMA expression and stress fiber formation in myofibroblasts is regulated in part by the TGF-β1/Smad signaling pathway (10, 11). As LXA₄ inhibited both consti-

FIGURE 3. Basal HLMF contraction and Smad2/3 nuclear translocation are inhibited by LXA₄. (A) Representative images from an NFC donor showing the spontaneous contraction of HLMFs within a collagen gel and its suppression by LXA₄. (B) Constitutive HLMF contraction was significantly attenuated by LXA₄ (10⁻⁸ mol) in both NFC- (n = 6) and IPF-derived (n = 5) cells (two-way ANOVA corrected by Sidak multiple-comparison test; NFC, *p = 0.0009; IPF, **p = 0.0001). (C) Representative images from an IPF donor displaying total Smad2/3 expression within HLMFs. At baseline, the HLMFs have staining both in the nucleus and within the cytoplasm, which is reduced upon incubation with LXA₄ (10⁻⁸ mol) for 1 h. (D) The ratio of total Smad2/3 nuclear to whole-cell staining was assessed by measuring grayscale intensity. IPF-derived (n = 6) HLMF demonstrated increased expression of total Smad2/3 within the nucleus in comparison with NFC donors (n = 6) (*p = 0.043, Mann–Whitney U test). LXA₄ (10⁻⁸ mol) significantly attenuated the amount of Smad2/3 localized to the nucleus in both NFC- and IPF-derived cells (two-way ANOVA corrected by Sidak multiple-comparison test; NFC, *p = 0.0254; IPF, **p = 0.0006).
tutive αSMA expression and HLMF contraction, we examined whether LXA₄ disrupts constitutive Smad2/3 nuclear translocation using immunofluorescent staining. HLMFs had detectable Smad2/3 within the nucleus at baseline, and the IPF-derived HLMFs displayed a higher proportion of nuclear staining in comparison with the NFC-derived cells (p = 0.043), in keeping with previous work (15). This nuclear Smad2/3 immunostaining was reduced and to a similar extent in both IPF- and NFC-derived HLMFs in the presence of LXA₄ (10⁻⁸ mol) for 1 h (Fig. 3C, 3D).

Next, we investigated whether LXA₄ inhibits TGF-β₁-induced profibrotic activity in HLMFs. Cells were treated with TGF-β₁ in the presence of 0.1% ethanol control or LXA₄ at 10⁻¹⁰ and 10⁻⁸ mol, and flow cytometry was performed. In comparison with vehicle control, TGF-β₁ stimulation significantly increased αSMA protein expression in both NFC- and IPF-derived HLMFs (p = 0.0070) (Fig. 4A). The TGF-β₁–dependent increase in αSMA expression was significantly inhibited in IPF-derived cells in the presence of LXA₄ 10⁻¹⁰ and 10⁻⁸ mol (**p = 0.0274, paired t test). No significant difference was found between NFC- and IPF-derived HLMFs in terms of TGF-β₁–stimulated αSMA expression (p = 0.25). TGF-β₁–induced αSMA expression and contraction are inhibited by LXA₄ in HLMFs

![Figure 4](http://www.jimmunol.org/)

