THE RADIAL MASA IN FREE ORTHOGRAL QUANTUM GROUPS

AMAURY FRESLON AND ROLAND VERGNIOUX

Abstract. We prove that the radial subalgebra in free orthogonal quantum group factors is maximal abelian and mixing, and we compute the associated bimodule. The proof relies on new properties of the Jones-Wenzl projections and on an estimate of certain scalar products of coefficients of irreducible representations.

1. Introduction

Discrete groups have been an important part of the theory of von Neumann algebras since its very beginning. Taking advantage of their algebraic or geometric properties, one can build interesting families of examples and counter-examples of von Neumann algebras, and get some insight into crucial structural properties like property (T) or approximation properties. In the last ten years, there has been an increasing number of results showing that discrete quantum groups can also produce interesting examples of von Neumann algebras. In this work, we continue this program by initiating the study of abelian subalgebras in von Neumann algebras of discrete quantum groups.

The importance of abelian subalgebras in the study of von Neumann algebras has been long known and, as already mentioned, group von Neumann algebras have played an important role in that history. For instance, the subalgebra generated by one of the generating copies of \( \mathbb{Z} \) inside the von Neumann algebra of the free group \( \mathbb{F}_2 \) was proved by J. Dixmier to be maximal abelian [7], and by S. Popa to be maximal injective [14], thus answering a long-standing question of R.V. Kadison. The fact that the subalgebra comes from a group inclusion was crucial there.

Another example of abelian subalgebra in free group factors is the so-called radial (or laplacian) subalgebra, which is the one generated by the sum of the generators and their inverses. This subalgebra does not come from a subgroup, hence the aforementioned techniques do not apply. S. Radulescu introduced in [16] tools to prove that this subalgebra, which was already known to be maximal abelian by work of S. Pytlik [15], is singular. His techniques were later used again to prove that the radial subalgebra is maximal amenable [3]. For more background on maximal abelian subalgebras we refer to the book [19].

In this paper, we study the analogue of the radial subalgebra in free quantum group factors. More precisely, we consider the free orthogonal quantum group of Kac type \( O_N^+ \) and, inside its von Neumann algebra \( L^\infty(O_N^+) \), the subalgebra generated by the characters of irreducible representations. Recall that \( O_N^+ \) is a compact quantum group introduced in [23], whose discrete dual is a quantum analogue of a free group. In particular \( L^\infty(O_N^+) \) plays the role of a free group factor \( L^\infty(\mathbb{F}_N) \). This analogy, dating back to the seminal works of T. Banica [1], [2], has been supported since then by further work of several authors who proved that the von Neumann algebra \( L^\infty(O_N^+) \), for \( N \geq 3 \), indeed shares many properties with free group factors:

- it is a full factor with the Akemann-Ostrand property [20],
- it has the Haagerup property [1] and the completely contractive approximation property [11],
- it is strongly solid [12] and has property strong \( HH \) [9],
- it satisfies the Connes embedding conjecture [5].

As far as the radial subalgebra is concerned, the techniques of S. Radulescu do not apply in the quantum case, because there is no clear way to mimic the construction of the so-called Radulescu basis. However, the properties of the radial algebra mentioned previously can all be proved using another tool which we briefly explain. Consider, for \( l \in \mathbb{N} \), the element \( w_l \in L(\mathbb{F}_N^l) \) which is the sum of all words of length \( l \). Then, if \( x, x' \) are two words of length \( k \) and \( y, y' \) are two other words of length \( n \), we have

\[
\langle (x - x')w_l, w_l(y - y') \rangle \leq 2 \min(k + 1, n + 1).
\]

Key words and phrases. Quantum groups, von Neumann algebras, MASAs.
This estimate can be proved by elementary counting arguments, similar to the ones in [18, Sec 4]. It can then be used to prove maximal abelianness and singularity in one shot. We will use the same strategy here.

Elements of the form $x - x'$ with $x$ and $x'$ of the same length $k$ form a basis of the orthogonal of the radial subalgebra in $L(F_N)$, in the quantum case their role will be played by the coefficients $u^k_{\xi \eta}$ of an irreducible representation $u^k$ with respect to vectors $\xi, \eta$ such that $\xi$ is orthogonal to $\eta$. The role of $w_1$ will be played by the character $\chi_1$ of the irreducible representation $u^1$ — note however that $\|w_1\|^2 = 2N(2N - 1)^{l-1}$ in $L^2(F_N)$, whereas $\|\chi_1\| = 1$ in $L^2(O_N^+)$. The estimate analogous to (1) that we will prove and use in the present article is then stated as follows (see Theorem 4.3):

$$\langle \chi u_{\xi, \eta}^k, w_{\xi, \eta}^n \chi \rangle \leq K q^{\max(l, l')},$$

with $q \in [0, 1]$. From this we will deduce all the results announced in the abstract.

Let us now outline the content of the paper. In Section 2, we recall some facts on compact quantum groups and in particular on free orthogonal quantum groups. Since the geometry of their representation theory will be crucial in the computations, we have to make some conventional choices and give the corresponding explicit formulæ for several related objects.

Section 3 and 4 form the core of the paper. There we prove the announced estimate for scalar products of coefficients and characters. The proof, presented in Section 4, is quite technical and relies on properties of the so-called Jones-Wenzl projections which are of independent interest and are established in Section 3.

Eventually, we prove in Section 5 all our structural results on the radial subalgebra, namely that it is left-linear and we will denote by $S.L.$ Woronowicz in [25]. In the sequel, all tensor products of C*-algebras are spatial and we denote by $\otimes$ the tensor product of von Neumann algebras.

**Acknowledgments.** We would like to thank Éric Ricard and Cyril Houdayer for interesting conversations. The first author was partially supported by the ERC Advanced Grant 339760 "Noncommutative distributions in free probability".

2. Preliminaries

In this section we give the basic definitions and results needed in the paper. All scalar products will be left-linear and we will denote by $B(H)$ the algebra of all bounded operators on a Hilbert space $H$. When considering an operator $X \in B(H_1 \otimes H_2)$, we will use the leg-numbering notations,

$$X_{12} := X \otimes 1, X_{23} := 1 \otimes X \text{ and } X_{13} := (\Sigma \otimes 1)(1 \otimes X)(\Sigma \otimes 1),$$

where $\Sigma : H_1 \otimes H_2 \to H_2 \otimes H_1$ is the flip map. For any two vectors $\xi, \eta \in H$, we define a linear form $\omega_{\xi, \eta} : B(H) \to \mathbb{C}$ by $\omega_{\xi, \eta}(T) = (T(\xi), \eta)$.

2.1. Compact quantum groups. We briefly review the theory of compact quantum groups as introduced by S.L. Woronowicz in [25]. In the sequel, all tensor products of C*-algebras are spatial and we denote by $\otimes$ the tensor product of von Neumann algebras.

**Definition 2.1.** A compact quantum group $\mathbb{G}$ is a pair $(C(\mathbb{G}), \Delta)$ where $C(\mathbb{G})$ is a unital C*-algebra and $\Delta : C(\mathbb{G}) \to C(\mathbb{G}) \otimes C(\mathbb{G})$ is a unital *-homomorphism such that

$$(\Delta \otimes \text{id} \circ \Delta = (\text{id} \otimes \Delta) \circ \Delta$$

and the spaces $\text{span}\{\Delta(C(\mathbb{G}))(1 \otimes C(\mathbb{G}))) \} \text{ and } \text{span}\{\Delta(C(\mathbb{G}))(C(\mathbb{G}) \otimes 1)\}$ are both dense in $C(\mathbb{G}) \otimes C(\mathbb{G})$.

According to [25] Thm 1.3], any compact quantum group $\mathbb{G}$ has a unique Haar state $h \in C(\mathbb{G})^*$, satisfying

$$(\text{id} \otimes h) \circ \Delta(a) = h(a)1 \text{ and } (h \otimes \text{id}) \circ \Delta(a) = h(a)1$$

for all $a \in C(\mathbb{G})$. Let $(L^2(\mathbb{G}), \pi_h, \Omega)$ be the associated GNS construction and let $C_{\text{red}}(\mathbb{G})$ be the image of $C(\mathbb{G})$ under the GNS representation $\pi_h$. It is called the reduced C*-algebra of $\mathbb{G}$ and its bicommutant in $B(L^2(\mathbb{G}))$ is the von Neumann algebra of $\mathbb{G}$, denoted by $L^\infty(\mathbb{G})$. To study this object, we will use representations of compact quantum groups.
Definition 2.2. A representation of a compact quantum group $G$ on a Hilbert space $H$ is an operator $u \in L^\infty(G)\mathcal{B}(H)$ such that $(\Delta \otimes \text{id})(u) = u_{12}u_{23}$. It is said to be unitary if the operator $u$ is unitary.

Definition 2.3. Let $G$ be a compact quantum group and let $u$ and $v$ be two representations of $G$ on Hilbert spaces $H_u$ and $H_v$, respectively. An intertwiner (or morphism) between $u$ and $v$ is a map $T \in \mathcal{B}(H_u, H_v)$ such that $v(\text{id} \otimes T) = (\text{id} \otimes T)u$. The set of intertwiners between $u$ and $v$ will be denoted by $\text{Hom}(u, v)$.

A representation $u$ is said to be irreducible if $\text{Hom}(u, u) = \mathbb{C}. \text{id}$ and it is said to be contained in $v$ if there is an injective intertwiner between $u$ and $v$. We will say that two representations are equivalent (resp. unitarily equivalent) if there is an intertwiner between them which is an isomorphism (resp. a unitary). Let us define two fundamental operations on representations.

Definition 2.4. Let $G$ be a compact quantum group and let $u$ and $v$ be two representations of $G$ on Hilbert spaces $H_u$ and $H_v$, respectively. The direct sum of $u$ and $v$ is the diagonal sum of the operators $u$ and $v$ seen as an element of $L^\infty(G)\mathcal{B}(H_u \oplus H_v)$. It is a representation denoted by $u \oplus v$. The tensor product of $u$ and $v$ is the element $u_{12}v_{13} \in L^\infty(G)\mathcal{B}(H_u \otimes H_v)$. It is a representation denoted by $u \otimes v$.

The theory of representations of compact groups can be generalized to this setting (see [25] Section 6). If $u$ is a representation of $G$ on a Hilbert space $H$ and if $\xi, \eta \in H$, then $u_{\xi\eta} = (\text{id} \otimes \omega_{\eta\eta})(u) \in C(G)$ is called a coefficient of $u$.

Theorem 2.5 (Woronowicz). Every representation of a compact quantum group is equivalent to a unitary one. Every irreducible representation of a compact quantum group is finite-dimensional and every unitary representation is unitarily equivalent to a sum of irreducible ones. Moreover, the linear span of the coefficients of all irreducible representations is a dense Hopf $*$-subalgebra of $C(G)$ denoted by $\text{Pol}(G)$.

2.2. Irreducible representations. Let $\text{Irr}(G)$ be the set of equivalence classes of irreducible unitary representations of $G$. For $\alpha \in \text{Irr}(G)$, we will denote by $u^\alpha$ a representative of the class $\alpha$ and by $H_\alpha$ the finite-dimensional Hilbert space on which $u^\alpha$ acts. The scalar product induced by the Haar state can be easily computed on coefficients of irreducible representations by [25] Eq. 6.7:}

$$\left\langle u^\alpha_{\xi\eta}, u^\beta_{\xi'\eta'} \right\rangle = \delta_{\alpha,\beta}\frac{\langle \xi, \xi' \rangle \langle \eta, \eta' \rangle}{d_\alpha},$$

where $d_\alpha$ is a positive matrix determined by the representation $\alpha$ and $d_\alpha = \text{Tr}(Q_\alpha) = \text{Tr}(Q_\alpha^{-1}) > 0$ is called the quantum dimension of $\alpha$. Note that in general, $d_\alpha$ is greater than $\dim(H_\alpha)$. However, it is easy to see that the two dimensions agree if and only if $Q_\alpha = \text{id}$. When this is the case for all $\alpha \in \text{Irr}(G)$ we say that $G$ is of Kac type.

