Conclusion. Short course IV antibiotics for ≥ 48 hours for young infants with nonbacteremic UTI are safe provided bacterial meninitis has been excluded. Treatment failure and serious complications were rare in young infants with UTI.

1438. Prevalence and Risk Factors for Extended Spectrum Betalactamases Among Hospitalized Patients with Community-Acquired Pyelonephritis in Colombia Mariana Franco Ribeiro, 23255479; Jorge Cortes, MD; 1Universidad Nacional de Colombia: Hospital Universitario Nacional, Bogotá, Cundinamarca, Colombia; Universidad Nacional de Colombia, Bogota, Distrito Capital de Bogota, Colombia

Session: P-81. UTIs

Background. Urinary tract infections (UTI) are the most frequent bacterial infection in hospitalized patients. Extended spectrum betalactamases (ESBL) producing bacteria have become more prevalent. Escherichia coli (E. coli) is the most frequent ESBL producing bacteria isolated in UTI. This drug resistant organisms are associated with poorer outcomes for patients. In low income countries, approaching to and treating ESBL E. coli, represent a major challenge for health care centers.

Methods. A retrospective cohort of adult patients with community acquired pyelonephritis caused by Escherichia coli was identified in a tertiary hospital in Colombia. Susceptibility was performed with Vitek (BioMerieux, France); extended spectrum beta lactamase (ESBL) production was defined phenotypically. Inclusion criteria were adult patients hospitalized with a positive urine culture for E. coli. Demographic and clinical characteristics were searched in electronic records. Risk factors associated with ESBL production were identified by using a multivariate logistic regression analysis.

Results. During 7 years 817 patients with pyelonephritis caused by E. coli were identified (97.9%) of them were caused by ESBL producers. Women were 66% and 408 (74.8%) of them had menopause. Mean age was 64.2 years (standard deviation of 19.1). Of the cohort, 481 (561.1%) had at least some comorbidity and was frequent to find diabetes (18.5%), immunosuppression due to oncologic disease or medications (18.4%), urolithiasis or previous surgical procedures (17%). After logistic regression, risk factors identified to predict ESBL production, were: being a man (aOR 5.4, 2.1-18.2), a woman with menopause (aOR 2.9, 1.3-9.9), and the Charlson score (aOR 0.83, 0.73 – 0.96). Previous antibiotic use was not related to ESBL infection. Conclusion. In this relatively large cohort of patients with pyelonephritis caused by E. coli, ESBL production risk factors were not clearly identified other than sex and menopause. Curiously, Charlson score predicted a lower risk of resistance. Other factors (food consumptions and others) might be driving the resistance in the community in E. coli.

1439. Epidemiology and 12-Month Antibiotic Use in the Outpatient Setting among Adult Patients with Complicated Urinary Tract Infections: A Retrospective Database Analysis Thomas Lodise, Jr., PharmD, PhD; 1Thomas Lodise, Jr., PharmD, PhD; 1Janna Manjelievskaia, PhD, MPH; 1Matthew Brouillette, MPH; 1Kate Sulham, MPH; 1Albany College of Pharmacy and Health Sciences, Albany, NY; 1IBM Watson Health, Cambridge, Massachusetts; 1Spero Therapeutics, Cambridge, MA

Session: P-81. UTIs

Background. Complicated urinary tract infections (cUTI) are one of the most common bacterial infections and represent substantial burden to the health care system. In the United States, patients with cUTI in a large US database containing longitudinal inpatient (IP) and outpatient (OP) patient-level data.

Methods. We conducted a retrospective cohort study of adult patients in the IBM MarketScan® Commercial or Medicare Supplemental Databases with at least 1 IP or non-diagnostic OP claim with a diagnosis for cUTI between January 1, 2017 and June 30, 2019. Patients meeting the following criteria were included for analysis: (1) ≥18 years of age on the index date, (2) ≥6 months of continuous enrollment (CE) with medical and pharmacy benefits prior to the index date, (3) ≥212 months of CE following the index date or evidence of death, and (4) no evidence of a prior cUTI during the 6-month baseline period. Demographics and clinical characteristics were stratified. Patients were classified as IP if they were hospitalized during 30-day post index date; remaining patients were classified as OP. Antibiotics received in the OP setting in the 12-months post index date were examined.

Results. 95,423 patients met study criteria. Most (86.4%) patients were Commercially insured, mean (SD) age was 53.6 (18.1) and 70.4% were female. Mean baseline Charlson Comorbidity Index was 0.77. During the 30-day post index date, 22.2% were treated as IP and 77.8% were strictly treated as OP. In the 12-month OP follow-up period among index IP, 78.2% required ≥ 2 antibiotics, 38.2% required ≥4 antibiotics, and 41.6% received an IV antibiotic. In the 12 months OP follow-up period among index OP, 81.8% required ≥2 antibiotics, 38.2% required ≥ 4 antibiotics, and 46.8% received an IV antibiotic. For both IP and OP, fluoroquinolones were the most common oral antibiotic class (57.7%), followed by cephalosporins (39.2%), penicillins (30.3%), trimethoprim-sulfamethoxazole (29.8%), and nitrofurantoin (25.2%). Cephalosporins were the most common IV antibiotic class (38.5%).

Conclusion. Regardless of index treatment setting, approximately 40% of all cUTI patients required ≥ 4 antibiotic therapy and almost half would receive an IV antibiotic in the outpatient setting in the 12-months post index date.

1440. Meta-analysis of the World Health Organization’s Guideline for the Treatment of Osteoarticular Infections 2018 Víctorio Callegaro, PhD, ultimately red and synthesized an HZ incidence rate for the general population using meta-analysis models.

Methods. A random-effects meta-analysis was conducted to estimate HZ incidence from a published worldwide systematic literature review (SLR) including only individuals aged 50 years and older. Meta-regression was used to explore if variability in incidence rates could be explained by a combination of study-specific characteristics in the base model: age, gender, continent and year of data collection. The impact of adding additional covariates: case detection, case definition, study design, incidence type, patient type and latitude to the base model was also assessed.

Results. 65 out of 69 studies from the SLR, were included in the analysis: 27 from Europe, 20 from North America, 11 from Asia and 7 from Oceania. There was much variability in study methodology and outcomes. Heterogeneity of incidence rates was greatest across studies conducted in Asia. Meta-analysis results showed that: incidence increased with age; was lower in males compared to females; was lower in Europe and North America compared to Asia and Oceania; and increased from the period prior to 2003 to the period after 2003. The final meta-regression model included continent, year of data collection, gender, age, cubic and quadratic terms for age, as well as an age x gender interaction term. The age x gender interaction suggests that the difference in incidence between males and females is greater in younger ages (e.g. 50-59), whereas in older age groups (e.g. 80+) incidence rates are similar between males and females. None of the additional covariates contributed significantly to the model. It was estimated that 15.5 in 2020 worldwide in individuals aged 50 years and older, which in the absence of vaccination, is projected to increase to 19.8 million by 2030.

Conclusion. The model allows for trends in incidence data to be explored based on influential covariates. Incidence rates were shown to vary by age, gender, continent, and over time.