**FIGURE 4.** TGF-β₁–dependent increases in αSMA mRNA and protein expression and HLMF contraction are attenuated by LXA₄. (A) Flow cytometry was used to assess the changes in αSMA expression following TGF-β₁ (10 ng/ml) stimulation in the presence of LXA₄, in both NFC- (n = 4) and IPF-derived (n = 3) HLMFs. αSMA expression in HLMFs was significantly increased following TGF-β₁ stimulation (**p = 0.0070, paired t test). LXA₄ significantly attenuated TGF-β₁–dependent increases in αSMA expression at 10⁻¹⁰ and 10⁻⁸ mol (**p = 0.008, respectively; repeated-measures ANOVA corrected by Sidak multiple-comparison test, statistics were performed on pooled data). (B) Representative fluorescent histogram showing αSMA expression in HLMFs under the above conditions. (C) Densitometry results of Western blot analysis indicating the increased αSMA expression following TGF-β₁ (10 ng/ml) stimulation for 24 h in IPF donors (*p = 0.0344, paired t test). This increase was significantly attenuated by LXA₄ 10⁻⁸ mol (**p = 0.0274, paired t test). No significant difference was found between NFC- and IPF-derived HLMFs in terms of TGF-β₁–stimulated αSMA expression (p = 0.25). (D) Quantitative PCR results displaying the relative expression of αSMA in HLMFs following 24 h of stimulation with TGF-β₁ (10 ng/ml) in the presence of 0.1% ethanol or LXA₄ at 10⁻¹⁰ and 10⁻⁸ mol. TGF-β₁ significantly upregulated αSMA mRNA expression in both NFC- (n = 6) and IPF-derived (n = 5) HLMFs (p = 0.018, one-sample t test). IPF-derived HLMFs demonstrated a significantly greater increase in mRNA expression in comparison with NFC-derived cells (*p = 0.0261). TGF-β₁–dependent upregulation of αSMA mRNA expression was significantly inhibited in IPF-derived cells in the presence of LXA₄ 10⁻¹⁰ and 10⁻⁸ mol (***p = 0.0033, respectively, two-way ANOVA, corrected by Sidak multiple-comparison test). (E) Representative images from an IPF donor showing the TGF-β₁–stimulated contraction of HLMFs within a collagen gel and its suppression by LXA₄. (F) HLMFs from both NFC- (n = 6) and IPF-derived (n = 5) donors displayed increased contraction following TGF-β₁ (10 ng/ml) stimulation (**p = 0.0005, repeated-measures ANOVA, *p = 0.0057, **p = 0.0006, corrected by Dunn multiple-comparison test).
mRNA expression was significantly upregulated following 24 h of TGF-

\[ \text{TGF-} \beta_1 \text{ stimulation in NFC- and IPF-derived HLMFs} \] 

(\( * p = 0.0064 \), one-sample t test, pooled data; NFC, \( n = 5 \), and IPF, \( n = 5 \)). This increase in HLMF proliferation was significantly reduced with LXA\(_4\) at both 10\(^{-10}\) and 10\(^{-8}\) mol \(( p = 0.0001, \text{repeated-measures ANOVA, } * p = 0.0001, ** p = 0.001, \) respectively, corrected by Dunn multiple-comparison test).

Similarly, TGF-\( \beta_1 \)-dependent stimulation increased \( \alpha \text{SMA mRNA expression in HLMFs, which was significantly greater in IPF-derived HLMFs compared with NFC-derived cells} \( ( p = 0.0261) \). This TGF-\( \beta_1 \)-dependent \( \alpha \text{SMA mRNA expression was significantly reduced in IPF-derived HLMFs following treatment with LXA}\(_4\) at 10\(^{-10}\) and 10\(^{-8}\) mol \(( p = 0.0479 \) and \( p = 0.0033, \) respectively, two-way ANOVA) \(( \text{Fig. 4D})\), but not NFC-derived cells.

To study the effects of LXA\(_4\) on TGF-\( \beta_1 \)-dependent HLMF contraction, HLMFs were cultured within collagen gels and their contraction monitored over 24 h. Pictures were taken at 0 and 24 h and the contraction measured using ImageJ software (National Institutes of Health); representative images are displayed in Fig. 4E. TGF-\( \beta_1 \) stimulation increased HLMF contraction in comparison with vehicle control \((0.1\% \text{ ethanol}) \) \(( p = 0.0026)\), with no differences in response between NFC- and IPF-derived cells \(( \text{Fig. 4F})\). LXA\(_4\) significantly reduced TGF-\( \beta_1 \)-dependent HLMF contraction at both 10\(^{-10}\) and 10\(^{-8}\) mol \(( p = 0.0057)\) and 10\(^{-8}\) mol \(( p = 0.0006)\). Thus, LXA\(_4\) not only inhibits constitutive HLMF \( \alpha \text{SMA expression and contraction, but also the increased} \alpha \text{SMA expression and contraction induced by the potent profibrotic mediator TGF-} \beta_1 \) \( (38, 39)\).