Because the coefficients of irreducible representations are dense in $C(G)$, it is enough to understand products of those coefficients to describe the whole $C^*$-algebra structure of $C(G)$. For simplicity, we will assume from now on that for any two irreducible representations $\alpha$ and $\beta$, every irreducible subrepresentation of $\alpha \otimes \beta$ appears with multiplicity one (this assumption will always be satisfied when considering free orthogonal quantum groups). For such a subrepresentation $\gamma$ of $\alpha \otimes \beta$, let $v^\alpha_{\gamma,\beta}$ be an isometric intertwiner from $H_\gamma$ to $H_\alpha \otimes H_\beta$. Then,

$$u^\alpha_{\eta\eta'}u^\beta_{\xi\xi'} = \sum_{\gamma \subseteq \alpha \otimes \beta} u^\gamma_{(\xi \otimes \xi')^{\gamma}} \langle \xi, \xi' \rangle \langle \eta, \eta' \rangle d_\alpha,$$

Note that even though $v^\alpha_{\gamma,\beta}$ is only defined up to a complex number of modulus one, the sesquilinearity of the scalar product ensures that the expression above is independent of this phase. We will also use the projection $P^\alpha_{\gamma,\beta} \in \mathcal{B}(H_{\alpha} \otimes H_{\beta})$ onto the $\gamma$-homogeneous component, $P^\alpha_{\gamma,\beta} = v^\alpha_{\gamma,\beta}v^{\gamma,\beta}_{\eta\eta'}$, which is again independent of the choice of $v^\alpha_{\gamma,\beta}$.

For any $\alpha \in \text{Irr}(G)$, there is a unique (up to unitary equivalence) irreducible representation, called the contragredient representation of $\alpha$ and denoted by $\overline{\alpha}$, such that $\text{Hom}(\varepsilon, \alpha \otimes \overline{\alpha}) \neq \{0\} \neq \text{Hom}(\varepsilon, \overline{\alpha} \otimes \alpha)$, $\varepsilon$ denoting the trivial representation (i.e. the element $1 \otimes 1 \in L^\infty(G) \otimes C$). We choose morphisms $t_\alpha \in \text{Hom}(\varepsilon, \alpha \otimes \overline{\alpha})$ and $s_\alpha \in \text{Hom}(\varepsilon, \overline{\alpha} \otimes \alpha)$ connected by the conjugate equation

$$(\text{id}_\alpha \otimes s_\alpha)^*(t_\alpha \otimes \text{id}_\alpha) = \text{id}_\alpha,$$
and normalized so that \( \|s_\alpha\| = \|t_\alpha\| = \sqrt{\gamma_\alpha} \). Then, \( t_\alpha \) is unique up to a phase and \( s_\alpha \) is determined by \( t_\alpha \).

The morphism \( t_\alpha \) induces a conjugate-linear isomorphism \( j_\alpha : H_\alpha \to H_\pi \) such that, setting \( j_\alpha(\xi) = \overline{\xi} \),

\[
t_\alpha = \sum_{i=1}^{\dim(H_\alpha)} e_i \otimes \overline{e}_i
\]

for any orthonormal basis \((e_i)_i\) of \( H_\alpha \). Note that \( j_\alpha \) need not be a multiple of a conjugate-linear isometry in general — this is however the case if \( G \) is of Kac type. Let us also record the general fact that the map \( \overline{\mu}_\gamma : H_\pi \to H_{\overline{\gamma}} \otimes H_\pi \) defined by

\[
\overline{\xi} \mapsto \Sigma(\xi^{\alpha,\beta}(\xi))^{-\otimes-}
\]

is an isometric morphism from \( \gamma \) to \( \overline{\beta} \otimes \pi \). In particular, when there is no multiplicity in the fusion rules \( \overline{\mu}_\gamma^{\alpha,\beta} \) coincides with \( v_{\gamma,\pi}^{\overline{\beta}} \) up to a complex number of modulus one.

### 2.3. Free orthogonal quantum groups

We will be concerned in the sequel with the free orthogonal quantum groups introduced by S. Wang and A. van Daele in \([23]\) and \([21]\). This subsection is devoted to briefly recalling their definition and main properties.

**Definition 2.6.** For \( N \in \mathbb{N} \), we denote by \( C(O_N^+) \) the universal unital C*-algebra generated by \( N^2 \) self-adjoint elements \((u_{ij})_{1 \leq i,j \leq N}\) such that the matrix \( u = (u_{ij}) \) is unitary. For \( Q \in GL_N(\mathbb{C}) \), we denote by \( C(O_N^+(Q)) \) the unital C*-algebra generated by \( N^2 \) elements \((u_{ij})_{1 \leq i,j \leq N}\) such that the matrix \( u = (u_{ij}) \) is unitary and \( Q\overline{u}Q^{-1} = u \), where \( \overline{u} = (u_{ij}^*) \).

One can check that there is a unique \( * \)-homomorphism \( \Delta : C(O_N^+(Q)) \to C(O_N^+(Q)) \otimes C(O_N^+(Q)) \) such that for all \( i,j \),

\[
\Delta(u_{ij}) = \sum_{i,j=0}^{N} u_{ik} \otimes u_{kj}.
\]

**Definition 2.7.** The pair \( O_N^+ = (C(O_N^+), \Delta) \) is called the *free orthogonal quantum group* of size \( N \). The pair \( O_N^+(Q) = (C(O_N^+(Q)), \Delta) \) is called the *free orthogonal quantum group* of parameter \( Q \).

One can show that the compact quantum group \( O_N^+ \) is of Kac type if and only if \( Q \) is a scalar multiple of a unitary matrix. Although all results of this article apply to general free orthogonal quantum groups of Kac type with \( N \geq 3 \), we will restrict for simplicity to the case of \( O_N^+ \) — see Section 5 for comments about the non-Kac type. The representation theory of free orthogonal quantum groups was computed by T. Banica in \([1]\).

**Theorem 2.8** (Banica). The equivalence classes of irreducible representations of \( O_N^+ \) are indexed by the set of integers \((u^0\) being the trivial representation and \( u^1 = u\) the fundamental one), each one is isomorphic to its contragredient and the tensor product is given inductively by

\[
u^1 \otimes \nu^n = \nu^{n+1} \oplus \nu^{n-1}.
\]

If \( N = 2 \), then \( d_n = n + 1 \). Otherwise,

\[
d_n = \frac{q^{n+1} - q^{-n-1}}{q - q^{-1}},
\]

where \( q + q^{-1} = N \) and \( 0 < q < 1 \). Moreover, \( O_N^+ \) is of Kac type, hence \( d_n = \dim(H_n) \).

There is an elementary estimate on \( d_n \) given by \( q^{-n}(1 - q^2) \leq d_n \leq q^{-n}/(1 - q^2) \). We will use it several times in the sequel without referring to it explicitly.

To be able to do computations, we will use a particular set of representatives of the irreducible representations. More precisely, let \( H_1 = C^N \) be the carrier space of the fundamental representation \( u = u^1 \). Then, for each \( n \in \mathbb{N} \), we let \( H_n \) be the unique subspace of \( H_1^\otimes n \) on which the restriction of \( u \otimes n \) is equivalent to \( u^n \). We denote by \( id_n \) the identity of \( H_n \).

It is easy to check that the map \( t_1 = \sum_{i=1}^{N} e_i \otimes e_i \) satisfies the requirements for the distinguished morphism \( t_u \in \text{Hom}(\varepsilon, u \otimes \pi) \) as defined in the previous subsection, with \( \overline{u} = u \) and \( s_1 = t_1 \). We fix this choice in the rest of the article and we set

\[
t_n = (P_n \otimes P_n)(t_1)_{1,2n}(t_1)_{2,2n-1} \cdots (t_1)_{n,n+1} \in H_n \otimes H_n.
\]
We then have \( s_n = t_n, j_n \circ j_n = \text{id}_{a_n} \), and \( j_n \) is a conjugate linear unitary. The standard trace on \( \mathcal{B}(H_n) \) is given by

\[
\text{Tr}_n(f) = t_n^*(f \otimes \text{id})t_n
\]

and the normalized trace by \( \text{tr}_n(f) = d_n^{-1} \text{Tr}_n(f) \). Moreover, writing again \( \overline{\zeta} = j_n(\zeta) \) for \( \zeta \in H_n \) we have

\[
t_n^*(\zeta \otimes \text{id}_{a_n}) = \overline{\zeta} \quad \text{and} \quad t_n^*(\text{id}_{a_n} \otimes \zeta) = s_n^*(\text{id}_{a_n} \otimes \zeta) = \overline{\zeta}^*.
\]

We will denote by \( P_n \) the orthogonal projection from \( H_n^{\otimes n} \) onto \( H_n \), sometimes called the Jones-Wenzl projection. Note that if \( a + b = n \), then \( P_n(P_a \otimes P_b) = P_n \), so that we may also see \( P_n \) as an element of \( \mathcal{B}(H_a \otimes H_b) \). In other words we have, with the notation of the previous subsection, \( P_n = P_{a,b}^n \) for any \( a, b \) such that \( a + b = n \). The sequence of projections \( (P_n)_{n \in \mathbb{N}} \) satisfies the so-called Wenzl recursion relation (see for instance [14, Eq 3.8] or [20, Eq 7.4]):

\[
P_n = (P_{n-1} \otimes \text{id}_1) + \sum_{l=1}^{n-1} (-1)^{n-l} \frac{d_{n-1}}{d_{n-2}} \left( \text{id}_1^{\otimes (l-1)} \otimes t_1 \otimes \text{id}_1^{\otimes (n-l-1)} \otimes t_1^* \right) (P_{n-1} \otimes \text{id}_1).
\]

We also record the following obvious fact, which will be used frequently in the sequel without explicit reference: for any \( a, b \) we have \( (\text{id}_a \otimes t_1 \otimes \text{id}_b)^* P_{a+b+2} = 0 \). Indeed the image of \( (\text{id}_a \otimes t_1 \otimes \text{id}_b)^* \) is contained in \( H_a \otimes H_b \) which has no component equivalent to \( H_{a+b+2} \). A first application is the following reduced form of the Wenzl relation above, which is actually the original relation presented in [24]:

\[
P_n = (P_{n-1} \otimes \text{id}_1) - \frac{d_{n-2}}{d_{n-1}} (P_{n-1} \otimes \text{id}_1) \left( \text{id}_1^{\otimes (n-2)} \otimes t_1 t_1^* \right) (P_{n-1} \otimes \text{id}_1).
\]

We also have a reflected version as follows:

\[
P_n = (\text{id}_1 \otimes P_{n-1}) - \frac{d_{n-2}}{d_{n-1}} (\text{id}_1 \otimes P_{n-1}) \left( t_1 t_1^* \otimes \text{id}_1^{\otimes (n-2)} \right) (\text{id}_1 \otimes P_{n-1}).
\]

3. Manipulating the Jones-Wenzl projections

In this section we establish two results concerning the sequence of projections \( P_n \) in the representation category of \( O_N^+ \). The first one studies partial traces of these projections, while the second one is a kind of generalization of Wenzl’s recursion relation.

3.1. Partial traces of projections.

The first result we need concerns projections onto irreducible representations that are cut down by a trace. To explain what is going on, let us first consider two integers \( a, b \in \mathbb{N} \). Then, the operator

\[
x_{a,b} = (\text{id}_a \otimes \text{tr}_{b})(P_{a+b}) = d_{a}^{-1}(\text{id}_a \otimes t_a^*)(P_{a+b} \otimes \text{id}_b)(\text{id}_a \otimes t_b) \in \mathcal{B}(H_a)
\]

is a scalar multiple of the identity because it is an intertwiner and \( u^a \) is irreducible. Of course the same holds for \( (\text{tr}_b \otimes \text{id}_a)(P_{a+b}) \in \mathcal{B}(H_a) \). However in general \( x_{a,b,c} = (\text{id}_a \otimes \text{tr}_{b,c})(P_{a+b+c}) \) is not a scalar multiple of the identity. In fact, an easy explicit computation already shows that \( x_{1,1,1} \in \mathcal{B}(H_1 \otimes H_1) \) is a non-trivial linear combination of the identity and the flip map, in particular it is not even an intertwiner. Proposition 3.2 which is the main result of this subsection, shows that when \( b \) tends to \( +\infty \), the partially traced projection \( x_{a,b,c} \) becomes asymptotically scalar.

To prove this, we need a lemma concerning the following construction: for a linear map \( f \in \mathcal{B}(H_k) \), we define its rotated version \( \rho(f) \) by

\[
\rho(f) = (P_k \otimes t_1^*)(\text{id}_1 \otimes f \otimes \text{id}_1)(t_1 \otimes P_k) \in \mathcal{B}(H_k).
\]

Diagrammatically, this transformation is represented as follows:

\[
\begin{array}{c}
\ldots \\
\ldots \\
P_k \\
\ldots \\
\ldots \\
f \\
\ldots \\
P_k \\
\ldots \\
\ldots \\
\end{array}
\]

\[
\rho(f) = \begin{array}{c}
\ldots \\
\ldots \\
\ldots \\
f \\
\ldots \\
\ldots \\
\end{array}
\]

In the sequel, \( \| \cdot \|_{\text{HS}} \) will denote the non-normalized Hilbert-Schmidt norm, i.e. \( \| f \|_{\text{HS}}^2 = \text{Tr}(f^*f) \).
Lemma 3.1. For any $f \in \mathcal{B}(H_k)$, $\text{Tr}(\rho(f)) = (-1)^{k-1} \text{Tr}(f)/d_{k-1}$. Moreover, we have $\|\rho(f)\|_{\text{HS}} \leq \|f\|_{\text{HS}}$.

Proof. For $k = 1$ we have

$$\text{Tr}(\rho(f)) = t_1^*(\text{id}_1^0 \otimes t_1^*)(\text{id}_1^0 \otimes f \otimes \text{id}_1)(\text{id}_1 \otimes t_1 \otimes \text{id}_1)t_1 = t_1^*(f \otimes \text{id}_1)(t_1^* \otimes \text{id}_1^0)(\text{id}_1 \otimes t_1 \otimes \text{id}_1)t_1 = t_1^*(f \otimes \text{id}_1)t_1 = \text{Tr}(f).$$

On diagrams, computing the trace corresponds to connecting upper and lower points pairwise by non-crossing lines on the left or on the right. Representing this by dotted lines for clarity, the computation above can be pictured as follows:

$$\text{Tr}(\rho(f)) = \begin{array}{c}
\begin{array}{c}
\text{Tr} \\
\text{Tr}
\end{array}
\end{array} = \begin{array}{c}
\begin{array}{c}
\text{Tr} \\
\text{Tr}
\end{array}
\end{array} = \text{Tr}(f)$$

When $k \geq 2$, we first perform the transformation

$$\text{Tr}(\rho(f)) = \text{Tr}((P_k \otimes t_1^*)(\text{id}_1 \otimes f \otimes \text{id}_1)(t_1 \otimes \text{id}_1^0)) = \text{Tr}((\text{id}_1^0 \otimes t_1^*)(P_k \otimes \text{id}_1)(\text{id}_1 \otimes f)(t_1 \otimes \text{id}_1^0))$$

which can be diagrammatically represented as follows:

$$\text{Tr}(\rho(f)) = \begin{array}{c}
\begin{array}{c}
\text{Tr} \\
\text{Tr}
\end{array}
\end{array} = \begin{array}{c}
\begin{array}{c}
\text{Tr} \\
\text{Tr}
\end{array}
\end{array} = \text{Tr}(f)$$

Then, we use the adjoint of Wenzl’s formula (\ref{Wenzl}). The term with $P_{k-1} \otimes \text{id}_1$ yields

$$\text{Tr}((\text{id}_1^0 \otimes t_1^*)(P_{k-1} \otimes \text{id}_1^0)(\text{id}_1 \otimes f)(t_1 \otimes \text{id}_1^0)) = \text{Tr}((P_{k-1} \otimes t_1^*)(\text{id}_1 \otimes f)(t_1 \otimes \text{id}_1^0)).$$

This vanishes because the range of $f$ is contained in $H_k$ and $\text{id}_1^0 \otimes t_1^*$ is an intertwiner to $H_1^0 \otimes (k-2)$, which contains no subrepresentation equivalent to $H_k$. The terms from \ref{Wenzl} with $l > 1$ also vanish because $(\text{id}_1 \otimes (l-1) \otimes t_1^* \otimes \text{id}_1^0 \otimes (k-l-1) \otimes t_1 \otimes \text{id}_1)(\text{id}_1 \otimes f) = 0$ for the same reason as before. Hence, we are left with

$$\text{Tr}(\rho(f)) = \frac{(-1)^{k-1}}{d_{k-1}} \text{Tr}((P_{k-1} \otimes t_1^*)(t_1^* \otimes \text{id}_1^0 \otimes (k-2) \otimes t_1 \otimes \text{id}_1)(\text{id}_1 \otimes f)(t_1 \otimes \text{id}_1^0)) = \frac{(-1)^{k-1}}{d_{k-1}} \text{Tr}(f).$$

Here is the diagrammatic computation:

$$\begin{array}{c}
\begin{array}{c}
\text{Tr} \\
\text{Tr}
\end{array}
\end{array} = \begin{array}{c}
\begin{array}{c}
\text{Tr} \\
\text{Tr}
\end{array}
\end{array} = \text{Tr}(f).$$

For the Hilbert-Schmidt norm, we have

$$\text{Tr}(\rho(f)^* \rho(f)) = \text{Tr}(t_1^* \otimes P_k)(\text{id}_1 \otimes f^* \otimes \text{id}_1)(P_k \otimes t_1^*)(\text{id}_1 \otimes f \otimes \text{id}_1)(t_1 \otimes P_k) \leq \text{Tr}((t_1^* \otimes \text{id}_1)(\text{id}_1 \otimes f^* \otimes \text{id}_1)(t_1 \otimes t_1^*) \text{id}_1^0 \otimes (k-2) \otimes t_1^*)(\text{id}_1 \otimes f \otimes \text{id}_1)(t_1 \otimes \text{id}_1^0))$$

$$= \text{Tr}((t_1^* \otimes \text{id}_1^0 \otimes (k-1) \otimes t_1^*)(\text{id}_1 \otimes f^* \otimes \text{id}_1^0)(t_1 \otimes t_1^* \otimes \text{id}_1)(\text{id}_1 \otimes f \otimes \text{id}_1^0)(t_1 \otimes \text{id}_1^0 \otimes t_1)) \leq \text{Tr}(f^* f).$$
Proposition 3.2. Assume that $N > 2$. Let $a, b, c \in \mathbb{N}$ and consider the operator

$$x_{a,b,c} = (\text{id}_a \otimes \text{tr}_b \otimes \text{id}_c)(P_{a+b+c}) : H_a \otimes H_c \to H_a \otimes H_c.$$ 

Then, there exist two constants $\lambda_{a,c} > 0$ and $D_{a,c} > 0$ depending only on $N, a$ and $c$ such that

$$\|x_{a,b,c} - \lambda_{a,c}(\text{id}_a \otimes \text{id}_c)\| \leq D_{a,c}q^b.$$ 

In particular $x_{a,b,c} \to \lambda_{a,c}(\text{id}_a \otimes \text{id}_c)$ as $b \to \infty$.

Proof. For convenience, the proof will be done with the non-normalized trace, and hence we consider the non-normalized operator $X_{a,b,c} = (\text{id}_a \otimes \text{Tr}_b \otimes \text{id}_c)(P_{a+b+c}) = dbx_{a,b,c}$. We first observe that

$$(\text{Tr}_a \otimes \text{Tr}_c)(X_{a,b,c}) = \text{Tr}(P_{a+b+c}) = da_{a+b+c} = dbq^{-a-c} + O(q^b)$$

and accordingly set

$$\lambda_{a,c} = q^{-a-c}/da_d$$

With this notation, we have $\text{Tr}(X'_{a,b,c}) = O(q^b)$ and we want to show that $\|X'_{a,b,c}\| \leq D_{a,c}$. We will prove that

$$\|\text{Tr}_a \otimes \text{Tr}_c(X'_{a,b,c})\| \leq D_{a,c}\|f\|_{\text{HS}}$$

for any $f \in \mathcal{B}(H_a \otimes H_c)$. Moreover any such $f$ can be decomposed into a multiple of the identity and a map with zero trace, and since the estimate is satisfied for $f = \text{id}$ by our choice of $\lambda_{a,c}$ we can assume $(\text{Tr}_a \otimes \text{Tr}_c)(f) = 0$. Eventually, we note that in this case $(\text{Tr}_a \otimes \text{Tr}_c)(X'_{a,b,c}) = (\text{Tr}_a \otimes \text{Tr}_c)(X_{a,b,c}f)$.

Now we observe that $(\text{Tr}_a \otimes \text{Tr}_c)(X_{a,b,c}f) = \text{Tr}(P_{a+b+c}f_{13})$ where $\text{Tr}$ is the trace of $H_1^{(a+b+c)}$, and we use Wenzl’s formula \(\Box\) to write

$$\text{Tr}(X_{a,b,c}f) = \text{Tr}((P_{a+b+c-1} \otimes \text{id}_1)f_{13})$$

Moreover, one can factor $P_a \otimes P_b \otimes P_c$ out of the right side of $(P_{a+b+c-1} \otimes \text{id}_1)f_{13}$. Since $P_k(\text{id} \otimes t_1 \otimes \text{id}) = 0$ on $H_1^{\otimes (k-2)}$, we see that $(P_a \otimes P_b \otimes P_c)(\text{id}_1^{(a+b+c-1)} \otimes t_1 \otimes \text{id}_1^{(a+b+c-1)}) = 0$ if $l \neq a$ and $l \neq a+b$. Hence there are only three terms to bound in the expression above.

The first term is equal to

$$\text{Tr}((P_{a+b+c-1} \otimes \text{id}_1)f_{13}) = \text{Tr}(X_{a,b,c-1}f^b),$$

where $f^b = (\text{id}_a \otimes \text{id}_c-1 \otimes \text{Tr}_1)(f)$ satisfies $\text{Tr}(f^b) = 0$ and $\|f^b\|_{\text{HS}} \leq \sqrt{a_1\|f\|_{\text{HS}}}$. For $l = a$, we use the trivial bound

$$\frac{d_{a-1}}{d_{a+b+c-1}} \times \|f_{13}\|_{\text{HS}} \times \|t_1\|^2 \times \|P_{a+b+c-1} \otimes \text{id}_1\|_{\text{HS}} = \left(\frac{d_{a-1}^2}{d_{a+b+c-1}}\right)\|f\|_{\text{HS}}.$$
where \( f^t = (\text{id}_a \otimes \rho)(f) \) satisfies \( \text{Tr}(f^t) = 0 \) and \( \|f^t\|_{\text{HS}} \leq \|f\|_{\text{HS}} \) by Lemma 5.1. Here is the diagrammatic version of the previous computation,

\[
\begin{aligned}
\text{Tr}(X_{a,b,c} f) &\leq \text{Tr}(X_{a,b,c-1} f^\psi) + \frac{d_{a+b-1}}{d_{a+b+c-1}} \text{Tr}(X_{a,b-1,c} f^t) + \frac{d_1^{3/2} d_{a-1} \sqrt{d_b}}{d_{a+b+c-1}} \|f\|_{\text{HS}}.
\end{aligned}
\]

We recognize indeed \( \rho(f_{(2)}) \) in the last diagram. The projections \( P_c \) included in the definition of \( \rho(f_{(2)}) \) do not appear on the diagram since they are absorbed by \( P_{a+b+c-1} \) (through the trace for one of them), but they must be taken into account. Summing up, we have

\[
|\text{Tr}(X_{a,b,c} f)| \leq |\text{Tr}(X_{a,b,c-1} f^\psi)| + \frac{d_{a+b-1}}{d_{a+b+c-1}} |\text{Tr}(X_{a,b-1,c} f^t)| + \frac{d_1^{3/2} d_{a-1} \sqrt{d_b}}{d_{a+b+c-1}} \|f\|_{\text{HS}}.
\]

We will now proceed by induction on \( c \) with the following induction hypothesis

\( H(c) \): "for all \( a \in \mathbb{N} \) there exists a constant \( D_{a,c} \) such that for all \( b \in \mathbb{N} \) and all \( f \in \mathcal{B}(H_a \otimes H_c) \) satisfying \( \text{Tr}(f) = 0 \) we have \( |\text{Tr}(X_{a,b,c} f)| \leq D_{a,c} \|f\|_{\text{HS}} \).

Recall that \( H(0) \) holds with \( D_{a,c} = 0 \) because \( X_{a,b,0} \) is an intertwiner, hence a multiple of the identity.