TGF-\( \beta_1 \)-induced collagen mRNA expression and collagen secretion is inhibited by LXA\(_4\)

To further elucidate the inhibitory effects of LXA\(_4\) we investigated mRNA expression of collagen type I and type IV, which are two of the most abundant collagens found within the IPF lungs \((39, 40)\).

Collagen type I mRNA expression was significantly increased by FBS-dependent HLMF proliferation is inhibited by LXA\(_4\) at 10\(^{-10}\) mol \(( p = 0.0106)\) and 10\(^{-8}\) mol \(( p = 0.0076)\) \(( \text{Fig. 4A, 4B})\). This was also confirmed by Western blot analysis, \( \alpha \text{SMA expression in IPF-derived HLMFs but not NFC-derived cells, and which was significantly attenuated by LXA}\(_4\) at 10\(^{-8}\) mol \(( p = 0.0274)\) \(( \text{Fig. 4C})\).

Collagen type IV mRNA expression was significantly greater in IPF-derived HLMFs in comparison with NFC-derived cells \(( p = 0.0214)\), one-sample t test on pooled data). LXA\(_4\) significantly reduced the TGF-\( \beta_1 \)-dependent increases in collagen type IV mRNA expression in IPF HLMFs \(( p = 0.0031)\) and to a similar extent in both NFC- and IPF-derived HLMFs \(( p = 0.0039, \) two-way ANOVA) \(( \text{Fig. 4D})\), but not NFC-derived cells.

The amount of collagen secreted by both NFC- and IPF-derived HLMFs increased significantly following TGF-\( \beta_1 \) \( (10 \text{ ng/ml}) \) for 24 h, with no difference between NFC and IPF \(( ** p = 0.0022 \) on pooled data; NFC, \( n = 5 \), and IPF, \( n = 4 \)). LXA\(_4\) significantly inhibited collagen secretion at both 10\(^{-10}\) and 10\(^{-8}\) mol \(( * p = 0.0015, ** p = 0.0002, \) two-way ANOVA, pooled data).

FIGURE 5. LXA\(_4\) significantly decreases TGF-\( \beta_1 \)-dependent increases in collagen mRNA expression and collagen secretion. (A) Collagen type I mRNA expression was significantly upregulated following 24 h of TGF-\( \beta_1 \) stimulation in NFC- and IPF-derived HLMFs \(( n = 6 \) and \( n = 5 \), respectively) \(( * p = 0.0064, \) one-sample t test on pooled data). LXA\(_4\) significantly reduced TGF-\( \beta_1 \)-dependent upregulation of collagen type I mRNA at 10\(^{-8}\) mol \(( p = 0.0214, \) one-way ANOVA, * \( p = 0.0057, \) corrected by Sidak multiple-comparison test). (B) Collagen type IV mRNA expression was significantly upregulated following 24 h of TGF-\( \beta_1 \) stimulation in NFC- and IPF-derived HLMFs \(( n = 7 \) and \( n = 5 \), respectively) \(( * p = 0.0031 \) and *** \( p < 0.0001, \) respectively, two-way ANOVA corrected by Sidak multiple-comparison test). The TGF-\( \beta_1 \)-dependent increase in collagen type IV mRNA expression was significantly greater in IPF-derived HLMFs in comparison with NFC-derived cells \(( * p = 0.0480, \) unpaired t test). The TGF-\( \beta_1 \)-dependent increase in collagen type IV mRNA expression in IPF HLMFs was significantly reduced by LXA\(_4\) at 10\(^{-8}\) mol, ** \( p = 0.0039, \) two-way ANOVA, corrected by Sidak multiple-comparison test).