Now we take \( c > 0 \), we assume that \( H(c-1) \) holds and we apply it to the first term in the right-hand side of Equation (3). Since \( \|f^\psi\|_{\text{HS}} \leq \sqrt{d_1} \|f\|_{\text{HS}} \) and \( d_b \leq d_{a+b+c-1} \), this yields

\[
|\text{Tr}(X_{a,b,c} f)| \leq \left( \sqrt{d_1} D_{a,c-1} + d_1^{3/2} d_{a-1} \right) \|f\|_{\text{HS}} + \frac{d_{a+b-1}}{d_{a+b+c-1}} |\text{Tr}(X_{a,b-1,c} f^t)|.
\]

We set \( D' = \max(\sqrt{d_1} D_{a,c-1} + d_1^{3/2} d_{a-1}, \sqrt{d_{a+c}}) \) and we iterate the inequality above over \( b \). Noticing that

\[
|\text{Tr}(X_{a,0,c} f^{2b})| \leq \sqrt{d_1} \|f^{2b}\|_{\text{HS}} \leq D' \|f^{2b}\|_{\text{HS}}
\]

this yields, with the convention that the product equals 1 for \( l = 0 \):

\[
|\text{Tr}(X_{a,b,c} f)| \leq D' \sum_{l=0}^b \|f^l\| \left( \prod_{t=b-l+1} d_{a+t+c-1} \right).
\]

Using the inequality \( \|f^l\|_{\text{HS}} \leq \|f\|_{\text{HS}}^l \), as well as the estimate \( d_x/d_y \leq q^{y-x} \) for \( x < y \) and the fact that \( |q| < 1 \) if \( N > 2 \), we see that \( H(c) \) holds:

\[
|\text{Tr}(X_{a,b,c} f)| \leq D' \|f\|_{\text{HS}} \sum_{l=0}^b q^{lc} \leq D' \|f\|_{\text{HS}} \sum_{l=0}^\infty q^{lc}.
\]

\( \square \)

It is clear from the beginning of the proof that the Proposition 3.2 has the following equivalent formulation, which we will use for the proof of Theorem 4.3.

**Corollary 3.3.** Assume that \( N > 2 \). For any \( a, c \in \mathbb{N} \) and any \( f \in \mathcal{B}(H_a \otimes H_c) \) such that \( \text{Tr}(f) = 0 \), there exists a constant \( D_{a,c} \) such that we have, for any \( b \in \mathbb{N} \):

\[
|\text{Tr}(P_{a+b+c} f_{13})| \leq D_{a,c} \|f\|_{\text{HS}}.
\]
3.2. A variation on Wenzl’s recursion formula. The second result can be called a "higher weight" version of Wenzl’s recursion formula [5]. As a matter of fact, let \( \zeta = \sum \zeta^{(1)} \otimes \zeta^{(2)} \) be a vector in \( H_2 \subset H_1 \otimes H_1 \). Then, the map \( f = \sum \zeta^{(2)} \zeta^{(1)\ast} \in \mathcal{B}(H_1) \) has trace 0, so that applying \( \text{Tr}_1(f \cdot) \otimes \text{id}_{n-1} \) to both sides of Equation (5) yields

\[
\sum (\zeta^{(1)} \otimes \text{id}_{n-1}) P_n(\zeta^{(2)} \otimes \text{id}_{n-1}) = - \frac{d_{n-2}}{d_{n-1}} \sum P_{n-1}(\zeta^{(1)} \zeta^{(2)\ast} \otimes \text{id}_{n-2}) P_{n-1}.
\]

What we are going to prove is a similar equality but with \( \zeta \) being any highest weight vector, i.e. \( \zeta \in H_{p+q} \subset H_p \otimes H_q \) for arbitrary \( p \) and \( q \).

**Lemma 3.4.** Let \( \zeta \in H_{p+q} \) be decomposed as \( \zeta = \sum \zeta^{(1)} \otimes \zeta^{(2)} \in H_p \otimes H_q \) and \( \zeta = \sum \zeta^{(1)} \otimes \zeta^{(2)} \in H_q \otimes H_p \). For all \( p \geq n \geq q \), there exist \( \alpha^p_{n,q} \in \mathbb{C} \) such that

(7) \[
\sum (\zeta^{(1)} \otimes \text{id}_{n-p}) P_n(\zeta^{(2)} \otimes \text{id}_{n-q}) = \alpha^p_{n,q} \sum P_{n-p}(\zeta^{(1)} \zeta^{(2)\ast} \otimes \text{id}_{n-p-q}) P_{n-q}
\]

(8) \[
\sum (\text{id}_{n-p} \otimes \zeta^{(1)\ast}) P_n(\text{id}_{n-q} \otimes \zeta^{(2)}) = \alpha^p_{n,q} \sum P_{n-p}(\text{id}_{n-p-q} \otimes \zeta^{(1)} \zeta^{(2)\ast} P_{n-q}.
\]

Moreover, there exist constants \( C_{p,q} > 0 \) such that for all \( n \in \mathbb{N} \), \( C_{p,q} \leq |\alpha^p_{n,q}| \leq 1 \).

**Proof.** Let us first note that the second equality follows from the first one by conjugation, hence we will only focus on the first one. If \( p = 0 \), then

\[
P_n(\zeta^{(2)} \otimes \text{id}_{n-q}) = P_n(\zeta^{(2)} \otimes \text{id}_{n-q}) P_{n-q} = P_n(\zeta^{(1)} \otimes \text{id}_{n-q}) P_{n-q}
\]

and the result is proved with \( \alpha^0_{n,0} = 1 \) for all \( n \). Similarly, the result holds for \( q = 0 \) with \( \alpha^p_{0,0} = 1 \). We will proceed by induction on \( p \) and \( q \) with the induction hypothesis

\( H_N : " \text{For any } p, q \text{ with } p + q \leq N, \text{ there exists a constant } C_{p,q} > 0 \text{ such that for all } n \geq p + q, \text{ there exists a constant } \alpha^p_{n,q} \text{ such that Equations (7) and (8) hold and } C_{p,q} \leq |\alpha^p_{n,q}| \leq 1."

As we have seen, \( H_0 \) and \( H_1 \) hold, so let us assume \( H_N \) and consider \( p, q \geq 1 \) such that \( p + q = N + 1 \). In order to use the induction hypothesis, we refine the decompositions of \( \zeta \) in the following way:

\[
\zeta^{(1)} = \sum \zeta^{(11)} \otimes \zeta^{(12)} \in H_{p-1} \otimes H_1,
\]

\( \zeta^{(1)} = \sum \zeta^{(1)} \otimes \zeta^{(1)} \in H_1 \otimes H_{p-1}, \)

\( \zeta^{(2)} = \sum \zeta^{(21)} \otimes \zeta^{(22)} \in H_1 \otimes H_{q-1}, \)

\( \zeta^{(2)} = \sum \zeta^{(21)} \otimes \zeta^{(2)} \in H_q \otimes H_{1}. \)

Applying the map \( \sum (\zeta^{(1)} \otimes \text{id}_{n-p})(\cdot)(\zeta^{(2)} \otimes \text{id}_{n-q}) \) to Wenzl’s formula (5), the first term on the right-hand side reads

\[
\sum (\zeta^{(12)} \otimes \zeta^{(11)} \ast \otimes \text{id}_{n-p})(\text{id} \otimes P_{n-1}) (\zeta^{(21)} \otimes \zeta^{(22)} \otimes \text{id}_{n-q})
\]

\[= \sum (\zeta^{(12)} \ast \zeta^{(21)})(\zeta^{(11)} \ast \otimes \text{id}_{n-p}) P_{n-1} (\zeta^{(22)} \ast \text{id}_{n-q}).
\]

Consider the linear map \( T : H_p \otimes H_q \rightarrow \mathcal{B}(H_{n-q} \otimes H_{n-p}) \) defined by \( T(x \otimes y) = (x \otimes \text{id}_{n-p}) P_{n-1} (y \otimes \text{id}_{n-q}) \). Then, the term above equals

\[
T \left( \sum \zeta^{(12)} \ast \zeta^{(21)}(\zeta^{(11)} \otimes \zeta^{(22)}) \right) = T \left( (\text{id}_{p-1} \otimes t^* \otimes \text{id}_{q-1})(\zeta) \right).
\]

The argument of \( T \) on the right-hand side vanishes because \( \zeta \) is a highest weight vector, so that the whole term vanishes. Coming back to (5) and setting \( L = \sum (\zeta^{(1)} \ast \otimes \text{id}_{n-p}) P_n (\zeta^{(2)} \otimes \text{id}_{n-q}) \), we thus have

\[
L = - \frac{d_{n-2}}{d_{n-1}} \sum (\zeta^{(1)} \ast \otimes \text{id}_{n-p})(\text{id} \otimes P_{n-1})(t_1 t_1^* \otimes \text{id}_{n-2})(\text{id} \otimes P_{n-1})(\zeta^{(2)} \otimes \text{id}_{n-q})
\]

\[= - \frac{d_{n-2}}{d_{n-1}} \sum (\zeta^{(1)} \ast \otimes \text{id}_{n-p})(P_{n-1})(\zeta^{(12)} \ast \otimes \text{id}_{n-1})(t_1 t_1^* \otimes \text{id}_{n-2})(\zeta^{(21)} \otimes \text{id}_{n-1}) P_{n-1} (\zeta^{(22)} \otimes \text{id}_{n-q}).
\]
Now we apply $H_N$ to $\zeta^{(1)}$ (with $p' = p - 1$, $q' = 1$) and to $\zeta^{(2)}$ (with $p' = 1$, $q' = q - 1$) to get
\[
L = -\frac{d_{n-2}}{d_{n-1}}\alpha_p^{n-1}\alpha_{q-1}^{n-1} \sum (P_{n-p}(\zeta^{(1)}(1) \otimes \text{id}_{n-p-1})P_{n-p-1}(\zeta^{(2)}(1) \otimes \text{id}_{n-q-1})P_{n-q}).
\]
The last step is to apply again the induction hypothesis. To do this, we need to refine once more our decomposition by setting
\[
\zeta = \sum \eta^{(1)} \otimes \eta^{(2)} \otimes \eta^{(3)} \in H_1 \otimes H_{p+q-2} \otimes H_1
\]
\[
\eta^{(2)} = \sum \eta^{(21)} \otimes \eta^{(22)} \in H_{p-1} \otimes H_{q-1}
\]
\[
\eta^{(2)} = \sum \eta^{(2)} \otimes \eta^{(2)} \in H_{q-1} \otimes H_{p-1}.
\]
Note that in the above computations we can replace everywhere $\zeta^{(1)}$, $\zeta^{(1)}$, $\zeta^{(2)}$ and $\zeta^{(2)}$ respectively by $\eta^{(1)}$, $\eta^{(21)}$, $\eta^{(22)}$ and $\eta^{(3)}$. Thus, applying $H_N$ to $\eta^{(2)}$ (with $p' = p - 1$, $q' = q - 1$) yields
\[
L = -\frac{d_{n-2}}{d_{n-1}}\alpha_p^{n-1}\alpha_{q-1}^{n-1} \sum P_{n-p}(\eta^{(1)} \otimes \text{id}_{n-p-1})
\]
\[
P_{n-p-1}(\eta^{(2)} \otimes \text{id}_{n-p-q})P_{n-q-1}(\eta^{(3)} \otimes \text{id}_{n-q-1})P_{n-q}
\]
\[
= -\frac{d_{n-2}}{d_{n-1}}\alpha_p^{n-1}\alpha_{q-1}^{n-1} \sum P_{n-p}(\eta^{(1)} \otimes \eta^{(2)} \otimes \eta^{(3)} \otimes \text{id}_{n-p-q})P_{n-q}
\]
\[
= -\frac{d_{n-2}}{d_{n-1}}\alpha_p^{n-1}\alpha_{q-1}^{n-1} \sum P_{n-p}(\zeta^{(1)} \otimes \text{id}_{p-1})P_{n-q}.
\]
This proves Equation (7) for $p$ and $q$ and as mentioned at the beginning of the proof, Equation (8) follows by conjugation. Moreover, we see that
\[
|\alpha_p^{n}| \geq \frac{d_{n-2}}{d_{n-1}}C_{p-1,1}C_{q-1,1} \geq \frac{1}{d_1}C_{p-1,1}C_{q-1,1} > 0
\]
hence $H_{N+1}$ holds and the proof is complete. \qed

4. The key estimate

We now turn to the main technical result of this article, Theorem 4.3, which concerns the behavior of the scalar product $\langle \chi \eta, u^n \chi \eta' \rangle$ as $n$ tends to $+\infty$. Its proof will span the whole of this section.

We start by recalling two technical lemmata from the literature on free orthogonal quantum groups. The first one gives a norm estimate for some explicit intertwiners in tensor products of irreducible representations. For any four integers $l$, $k$, $m$ and $a$ such that $k + l = m + 2a$, the map
\[
(\gamma_{l,k}^m)^* = P_m(\text{id}_{l-a} \otimes t_a^* \otimes \text{id}_{k-a})
\]
is an intertwiner from $H_l \otimes H_k$ to $H_m$, hence there is a scalar $\kappa_m^{l,k}$ such that $\gamma_{l,k}^m = \kappa_m^{l,k} V_{l,k}^m$ is an isometric intertwiner. The scalar $\kappa_m^{l,k}$ can be explicitly computed, see [22]. However, we will only need the following consequence of this computation.

Lemma 4.1. There exists a constant $B_a$, depending only on $a$ and $N$, such that for all $k$, $l$ and $m = k + l - 2a$ we have $|\kappa_m^{l,k}| \leq B_a$.

Proof. This is a consequence of the estimates given in [22, Lem 4.8], see also [9]. The sequence $(B_a)_a$ diverges exponentially as $q^{-a/2}$. \qed

We will also need the following estimates which were already used in [20] and [9].

Lemma 4.2. Let $x$, $y$ and $z$ be integers and let $\mu \neq x + y + z$ be a subrepresentation of both $x \otimes (y + z)$ and $(x + y) \otimes z$. Then, there exists a constant $A > 0$ depending only on $N$ such that
\[
\|(id_x \otimes P_{y+z})(P_{x+y} \otimes id_z) - P_{x+y+z}\| \leq Aq^y\text{ and } \|P_{x+y+z}P_{x+y+z}\| \leq Aq^y.
\]
Proof. The first inequation is \([20, \text{Lem A.4}]\). For the second one, note that \(P^{x+y+z}_\mu P_{x+y+z} = 0 = P_{x+y+z} P^{x+y+z}_\mu\) because \(\mu\) is not the highest weight. Thus, we have

\[
\|P^{x+y+z}_\mu P_{x+y+z}\| = \|P^{x+y+z}_\mu ((id_x \otimes P_y)(P_x \otimes id_z)) - P_{x+y+z}\| P^{x+y+z}_\mu \| \\
\leq \|P^{x+y+z}_\mu\| ((id_x \otimes P_y)(P_x \otimes id_z)) - P_{x+y+z}\| P^{x+y+z}_\mu \| \\
\leq \|(id_x \otimes P_y)(P_x \otimes id_z)) - P_{x+y+z}\| \|P^{x+y+z}_\mu\| \\
\leq Aq^q.
\]

We now state and prove an estimate, as \(l, l'\) tend to \(+\infty\), about the scalar product between products of the characters \(\chi_l, \chi_{l'}\) with coefficients of fixed representations. Since \(\chi_l, \chi_{l'}\) have norm 1 in the GNS space \(L^2(\mathbb{G})\), it is clear that these scalar products are bounded when \(l, l'\) tend to \(+\infty\). However one can do much better:

**Theorem 4.3.** Assume that \(N > 2\). Let \(k, n\) be integers, let \(\xi, \eta \in H_n\) be orthogonal unit vectors and let \(\xi', \eta' \in H_k\) be arbitrary unit vectors. Then, there exists \(K > 0\) such that we have, for all integers \(l, l'\):

\[
\left| \left< \chi_l u^l_{\xi,\eta}, u^n_{\xi',\eta'} \right> \right| \leq K q^{\max(l, l')}.
\]

In particular \(\left| \left< \chi_l u^l_{\xi,\eta}, u^n_{\xi',\eta'} \right> \right| \to 0\) when \(l\) or \(l'\) tends to \(+\infty\).

**Proof.** The proof will consist of the following steps:

1. computation of the scalar product as a sum \(S = \sum S_m\) in the category of representations,
2. simplification of \(S_m\) into \(T_m\),
3. expression of \(T_m\) as a trace,
4. application of Lemma 3.4 to reduce the trace,
5. application of Proposition 3.2 to estimate the trace,
6. backtracking of all approximations.

**Step 1.** We compute the products and the scalar product using the formulæ given in Subsection 2.2

\[
S = \left< \chi_l u^l_{\xi,\eta}, u^n_{\xi',\eta'} \right> = \sum_{i=1}^{d_l} \sum_{j=1}^{d_n} \left< u^l_{\xi,\eta} u^l_{\xi',\eta'}, u^n_{\xi',\eta'} \right>
\]

\[
= \sum_{i=1}^{d_l} \sum_{j=1}^{d_n} \sum_{m=0}^{+\infty} \left< u^m_{\xi,\eta} (\xi \otimes \eta'), v^m_{\xi',\eta'} (\xi \otimes \eta) \right> \left< v^m_{\xi',\eta'} (\xi \otimes \eta), v^m_{\xi,\eta} (\xi \otimes \eta') \right>
\]

\[
= \sum_{i=1}^{d_l} \sum_{j=1}^{d_n} \sum_{m=0}^{+\infty} \left< v^m_{\xi,\eta} (\xi \otimes \eta'), v^m_{\xi',\eta'} (\xi \otimes \eta) \right> \left< v^m_{\xi',\eta'} (\xi \otimes \eta), v^m_{\xi,\eta} (\xi \otimes \eta') \right>
\]

\[
= \sum_{i=1}^{d_l} \sum_{j=1}^{d_n} \sum_{m=0}^{+\infty} \left< v^m_{\xi,\eta} (\xi \otimes \eta'), v^m_{\xi',\eta'} (\xi \otimes \eta) \right> \left< v^m_{\xi',\eta'} (\xi \otimes \eta), v^m_{\xi,\eta} (\xi \otimes \eta') \right>
\]

\[
= \sum_{m=0}^{+\infty} \left< v^m_{\xi,\eta} (\xi \otimes \eta'), v^m_{\xi',\eta'} (\xi \otimes \eta) \right> \left< v^m_{\xi',\eta'} (\xi \otimes \eta), v^m_{\xi,\eta} (\xi \otimes \eta') \right>.
\]

Let us denote by \(S^m\) the \(m\)-th term in brackets in (9) and note that it can only be non-zero if \(u^m\) is a subrepresentation of both \(u^l \otimes u^l\) and \(u^n \otimes u^n\). This means that there are integers \(a\) and \(b\) such that

\[
l + k = m + 2a\text{ and } n + l' = m + 2b.
\]
Note that \( l - n + b - a = l' - k + a - b \) and let us denote by \( c \) this number. To estimate \( S^m \), we will use the explicit formula for the intertwiners given just before Lemma 4.1:

\[
\left(v_{m,k}^{l,k}\right)^* = \kappa_m^{kl} P_m(\text{id}_{l-a} \otimes t_a^* \otimes \text{id}_{k-a}), \quad \left(v_{m}^{k,l}\right)^* = \kappa_m^{kl} P_m(\text{id}_{k-a} \otimes t_a^* \otimes \text{id}_{l-a}),
\]

\[
\left(v_{m,n}^{l',n}\right)^* = \kappa_m^{nl'} P_m(\text{id}_{l'-b} \otimes t_b^* \otimes \text{id}_{n-b}), \quad \left(v_{m}^{n,l'}\right)^* = \kappa_m^{nl'} P_m(\text{id}_{n-b} \otimes t_b^* \otimes \text{id}_{l'-b}).
\]

so that (4) becomes:

\[
S^m = (\kappa_m^{kl} \kappa_m^{nl'})^2 \left( (P_m \otimes P_m)(\text{id}_{l-a} \otimes t_a^* \otimes \text{id}_{k-a} \otimes t_a^* \otimes \text{id}_{l-a}) (\Sigma \otimes \Sigma)(\xi' \otimes t_l \otimes \eta'), (P_m \otimes P_m)(\text{id}_{n-b} \otimes t_b^* \otimes \text{id}_{l'-b} \otimes t_b^* \otimes \text{id}_{n-b}) (\xi \otimes t_{l'} \otimes \eta) \right).
\]

**Step 2.** Let us set, for \( 0 \leq \mu, \mu' \leq m \),

\[
S_{m,\mu,\mu'}^m = \left( (P_{\mu}^{l-a,k-a} \otimes P_{\mu'}^{l-a,1-a})(\text{id}_{l-a} \otimes t_a^* \otimes \text{id}_{k-a} \otimes t_a^* \otimes \text{id}_{l-a}) (\Sigma \otimes \Sigma)(\xi' \otimes t_l \otimes \eta'), (P_{\mu'}^{n-b,l'-b} \otimes P_{\mu}^{n-b,1-b})(\text{id}_{n-b} \otimes t_b^* \otimes \text{id}_{l'-b} \otimes t_b^* \otimes \text{id}_{n-b}) (\xi \otimes t_{l'} \otimes \eta) \right)
\]

so that \( S^m = (\kappa_m^{kl} \kappa_m^{nl'})^2 S_{m,m} \). If \( \mu \) or \( \mu' \) is strictly less than \( m \), then we know by Lemma 4.2 that there is a constant \( A \) depending only on \( N \) such that either

\[
\left\| P_{\mu}^{l-a,k-a} P_{\mu'}^{n-b,l'-b} \right\| \leq A q^{l-a-(n-b)} \text{ or } \left\| P_{\mu}^{l-a,1-a} P_{\mu'}^{n-b,1-b} \right\| \leq A q^{l-a-(n-b)}.
\]

This gives the bound \( |S_{m,\mu,\mu'}^m| \leq A ||t_l|| ||t_{l'}|| ||t_a||^2 ||t_b||^2 q^c = A \sqrt{dt} \sqrt{dt'} d_{a} d_{b} q^c \) which will be used in the end to estimate \( S^m \). Let us expand back the vectors \( t_l = \sum e_t^l \otimes \tau_t^l \) and \( t_{l'} = \sum e_t^{l'} \otimes \tau_t^{l'} \) and introduce

\[
T_m = \sum_{t=1}^{d_t} \sum_{s=1}^{d_s} \left( (\text{id}_{l-a} \otimes t_a^* \otimes \text{id}_{k-a} \otimes t_a^* \otimes \text{id}_{l-a}) (e_t^l \otimes \xi' \otimes \eta' \otimes \tau_t^l), (\text{id}_{n-b} \otimes t_b^* \otimes \text{id}_{l'-b} \otimes t_b^* \otimes \text{id}_{n-b}) (\xi \otimes e_t^{l'} \otimes \tau_t^{l'} \otimes \eta) \right)
\]

so that \( S^m = (\kappa_m^{kl} \kappa_m^{nl'})^2 (T_m - \sum S_{m,\mu,\mu'}^m) \), where the sum runs over all \( (\mu, \mu') \neq (m, m) \).

**Step 3.** The problem is now to estimate \( T_m \), using the following tensor decomposition of the vectors \( \xi, \eta, \xi' \) and \( \eta' \) in Sweedler’s notation:

\[
\xi = \sum \xi_{(1)} \otimes \xi_{(2)} \in H_{n-b} \otimes H_b,
\eta = \sum \eta_{(1)} \otimes \eta_{(2)} \in H_{n-b} \otimes H_b,
\xi' = \sum \xi'_{(1)} \otimes \xi'_{(2)} \in H_{a} \otimes H_{k-a},
\eta' = \sum \eta'_{(1)} \otimes \eta'_{(2)} \in H_{a} \otimes H_{k-a}.
\]
Because \( t'_a(x \otimes \eta) = y^s(x) \), we get

\[
T^m = \sum_{t=1}^{d_t} \sum_{l=1}^{d_l} \sum_{s=1}^{d_s} \left\langle \left( \mathbf{id}_{l-a} \otimes \xi_{(1)}^* \right) \left( e'_{(1)} \otimes \xi_{(2)}^* \otimes (\eta_{(1)}^* \otimes \mathbf{id}_{l-a}) \right) (\tau'_s) \right. , \left. \mathbf{id}_{l-b} \otimes \eta_{(2)}^* \right) (\tau'_s) \otimes \eta_{(1)} \right\rangle.
\]

\[
\xi_{(1)} \otimes \left( \tilde{\xi}_{(2)}^* \otimes \mathbf{id}_{l-b} \right) (e'_{(1)}) \otimes \left( \mathbf{id}_{l-b} \otimes \eta_{(2)}^* \right) (\tau'_s) \otimes \eta_{(1)} \right\rangle,
\]

\[
\tilde{\xi}_{(2)} \otimes \mathbf{id}_{l-b} \otimes \tilde{\xi}_{(2)}^* (e'_{(1)}) \otimes \left( \mathbf{id}_{l-b} \otimes \eta_{(2)}^* \right) (\tau'_s) \otimes \eta_{(1)} \right\rangle.
\]

The properties of conjugate vectors imply that

\[
\left\langle \left( \eta_{(1)}^* \otimes \mathbf{id}_c \otimes \tilde{\xi}_{(1)}^* \right) (\tau'_s), \left( \tilde{\xi}_{(2)}^* \otimes \mathbf{id}_c \otimes \tilde{\xi}_{(2)}^* \right) (\tau'_s) \right\rangle = \left\langle \left( \tilde{\xi}_{(2)} \otimes \mathbf{id}_c \otimes \tilde{\xi}_{(2)}^* \right) (\tau'_s), \left( \mathbf{id}_c \otimes \tilde{\xi}_{(2)}^* \right) (\tau'_s) \right\rangle.
\]

Making this change in the last expression of \( T^m \) and using the fact that \( \sum \langle x, S e'_s \rangle \langle T e'_s, y \rangle = \langle x, S P_t T^* y \rangle \) enables to simplify the sum over \( s \), we obtain

\[
T^m = \sum_{t=1}^{d_t} \sum_{l=1}^{d_l} \sum_{s=1}^{d_s} \left\langle \left( \xi_{(1)}^* \otimes \mathbf{id}_c \otimes \tilde{\xi}_{(1)}^* \right) (e'_{(1)}), \left( \tilde{\xi}_{(2)} \otimes \mathbf{id}_c \otimes \tilde{\xi}_{(2)}^* \right) (e'_{(2)}), \mathbf{id}_c \otimes \eta_{(2)}^* \right\rangle \left( \eta_{(1)}^* \otimes \mathbf{id}_c \otimes \tilde{\xi}_{(1)}^* \right) (e'_{(1)})
\]

\[
= \sum \text{Tr}_{\otimes l} \left( P_l \left( \xi_{(1)}^* \otimes \mathbf{id}_c \otimes \tilde{\xi}_{(1)}^* \right) (e'_{(1)}), \left( \tilde{\xi}_{(2)} \otimes \mathbf{id}_c \otimes \tilde{\xi}_{(2)}^* \right) (e'_{(2)}), \mathbf{id}_c \otimes \eta_{(2)}^* \right) \left( \eta_{(1)}^* \otimes \mathbf{id}_c \otimes \tilde{\xi}_{(1)}^* \right) (e'_{(1)})
\]

where \( \text{Tr}_{\otimes l} \) denotes the non-normalized trace on \( H^G_{(l)} \).