FIGURE 6. FBS-dependent HLMF proliferation is inhibited by LXA\(_4\) at 10\(^{-10}\) mol \(( p = 0.0106)\) and 10\(^{-8}\) mol \(( p = 0.0076)\) \(( \text{Fig. 4A, 4B})\). This was also confirmed by Western blot analysis, in which TGF-\( \beta_1 \) increased \( \alpha \text{SMA expression in IPF-derived HLMFs but not NFC-derived cells, and which was significantly attenuated by LXA}\(_4\) at 10\(^{-8}\) mol \(( p = 0.0274)\) \(( \text{Fig. 4C})\).
TGF-β1 in both NFC- and IPF-derived HLMFs compared with control (p = 0.0064, one-sample t test, pooled data) (Fig. 5A). This increase was significantly reduced by LXA4 at 10^{-8} mol in both NFC- and IPF-derived cells (p = 0.0057, one-way ANOVA corrected by Dunnett multiple-comparison test) (Fig. 5A). Similarly, collagen type IV mRNA expression was significantly increased in both NFC- and IPF-derived cells (p = 0.0031 and p < 0.0001, respectively, two-way ANOVA corrected by Dunnett multiple-comparison test). TGF-β1–induced collagen type IV mRNA expression was significantly increased in both NFC- and IPF-derived HLMFs (p = 0.0031 and p < 0.0001, respectively, two-way ANOVA corrected by Dunnett multiple-comparison test). Similarly, collagen type IV mRNA expression was significantly increased in both NFC- and IPF-derived HLMFs (p = 0.0031 and p < 0.0001, respectively, two-way ANOVA corrected by Dunnett multiple-comparison test). Similarly, collagen type IV mRNA expression was significantly increased in both NFC- and IPF-derived HLMFs (p = 0.0031 and p < 0.0001, respectively, two-way ANOVA corrected by Dunnett multiple-comparison test).

The ability of LXA4 to downregulate TGF-β1–increased collagen mRNA was paralleled by a reduction in total collagen secretion measured using the Sircol assay. TGF-β1 significantly increased the amount of total collagen secreted by NFC- and IPF-derived cells (p = 0.0022), which was dose-dependently inhibited by LXA4 (10^{-10} mol, p = 0.0015; 10^{-8} mol, p = 0.0002) (Fig. 5C).

FBS-induced HLMF proliferation is attenuated by LXA4
HLMF proliferation was assessed after 48 h of stimulation with 10% FBS, which significantly increased proliferation (p = 0.0006) (Fig. 6). In both NFC- and IPF-derived HLMFs, FBS-dependent proliferation was significantly decreased by LXA4 at 10^{-10} mol (p = 0.0001) and 10^{-8} mol (p = 0.0001) (Fig. 6). In summary, FBS-induced HLMF proliferation is attenuated by treatment with LXA4.

TGF-β1–dependent Smad2/3 nuclear translocation is disrupted by LXA4
The ability of LXA4 to attenuate both constitutive Smad2/3 nuclear localization and several TGF-β1–dependent cell processes in HLMFs suggested that LXA4 may also attenuate TGF-β1–dependent Smad2/3 nuclear translocation. Phosphorylation is a key initial event in the activation of these Smad proteins. Using Western blot analysis, we therefore investigated the effect of LXA4 on TGF-β1–induced phosphorylation of Smad2/3 and the expression of total Smad2/3 in HLMFs. As previously reported in many studies, TGF-β1 significantly increased Smad2/3 phosphorylation in HLMFs (p = 0.0110). However, LXA4 at 10^{-10} and 10^{-8} mol had no significant effect on the TGF-β1–dependent increase in Smad2/3 phosphorylation in either NFC- or IPF-derived HLMFs. (A) Using Western blot analysis, we investigated the effect of LXA4 on TGF-β1–induced phosphorylation of Smad2/3, a representative image from an NFC donor is shown. TGF-β1 significantly increased Smad2/3 phosphorylation in HLMFs (p = 0.0110; NFC, n = 2; and IPF, n = 3). However, LXA4 at 10^{-10} and 10^{-8} mol had no significant effect on the TGF-β1–dependent increase in Smad2/3 phosphorylation in either NFC- or IPF-derived HLMFs. (C) Immunofluorescent analysis of total Smad2/3 nuclear translocation showed a significant increase in both NFC (n = 5) and IPF (n = 4) HLMFs (p = 0.0001, *p = 0.0007, respectively). This TGF-β1–dependent increase in total nuclear translocation was significantly and dose dependently attenuated by LXA4 (two-way ANOVA corrected by Sidak multiple-comparison test; NFC, 10^{-8} mol, #p = 0.0051; IFP, 10^{-10} mol, **p = 0.0208 and 10^{-8} mol, ***p = 0.0011). (D) In both NFC- (n = 6) and IPF-derived (n = 6) HLMFs, TGF-β1–dependent total Smad2/3 nuclear translocation was attenuated by LXA4 10^{-8} mol (two-way ANOVA corrected by Sidak multiple-comparison test; NFC, #p = 0.0003, **p = 0.00037; IPF, *p = 0.0002, ***p = 0.0003). (E) Representative immunofluorescent images from an NFC donor demonstrating the increased nuclear translocation of total Smad2/3 following TGF-β1 stimulation and the inhibition of this by LXA4 (10^{-8} mol).