**Step 4.** We cannot apply Corollary 5.3 to \( T^m \) because there are two highest weight projections instead of one. We will therefore use Lemma 5.4 to reduce the problem to a case where Corollary 5.3 applies. Let us first simplify the notation by setting

\[
f = \sum \xi_{(1)} \tilde{\xi}_{(2)} : H_b \to H_{n-b},
\]

\[
g = \sum \eta_{(2)} \eta_{(1)} : H_{n-b} \to H_b,
\]

\[
f' = \sum \xi_{(1)} \tilde{\xi}_{(2)} : H_{k-a} \to H_a,
\]

\[
g' = \sum \eta_{(2)} \eta_{(1)} : H_a \to H_{k-a}.
\]

By Lemma 4.2, \( \| (\mathbf{id}_b \otimes P_{l-b})(P_{l-k+a} \otimes \mathbf{id}_{k-a}) - P_l \| \leq Aq^c \) and \( \| (P_{l-a} \otimes \mathbf{id}_a)(\mathbf{id}_{l-b} \otimes P_{l-n-b}) - P_l \| \leq Aq^c \), so that it is enough to study

\[
Y^m = \text{Tr}_{\otimes l} \left[ \left( \eta_{(2)} \eta_{(1)} \right) (\mathbf{id}_a \otimes \mathbf{id}_c \otimes \mathbf{id}_{l-a}) (f \otimes \mathbf{id}_c \otimes f') \right.
\]

\[
\left. \left( \mathbf{id}_b \otimes P_{l-b} \right)(P_{l-k+a} \otimes \mathbf{id}_{k-a}) (g \otimes \mathbf{id}_c \otimes g') \right] = \text{Tr}_{\otimes l} \left[ \left( \eta_{(2)} \eta_{(1)} \right) (f \otimes \mathbf{id}_c \otimes f') (\mathbf{id}_a \otimes \mathbf{id}_c \otimes \mathbf{id}_{l-a}) (g \otimes \mathbf{id}_c \otimes g') \right.
\]

\[
\left. \left( \mathbf{id}_b \otimes P_{l-k+a} \otimes \mathbf{id}_{l-b} \right)(P_{l-k+a} \otimes \mathbf{id}_{l-b}) (f \otimes \mathbf{id}_c \otimes f') \right] \left( \mathbf{id}_b \otimes \mathbf{id}_c \otimes \mathbf{id}_{l-a} \right),(g \otimes \mathbf{id}_c \otimes g') (P_{l-k+a} \otimes \mathbf{id}_{l-a}) (f \otimes \mathbf{id}_c \otimes f') \right] \left( \mathbf{id}_b \otimes \mathbf{id}_c \otimes \mathbf{id}_{l-a} \right)
\]

\[
\left. \left( \mathbf{id}_b \otimes P_{l-k+a} \otimes \mathbf{id}_{l-b} \right)(P_{l-k+a} \otimes \mathbf{id}_{l-b}) (f \otimes \mathbf{id}_c \otimes f') \right] \left( \mathbf{id}_b \otimes \mathbf{id}_c \otimes \mathbf{id}_{l-a} \right)
\]

We now apply Lemma 5.4 to \( f' \) (with \( p = k-a \) and \( q = a \)) and \( g \) (with \( p = n-b \) and \( q = b \)):

\[
P_{l-n+b}(\mathbf{id}_c \otimes f'') P_{l-b} = \sum (\alpha_{k-a,b}^{r-a-b})^{-1} (\mathbf{id}_{l-n-b} \otimes \xi_{(1)}^*) P_{l-a} (\mathbf{id}_{l-b} \otimes \tilde{\xi}_{(2)}^*)
\]

\[
P_{l-k+a}(g \otimes \mathbf{id}_c) P_{l-a} = \sum (\alpha_{n-b,b}^{r-a-b})^{-1} (\eta_{(2)}^* \otimes \mathbf{id}_{l-k+a}) P_{l-b} (\mathbf{id}_{l-a} \otimes \tilde{\xi}_{(1)}^*)
\]
where \( \xi' = \sum \xi^{(1)} \otimes \xi^{(2)} \in H_{k-a} \otimes H_a \) and \( \eta = \sum \eta^{(1)} \otimes \eta^{(2)} \in H_b \otimes H_{n-b} \). This yields

\[
Y^m = \beta \sum \text{Tr}_{\otimes l-n+2b} \left[ (\text{id}_{l-n+2b} \otimes \xi^{(1)*}) (\text{id}_b \otimes P_{l+a-b}) (\text{id}_{l-k+a} \otimes g') (\eta^{(2)*} \otimes \text{id}_{l-k+2a}) (P_{l+b-a} \otimes \text{id}_a) (\text{id}_{l+n-b}) (f \otimes \text{id}_{l+n-b}) \right]
\]

\[
= \beta \sum \text{Tr}_{\otimes l-n+2b} \left[ (\xi^{(1)*} \otimes \text{id}_{l-k+2a}) (\text{id}_n \otimes P_{l+a-b}) (P_{l+b-a} \otimes \text{id}_k) (\text{id}_{l+n-b} \otimes g' \otimes \xi^{(2)}) \right]
\]

\[
= \beta \text{Tr}_{\otimes c+k+n} \left[ (\text{id}_n \otimes P_{l+a-b}) (P_{l+b-a} \otimes \text{id}_k) (f \otimes \text{id}_c \otimes g' \otimes \tilde{f}') \right]
\]

where \( \beta = \left( a_{l-a,b}^t \cdot a_{n-b,b}^t \right)^{-1} \) and

\[
\tilde{f}' = \sum \xi^{(2)} \xi^{(1)*} : H_{k-a} \to H_a,
\]

\[
\tilde{g} = \sum \eta^{(1)} \eta^{(2)*} : H_{n-b} \to H_b.
\]

To conclude the computation, we use again Lemma 42 to get the following bound:

\[
\| (\text{id}_n \otimes P_{l+a-b}) (P_{l+b-a} \otimes \text{id}_k) - P_{l+k+b-a} \| \leq A q^\epsilon,
\]

enabling us to eventually reduce the problem to the study of

\[
Z^m = \beta \text{Tr}_{\otimes c+k+n} \left[ P_{l+k+b-a} (\tilde{g} \otimes f \otimes \text{id}_c \otimes g' \otimes \tilde{f}') \right].
\]

**Step 5.** We will now apply Corollary 3.3. The orthogonality assumption in the statement of the present theorem can by rephrased as the vanishing of trace required for Corollary 3.3. We have indeed

\[
\text{Tr}(P_n(\tilde{g} \otimes f)) = \text{Tr}_{n-b} \otimes \text{Tr}_b \left[ P_n((\text{id}_b \otimes \eta^*) (t_b \otimes \text{id}_{n-b}) \otimes (\text{id}_{n-b} \otimes t_b^*) (\xi \otimes \text{id}_b)) \right]
\]

\[
= \text{Tr}_{n-b} \left[ (\text{id}_{n-b} \otimes t_b^*) (P_n \otimes \text{id}_b) \right]
\]

\[
(\text{id}_b \otimes \eta^*) (t_b \otimes \text{id}_{n-b}) \otimes (\text{id}_{n-b} \otimes t_b^*) (\xi \otimes \text{id}_b) \otimes \text{id}_b (\text{id}_{n-b} \otimes t_b) \]

\[
= \text{Tr}_{n-b} \left[ (\text{id}_{n-b} \otimes t_b^*) (P_n \otimes \text{id}_b) \right]
\]

\[
(\text{id}_b \otimes \eta^*) (t_b \otimes \text{id}_{n-b}) \otimes (\text{id}_{n-b} \otimes t_b^*) (\xi \otimes \text{id}_b) \otimes \text{id}_b (\text{id}_{n-b} \otimes t_b) \]

\[
= \text{Tr}_{n-b} \left[ (\text{id}_{n-b} \otimes t_b^*) (P_n \otimes \text{id}_b) \right]
\]

\[
(\text{id}_b \otimes \eta^*) (t_b \otimes \text{id}_{n-b}) \otimes (\text{id}_{n-b} \otimes t_b^*) (\xi \otimes \text{id}_b) \otimes \text{id}_b (\text{id}_{n-b} \otimes t_b) \]

\[
= \text{Tr}_{n-b} \left[ (\text{id}_{n-b} \otimes t_b^*) (P_n \otimes \text{id}_b) \right]
\]

\[
(\text{id}_b \otimes \eta^*) (t_b \otimes \text{id}_{n-b}) \otimes (\text{id}_{n-b} \otimes t_b^*) (\xi \otimes \text{id}_b) \otimes \text{id}_b (\text{id}_{n-b} \otimes t_b) \]

\[
= \text{Tr}_{n-b} \left[ (\text{id}_{n-b} \otimes t_b^*) (P_n \otimes \text{id}_b) \right]
\]

\[
(\text{id}_b \otimes \eta^*) (t_b \otimes \text{id}_{n-b}) \otimes (\text{id}_{n-b} \otimes t_b^*) (\xi \otimes \text{id}_b) \otimes \text{id}_b (\text{id}_{n-b} \otimes t_b) \]

\[
= \text{Tr}_{n-b} \left[ (\text{id}_{n-b} \otimes t_b^*) (P_n \otimes \text{id}_b) \right]
\]

\[
(\text{id}_b \otimes \eta^*) (t_b \otimes \text{id}_{n-b}) \otimes (\text{id}_{n-b} \otimes t_b^*) (\xi \otimes \text{id}_b) \otimes \text{id}_b (\text{id}_{n-b} \otimes t_b) \]

Since the only intertwiner from \( H_n \otimes H_n \) to \( C \), up to a scalar, is \( \tilde{g} \otimes \xi \mapsto t_n^* (\tilde{g} \otimes \xi) = \langle \xi, \eta \rangle \), this shows that \( \text{Tr}(P_n(\tilde{g} \otimes f)) = 0 \). Besides, we have the estimate

\[
\| P_n(\tilde{g} \otimes f) \|_{HS} \leq \| \tilde{g} \otimes f \|_{HS} = \| \xi \| \| \eta \| = 1
\]

and similarly \( \| P_k(g' \otimes \tilde{f}') \|_{HS} \leq 1 \). Thus, Corollary 3.3 applies to \( F = P_n(\tilde{g} \otimes f) P_n \otimes P_k(g' \otimes \tilde{f}') P_k \) and yields \( |Z^m| \leq \beta D_{n,k} \).

**Step 6.** Now we can rewind the successive approximations to bound \( S^m \). In the remainder of this proof, the symbols \( K_i \) will denote numbers possibly depending on \( n \) and \( k \), but not on \( m \), \( l \), and \( l' \). Recall that \( a, b, c \) are defined in terms of \( m, l \), and \( l' \). To bound \( T^m - Z^m \), we use the rough estimate \( |\text{Tr}_H(X)| \leq \dim(H) \| X \| \) which holds for any Hilbert space \( H \) and any \( X \in B(H) \). Let us note that the operator norms of \( f, g, f', g' \) are dominated by their Hilbert-Schmidt norms, which are equal to 1. However, the space over which we take the trace is \( H_{l+1}^{2 \beta} \), which is too big. We therefore take advantage of the projections inside the trace to restrict to \( H_b \otimes H_{l-b} \) and \( H_{l+1} \otimes H_{n-l-1} \) when passing from \( T^m \) to \( Y^m \) and to \( H_n \otimes H_{l+1-b} \) when passing from \( Y^m \) to \( Z^m \). This yields:

\[
|T^m| \leq |Y^m - Y^m| + |Y^m - Z^m| + |Z^m| \leq A(d_b d_{l-b} + d_{l-a} + \beta d_{n+l+a-b}) q^c + \beta D_{n,k}.
\]
By the second part of Lemma 3.4, $\beta D_{n,k}$ is bounded by $C_{k-a,1}^{-1} C_{n-b,1}^{-1} D_{n,k}$. Because $a \leq k$ and $b \leq n$ take only a finite number of values when $n$ and $k$ are fixed, all these constants can be bounded by a constant $K_0$. We can also bound the coefficient of $q^t$ by

$$A(d_n d_{l'} + d_k d_l + \beta d_n d_{l'+k}) \leq K_1 q^{-\max(l,l')}.$$  

Secondly, we have to consider the sum of the $|S_{n,n'}|^t$'s for $(n,m)$. Note that this term is non-zero only if $n$ and $m$ are subrepresentations respectively of $(l-a) \otimes (k-a)$ and $(n-b) \otimes (l-b)$. Thus, there are at most $\min(n-b, l-b) \leq kn$ such terms and each of them is bounded by $A\sqrt{\pi'}^t \sqrt{\pi'}^{t'} q^c$, as explained at the beginning of the proof. Also recall from Lemma 3.1 that $\kappa^{kl}_{m,n}$ and $\kappa^{nl}_{m,n}$ are respectively bounded by $B_a$ and $B_b$, and since $a, b$ take only a finite number of values (determined by $k$ and $n$), they are bounded by a constant $K_2$. Summing up, we have

$$|S_{n,m}| \leq K_2^t |T^t| + K_2^t k n d_k d_n A \sqrt{\pi'}^t \sqrt{\pi'}^{t'} q^c \leq K_2^t K_3 q^{-\max(l,l')} + K_2^t K_3 q^{c - \max(l,l')}.$$  

Let $t = \min(n + a - b, k + b - a)$. Then, $c \geq \max(l,l') - t$ and thus we have proved that $|S_{n,m}|$ is bounded by a constant $K_4$ independent of $m$, $l$ and $l'$. To obtain our estimate for $S$, we now have to sum the $S_{n,m}$'s. Note that for $S_{n,m}$ to be non-zero, $m = k + l - 2a = n + l' - 2b$ must be a subrepresentation of both $l \otimes k$ and $n \otimes l'$. There are at most $\min(k,n)$ such $m$'s and they moreover satisfy $m \geq \max(l-k, l'-n)$, so that $d_m \geq K_5 q^{-\max(l,l')}$ and we can write

$$|S| \leq \sum_{m=0}^{\infty} \frac{1}{d_m} |S_{n,m}| \leq \min(k,n) K_5 q^{\max(l,l')} K_4.$$  

5. THE RADIAL SUBALGEBRA

We are now ready to prove the announced results on the radial subalgebra. Before going into the proofs, we recall the definition of this subalgebra as well as some of its basic properties.

**Definition 5.1.** For any finite-dimensional representation $\nu$ of a compact quantum group $G$, the **character** of $\nu$ is the element $\chi_\nu = (\text{id} \otimes \text{Tr}) (\nu) \in C(G)$. This element depends only on the equivalence class of $\nu$.

The **radial subalgebra** $A \subset L^\infty (O_N^+) \subset C^*$ is the von Neumann subalgebra generated by the fundamental character $\chi_\nu = \chi_u$, where $u$ is the matrix of generators.

Note that the radial subalgebra was also used as a sub-$C^*$-algebra $A_f$ of the full $C^*$-algebra $C(O_N^+)$ by M. Brannan in [1]. The spectrum of $\chi_\nu$ in $C(O_N^+)$ is $[-N,N]$, whereas it is $[-2,2]$ in $C_{\text{red}}(O_N^+)$ and $L^\infty (O_N^+)$. In the full case, the evaluation functionals $e_t : A_f \to \mathbb{C}$ at $t \in [-N,N]$ induce completely positive maps $T_t : L^\infty (O_N^+) \to L^\infty (O_N^+)$ which approximate the identity as $t \to N$. This allowed M. Brannan to prove that $L^\infty (O_N^+)$ has the Haagerup approximation property.

The terminology is justified by the following analogy with the "classical case" of the free group factors $\mathcal{L}(F_N)$. More precisely, denote the standard generators of $F_N$ by $a_i$ and consider

$$u = \text{diag}(a_1, \ldots, a_N, a_1^{-1}, \ldots, a_N^{-1}) \in \mathcal{L}(F_N) \otimes \mathcal{B}(\mathbb{C}^{2N}).$$

This is indeed a representation of the compact quantum group dual to $F_N$. We put $\chi_\nu = \sum_{i=1}^{N} (a_i + a_i^{-1}) \in \mathcal{L}(F_N)$ and we define the radial subalgebra $A \subset \mathcal{L}(F_N)$ as the von Neumann subalgebra generated by $\chi_\nu$. If we consider, for $x \in \mathcal{L}(F_N)$ and $g \in \mathcal{F}_N$, the coefficient $x_g = \langle x, g \rangle = \tau(g^* x)$ with respect to the standard trace $\tau$, then $x$ belongs to $A$ if and only if the function $(g \mapsto x_g)$ is radial, i.e. $x_g$ only depends on the word length of $g$.

The fusion rules of $O_N^+$ imply that $\chi_{1, n} = \chi_n \chi_1 = \chi_{n+1} + \delta_{n>0} \chi_{n-1}$, so that the radial subalgebra is abelian and generated as a weakly closed subspace by the characters $(\chi_n)_{n \in \mathbb{N}}$. Moreover, it was proved in [1] that the spectrum of $\chi_1$ in $L^\infty (O_N^+)$ is $[-2,2]$ and that the restriction of the Haar state is the semi-circle law. More precisely, one can identify $A$ with $L^\infty([-2,2])$ via the functional calculus $f \mapsto f(\chi_1)$ and the scalar product induced by the Haar state is computed via

$$\langle f(\chi_1), g(\chi_1) \rangle = \frac{1}{2\pi} \int_{-2}^{2} f(s) g(s) \sqrt{4 - s^2} ds.$$
In particular, the radial subalgebra is diffuse. The characters $\chi_n$ correspond to dilated Chebyshev polynomials of the second kind: $\chi_n(X) = T_n(X) = U_n(X/2)$ where $T_0 = 1$, $T_1 = X$ and $T_{n} = T_{n+1} + T_{n-1}$ if $n \geq 1$.

Since $L^\infty(\mathcal{O}_{\mathbb{C}}^{\mathbb{C}})$ is a finite von Neumann algebra, there is a unique $h$-preserving conditional expectation $E : M \to A$, which is explicitly given by

$$ E(u^n_{\xi\eta}) = \frac{\langle \xi, \eta \rangle}{d_n} \chi_n. \tag{10} $$

We shall denote by $A^+$ the subspace $\{ z \in M, E(z) = 0 \}$, which by Equation (10) is the weak closure of the linear span of coefficients $u^n_{\xi\eta}$ with $\langle \xi, \eta \rangle = 0$.

As mentioned in the preliminaries, all the results of this article apply in fact to general free orthogonal quantum groups $O^+(Q)$ of Kac type, i.e. such that $Q$ is a scalar multiple of a unitary matrix. The situation for non-Kac type free orthogonal quantum groups is however quite different. First recall that $L^\infty(O^+(Q))$ is in that case a type III factor, at least for some values of the parameter $Q$ (see [20]). More precisely the Haar state has then a non-trivial modular group, which is given on the generating matrix $u \in L^\infty(\mathbb{G}) \otimes \mathcal{B}(\mathbb{C}^N)$ by

$$ \sigma_t \otimes \text{id}(u) = (\text{id} \otimes \text{e}^it(Q^*Q)^{-t}u)(\text{id} \otimes \text{e}^it(Q^*Q)^{-it}), $$

where we assume $Q$ to be normalized so that $\text{Tr}(Q^*Q) = \text{Tr}(Q^*Q)^{-1}$. In particular, it is clear that $\sigma_t(\chi_1)$ does not belong to $A$ for all $t$ unless $Q^*Q \in C_{\mathbb{N}}$, and this implies that there exists no $h$-invariant conditional expectation onto $A$ in the non-Kac case. It might even be that there exists no normal conditional expectation onto $A$ at all. On the other hand, as far as we know all the available tools for the study of abelian subalgebras require the presence of a conditional expectation.

Let us also comment on the $N = 2$ case, where the tools developed in the previous section break down. If we restrict to Kac type free orthogonal quantum groups, there are only two examples at $N = 2$ up to isomorphism, namely $SU(2)$ and $SU_{-1}(2)$. In the first case $C(SU(2))$ is commutative so that $A$ is clearly not maximal abelian, and in fact $A$ is not maximal abelian either in the second case — this is easily seen by embedding $C(SU_{-1}(2))$ into $C(S^3)$ as in [23].

With the estimate of Theorem 4.3 we can investigate the structure of the radial subalgebra. In fact, all the proofs are quite straightforward using techniques which are well-known to experts in von Neumann algebras. We however chose to give detailed proof both for convenience of the reader and for the sake of completeness. From now on, we will write $M = L^\infty(\mathcal{O}_{\mathbb{C}}^{\mathbb{C}})$ and $A = \{ \chi_1 \}''$.

### 5.1. Maximal abelianness

We first prove that $A$ is maximal abelian. This will follow from the following lemma concerning unitary sequences in $A$, which relies itself on Theorem 4.3. In fact here we only use the fact that $|\langle \chi_1 u^n_{\xi\eta}, u^n_{\xi\eta} \chi_{l'} \rangle| \to 0$ as $l, l' \to \infty$ if $\xi$ is orthogonal to $\eta$.

**Lemma 5.2.** Let $N \geq 3$. Let $(u_i)_i$ be a sequence of unitaries in $A$ weakly converging to $0$ and let $z \in A^+$. Then, $u_i z u_i^*$ converges $*$-weakly to $0$.

**Proof.** For any $i$, let us decompose $u_i$ as $u_i = \sum_{l=0}^{+\infty} a^l_i \chi_l$ and note that by unitarity, $\|a^l_i\|_2 = 1$. Assume for the moment that $z$ is of the form $u^n_{\xi\eta}$ for some integer $n$ and two orthogonal unit vectors $\xi, \eta \in H_n$.

Considering another integer $k$ and two arbitrary unit vectors $\xi', \eta' \in H_k$, we will first prove that

$$ S_i = |\langle u^n_{\xi\eta}, u^n_{\xi'\eta'} u_i^* \rangle| = \left| \sum_{l,l'=0}^{+\infty} a^l_i a^{l'} \langle u^n_{\xi\eta}, \chi_l u^n_{\xi'\eta'} \chi_{l'} \rangle \right| \xrightarrow{i \to +\infty} 0. $$

Let $\epsilon > 0$ and note that $\langle u^n_{\xi\eta}, \chi_l u^n_{\xi'\eta'} \rangle = \langle \chi_l u^n_{\xi'\eta'}, u^n_{\xi\eta} \chi_{l'} \rangle$. By Theorem 4.3 there exists $L \in \mathbb{N}$ such that $|\langle \chi_l u^n_{\xi'\eta'}, u^n_{\xi\eta} \chi_{l'} \rangle| \leq \epsilon/2$ as soon as $l, l' > L$. Thus,

$$ S_i \leq \sum_{l,l'=0}^{L} |a^l_i a^{l'}| |\langle u^n_{\xi\eta}, \chi_l u^n_{\xi'\eta'} \chi_{l'} \rangle| + \frac{\epsilon}{2} \sum_{l,l'=L+1}^{+\infty} |a^l_i a^{l'}| \leq \sum_{l,l'=0}^{L} |a^l_i a^{l'}| |\langle u^n_{\xi\eta}, \chi_l u^n_{\xi'\eta'} \chi_{l'} \rangle| + \frac{\epsilon}{2} \|a^l_i\|_2^2.$$
Now, because $u_i \to 0$ in the weak topology, $a^l_i = h(\chi u_i) \to 0$ for all fixed $l \in \mathbb{N}$ as $i \to +\infty$. In particular, there exists $i_0 \in \mathbb{N}$ such that for all $i > i_0$ and all $l, l' \leq L$, 

$$|a^l_i u_i| \leq \frac{\epsilon}{2} \left( \sum_{i=0}^{L} (u^k_{i'} u_i \chi l u^m_{i} \chi r) \right)^{-1}.$$ 

Thus, for $i > i_0$, $|\langle u^k_{i'} u_i, u_i u^m_{i} u^r_i \rangle| \leq \epsilon$ and $S_i \to 0$.