**FIGURE 7.** LXA4 does alter Smad2/3 phosphorylation but exerts its effect through inhibition of Smad2/3 translocation to the nucleus. (A and B) Using Western blot analysis, we investigated the effect of LXA4 on TGF-β1–induced phosphorylation of Smad2/3, a representative image from an NFC donor is shown. TGF-β1 significantly increased Smad2/3 phosphorylation in HLMFs (p = 0.0110; NFC, n = 2; and IPF, n = 3). However, LXA4 at 10^{-10} and 10^{-8} mol had no significant effect on the TGF-β1–dependent increase in Smad2/3 phosphorylation in either NFC- or IPF-derived HLMFs. (C) Immunofluorescent analysis of total Smad2/3 nuclear translocation showed a significant increase in both NFC (n = 5) and IPF (n = 4) HLMFs (p = 0.0007, *p = 0.0007, respectively). This TGF-β1–dependent increase in total nuclear translocation was significantly and dose dependently attenuated by LXA4 (two-way ANOVA corrected by Sidak multiple-comparison test; NFC, 10^{-8} mol, #p = 0.0051; IFP, 10^{-10} mol, **p = 0.0208 and 10^{-8} mol, ***p = 0.0011). (D) In both NFC- (n = 6) and IPF-derived (n = 6) HLMFs, TGF-β1–dependent total Smad2/3 nuclear translocation was attenuated by LXA4 10^{-8} mol (two-way ANOVA corrected by Sidak multiple-comparison test; NFC, #p = 0.0003, **p = 0.00037; IPF, *p = 0.0002, ***p = 0.0003). (E) Representative immunofluorescent images from an NFC donor demonstrating the increased nuclear translocation of total Smad2/3 following TGF-β1 stimulation and the inhibition of this by LXA4 (10^{-8} mol).
no significant effect on the TGF-β1–dependent increase in Smad2/3 phosphorylation in either NFC- or IPF-derived HLMFs (Fig. 7A, 7B).

Once TGF-β1 has induced phosphorylation of Smad2/3, they interact with Smad4, and this complex translocates to the nucleus to initiate gene transcription. Although Smad2/3 phosphorylation was not inhibited, TGF-β1–dependent Smad2/3 nuclear translocation was significantly attenuated by LXA₄ (Fig. 7C–E). Thus LXA₄ appears to significantly disrupt TGF-β1–dependent nuclear translocation of Smad2/3, but not Smad2/3 phosphorylation.

Discussion

The myofibroblast is implicated as the key cell driving the progression of IPF through the synthesis of excess fibrotic extracellular matrix and tissue contraction. The myofibroblast is therefore an attractive target for novel antifibrotic therapies. In this study, we have demonstrated that HLMFs express LXA₄ receptors and that LXA₄ attenuates: 1) constitutive HLF mRNA expression, collagen secretion, and Smad2/3 nuclear localization; 2) TGF-β1–dependent increases in HLF mRNA expression, contraction, collagen mRNA expression, collagen secretion, and Smad2/3 nuclear localization; and 3) serum-dependent HLF proliferation.

Fibroblasts and myofibroblasts demonstrate marked functional and phenotypic heterogeneity between tissues and across species. As an example, there is a marked difference in the phenotype of fibroblasts grown from human airway and lung parenchyma, with those from lung spontaneously displaying a myofibroblast phenotype (29, 35, 36). When considering novel therapeutic targets, it is therefore important to study cells from the species, tissue compartment and disease of interest. Expression of the LXA₄ receptor ALXR (FPRL1) has been demonstrated previously in human synovial fibroblasts by RT-PCR (41), and these cells and rat fibroblast cell lines respond to LXA₄ implying functional receptor expression (22–41). In this study, we have demonstrated that ALXR protein is expressed on the surface of the majority of parenchymal HLMFs derived from both NFC and IPF tissue.

In a rat fibroblast cell line, LXA₄ at 10⁻⁸ mol attenuated TGF-β1–dependent Smad2 phosphorylation (but not Smad3 phosphorylation) and MAPK activation, and inhibited TGF-β1–dependent gene transcription (22). We also found that LXA₄ inhibited TGF-β1–dependent gene transcription, but in contrast to Börgeson et al. (22), we could not detect inhibition of Smad2/3 phosphorylation, although there was reduced TGF-β1–dependent nuclear Smad2/3 translocation. The means by which LXA₄ would prevent nuclear translocation of activated Smads without affecting phosphorylation is intriguing and will require further work to elucidate the mechanism. Nevertheless, the ability of LXA₄ to inhibit Smad nuclear localization is in keeping with its ability to inhibit TGF-β1–dependent gene transcription and the downstream production of collagen and αSMA in HLMFs.

Several phenotypic differences have been observed previously between control and IPF-derived HLMFs in culture, suggesting that there may be genetic and/or epigenetic changes that promote a profibrotic HLMF phenotype in patients who develop IPF. Interestingly, we found that LXA₄ not only reduced TGF-β1–dependent profibrotic responses, but promoted HLF differentiation toward a fibroblast phenotype by reducing constitutive αSMA actin expression and actin stress fiber formation. This in turn is likely to explain the reduced constitutive HLF contraction evident in collagen gels. This occurred in conjunction with a reduction in nuclear Smad2/3 immunostaining, which occurred within 1 h of LXA₄ exposure, suggesting there is a component of constitutive Smad2/3 signaling in HLMFs at rest. This ability of LXA₄ to promote dedifferentiation toward a fibroblast phenotype suggests that if there is a degree of constitutive profibrotic HLF activity in IPF lungs due to genetic/epigenetic factors, LXA₄ or a stable analog might be a particularly useful therapy.

In addition to the inhibition of TGF-β1–dependent stimulation, we found that LXA₄ also inhibited HLF proliferation induced by serum, and this is in keeping with previous work showing that LXA₄ inhibited connective tissue growth factor–dependent proliferation of a human fibroblast cell line (25). Previous studies using LXA₄ in cell-culture systems suggest it is highly active in the nanomole range. Our data are consistent with this, with effects readily evident in HLMFs at 10⁻¹⁰ mol (0.1 nmol), although more consistent at 10⁻⁸ mol.

In summary, we have shown that LXA₄ inhibits many TGF-β1–dependent profibrotic responses in healthy and IPF-derived HLMFs, which may result from the inhibition of Smad2/3 nuclear translocation. Furthermore, LXA₄ promotes HLF dedifferentiation in the resting state, suggesting it may have the potential to reverse the fibrotic process. In support of this, and of particular relevance to this study, a stable epi-LXA4 analog markedly inhibited bleomycin-induced pulmonary fibrosis in mice when administered either preventively or curatively, with reversal of fibrosis evident in the latter (26). This was associated with a reduction in the accumulation and differentiation of myofibroblasts in the lung parenchyma. Thus, there are consistent in vitro and in vivo data from primary HLMFs and the mouse bleomycin model, respectively, indicating that LXA₄ or its stable analogs may not only prevent the progression of lung fibrosis, but also potentially reverse it. This indicates that clinical trials of LXA₄ analogs should be considered in patients with IPF.