Making finite linear combinations on the left-hand side, we see that $\langle t, u_i u^m_{i} u^r_i \rangle$ tends to $0$ as $i \to \infty$ for any $t \in \text{Pol}(O^+_N)$. Since $\text{Pol}(O^+_N)$ is dense in $L^2(O^+_N)$ and $(u_i u^m_{i} u^r_i)$ is bounded $L^2(O^+_N)$, this is also true for any $t \in L^\infty(O^+_N) \subseteq L^2(O^+_N)$. Then, we can write $\langle t, u_i u^m_{i} u^r_i \rangle = \langle u_i u^m_{i} u^r_i \rangle$ and use similarly the density of $A^1 \cap \text{Pol}(O^+_N)$ in $A^1$ for the norm of $L^2(O^+_N)$. This shows that $\langle t, u_i z u^r_i \rangle = \langle u^r_i u_i z, z \rangle \to 0$ as $i \to \infty$ for any $t \in M$ and $z \in A^1$. Since $h$ is a faithful trace and $(u_i z u^r_i)$ is bounded in $L^\infty(O^+_N)$, this shows the stated $*$-weak convergence. 

**Theorem 5.3.** Let $N \geq 3$. Then, the radial subalgebra $A$ is maximal abelian in $M$.

**Proof.** Let $x \in A' \cap M$ and consider the decomposition $x = y + z$ with $y \in A$ and $z \in A^1$. Note that 

$$x = u_i x u^r_i = u_i y u_i^r + u_i z u^r_i = y + u_i z u^r_i,$$

so that Lemma 5.2 yields $x = y + \lim_i u_i z u^r_i = y$. 

The argument above also proves that the $C^*$-algebra generated by $\chi$ is maximal abelian in the reduced $C^*$-algebra $C_{\text{red}}(O^+_N)$. From the theorem, following the strategy of [17], one can also recover the factoriality of $L^\infty(O^+_N)$ established in [20] and also in [9] (as a byproduct of non-inner amenability).

**Corollary 5.4.** For $N \geq 3$, the von Neumann algebra $L^\infty(O^+_N)$ is a factor.

**Proof.** We exploit the natural action of the classical group $O_N$ on $M$ given by the following formula, for $g \in O_N$ and $x \in C_{\text{red}}(O^+_N)$:

$$\alpha_g(x) = (\text{ev}_g \pi \otimes \text{id}) \Delta'(x),$$

where $\pi : C(O^+_N) \to C(O_N)$ is the canonical quotient map, $\text{ev}_g : C(O_N) \to \mathbb{C}$ is the evaluation map at $g$, and $\Delta' : C_{\text{red}}(O^+_N) \to C(O^+_N) \otimes C_{\text{red}}(O^+_N)$ is induced from the coproduct of $C(O^+_N)$ thanks to Fell’s absorption principle. The $*$-automorphism of $C_{\text{red}}(O^+_N)$ defined in this way leaves the Haar state $h$ invariant, and thus it extends to $M$. The action of $\alpha_g$ on coefficients of an irreducible representation $u^n$ of $O^+_N$ is given by the following expression, where $u^n = (\pi \otimes \text{id}) (u^n)$ is the restriction of $u^n$ to $O_N$:

$$(\alpha_g \otimes \text{id}) (u^n) = (\text{ev}_g \otimes \text{id} \otimes \text{id}) (v^n_{\nu}) = ((1 \oplus u^n(g))) u^n.$$ 

In particular we have $\alpha_g(\chi) = \sum_{r,s} v^n_{r,s} u^n_{r,s}$, where $r, s$ are indices corresponding to an orthonormal basis of $H_n$. Note that $\alpha_g$ leaves the subspace of coefficients of any fixed representation of $O^+_N$ invariant.

Since $A$ is maximal abelian in $M$, $\alpha_g(A)$ is maximal abelian in $M$ for every $g \in O_N$, and so the center of $M$ is contained in $\alpha_g(A)$ for every $g \in O_N$. Hence it suffices to show that the intersection of the subalgebras $\alpha_g(A)$ reduces to $C_1$. Equivalently, we take $c \in A$ such that $\alpha_g(c) \in A$ for all $g \in O_N$, and we want to prove that $c = \lambda 1$. For this we write $c = \sum c_n \chi_n$ in $L^2(O^+_N)$. The orthogonal projection of $\alpha_g(c)$ onto the subspace generated by the coefficients of $u^n$ is $c_n \alpha_g(\chi_n)$, whereas the projection of $A$ is $C_\chi_n$. Hence, if $c_n \neq 0$ then we must have $\alpha_g(\chi_n) = C_\chi_n$ for all $g \in O_N$. By the computation above and the fact that the coefficients $u^n_{r,s}$ are linearly independent, this happens if and only if $v^n(g)$ is scalar for all $g$, i.e. $v^n$ is a multiple of a one-dimensional representation. But then $v^{2n} \subset v^n \otimes v^n$ would be trivial, and if $n > 0$ this would imply that $O_N$ has only finitely many irreducible representations up to equivalence, since any of them is contained in one of the $v^n$ and $v^{n+1} \subset v^n \otimes v^n$. Hence $c_n = 0$ for all $n > 0$. 

**5.2. Singularity and the mixing property.** Now that we know that the radial subalgebra is a MASA, we can investigate further properties. By [12], we know that $A$ cannot be a regular MASA (also called Cartan subalgebra) because $M$ is strongly solid. In view of this result and of the case of the radial MASA in free group factors treated in [16], it is natural to conjecture that $A$ is singular. Recall that for a von Neumann algebra $N$, we denote by $\mathcal{U}(N)$ the group of unitary elements of $N$.

**Definition 5.5.** A MASA $A \subset M$ is said to be singular if $\{1 \in \mathcal{U}(M), uA u^* \subset A \} = \mathcal{U}(A)$. 

There are several ways of proving that a MASA is singular. One way goes through a von Neumann algebraic analogue of the mixing property for group actions, called weak mixing, which eventually turns out to be equivalent to singularity. In our case, we can prove a stronger statement than singularity, namely that $A$ is mixing in the following sense:

**Definition 5.6.** A subalgebra $A$ of a von Neumann algebra $M$ is said to be mixing if for any sequence $(u_n)_n$ of unitaries in $A$ converging weakly to $0$ and any elements $x, y \in A^\perp$,

\[ \|E_A(xu_ny)\|_2 \to 0. \]

Again, the proof is an easy application of Theorem 4.3.

**Theorem 5.7.** For $N \geq 3$ the radial MASA is mixing.

**Proof.** Fix a sequence of unitaries $u_i \in A$ converging weakly to $0$. Let $k, n \in \mathbb{N}$ and consider two pairs of orthogonal unit vectors $\xi, \eta \in H_n$ and $\xi', \eta' \in H_k$. Since elements of the form $u_i^{k_n} \xi$ (resp. $u_i^{n_k} \eta$) with $\xi' \perp \eta'$ (resp. $\xi \perp \eta$) span a dense subspace of $A^\perp \subset L^2(O_n^+)$, it is enough to prove that $X_i \to 0$, where

\[ X_i = \|E(u_i^{k_n} u_i^{n_k})\|_2. \]

To compute the square norm, we can use the orthonormal basis given by the characters to get

\[ X_i = \sum_{l' = 0}^{+\infty} \left( \sum_{l = 0}^{+\infty} |\langle \chi_l u_i^{k_n} u_i^{n_k} \xi, \chi_{l'} \eta \rangle|^2 \right)^2 \]

\[ = \sum_{l' = 0}^{+\infty} \left( \sum_{l = 0}^{+\infty} |\langle \chi_l u_i^{k_n} u_i^{n_k} \xi, \chi_{l'} \eta \rangle|^2 \right) \]

\[ = \sum_{l' = 0}^{+\infty} |\langle u_i^{k_n} u_i^{n_k} \xi, \chi_{l'} \eta \rangle|^2. \]

Since $u_i$ converges weakly to $0$, each term of the sum above tends to $0$ as $i \to \infty$. Hence it suffices to show that the dominated convergence theorem applies. For this we decompose the unitaries $u_i$ according to the basis of characters: $u_i = \sum_{i = 0}^{+\infty} a_i^l \chi_l$, with $\sum_i |a_i^l|^2 = \|u_i\|_2 = 1$. Then, the Cauchy-Schwartz inequality and Theorem 4.3 yield

\[ X_i = \sum_{l' = 0}^{+\infty} \sum_{l = 0}^{+\infty} a_i^l |\langle \chi_l u_i^{k_n} u_i^{n_k} \xi, \chi_{l'} \eta \rangle|^2 \]

\[ \leq \sum_{l' = 0}^{+\infty} \sum_{l = 0}^{+\infty} |\langle \chi_l u_i^{k_n} u_i^{n_k} \xi, \chi_{l'} \eta \rangle|^2 \]

\[ \leq K \sum_{l' = 0}^{+\infty} \sum_{l = 0}^{+\infty} q^\max(l, l') < +\infty. \]

**Corollary 5.8.** The radial MASA is singular.

**Proof.** Since $A$ is diffuse, we can find a sequence of unitaries $u_n \in A$ converging weakly to $0$. Let $v \in U(M)$ be a unitary such that $vAv^* \subset A$. In particular we have $u_n v^* \in A$, hence $\|E_A(u_n^* u_n v^*)\|_2 = \|u_n^* v u_n v^*\|_2 = 1$. On the other hand the mixingness property implies that $\|E_A(u_n^* v u_n v^*) - E_A(v) E_A(v^*)\|_2 \to 0$. As a result we have $1 = \|E_A(v) E_A(v^*)\|_2 \leq \|E_A(v)\|_2 \leq \|v\|_2 = 1$, hence $E_A(v) = v$ and $v \in A$.

5.3. **The spectral measure.** Another very natural problem for a given MASA is to study the $A$-$A$-bimodule structure of $H = L^2(M) \oplus L^2(A)$. This can be done through the associated spectral measure. Because the representations of $A$ on $H$ on the left and on the right commute, their images generate an abelian von Neumann subalgebra of $B(H)$ isomorphic to $L^\infty([-2, 2] \times [-2, 2])$. Thus, disintegrating $H$ with respect to this subalgebra yields a measure class $[\nu]$ on $[-2, 2 \times [-2, 2]$ which encapsulates some properties of the bimodule.
We first recall an elementary lemma about the Chebyshev polynomials $U_n$, which are linked to the characters $\chi_n$ by $\chi_n = T_n(\chi_1) = U_n(\chi_1/2)$:

**Lemma 5.9.** For all $n \in \mathbb{N}$ we have $\sup_{t \in [-1,1]} |U_n(t)| = n + 1$. Moreover, for all $r > 1$ there exists an open neighborhood $\Omega$ of $[-1,1]$ in $\mathbb{C}$ such that $\sup_{z \in \Omega} |U_n(z)| < (n + 1)r^n$ for all $n$.

**Proof.** The first assertion is well known and follows immediately from the formula

$$U_n(\cos \theta) = \frac{\sin((n + 1)\theta)}{\sin(\theta)} = \sum_{k=0}^{n} \phi^{(n-2k)}\theta.$$ 

The second assertion is probably also known. Let us denote $\phi(w) = \frac{1}{2}(w + w^{-1})$ for $w \in \mathbb{C}^*$. By the identity theorem we have $U_n(\phi(w)) = \sum_{k=0}^{n} w^{n-2k}$ hence $|U_n(\phi(w))| < (n + 1)|w|^n$ if $|w| > 1$.

On the other hand one can compute $\phi(se^{i\theta}) = \frac{1}{2}(s + s^{-1})\cos(\theta) + \frac{i}{2}(s - s^{-1})\sin(\theta)$, hence for $s \geq 1$ the image by $\phi$ of the circle $C_s = \{ w \in \mathbb{C} \mid |w| = s \}$ is the ellipse $E_s$ with axes $\frac{1}{2}[-s - s^{-1}, s + s^{-1}]$ and $\frac{i}{2}[-s + s^{-1}, -s - s^{-1}]$. Note that when $s$ decreases to 1, $\frac{1}{2}(s + s^{-1})$ (resp. $\frac{i}{2}(s - s^{-1})$) decreases to 1 (resp. 0). In particular one sees that for $r > 1$ the image $\Omega = \phi(D_r)$ of $D_r = \{ w \in \mathbb{C} \mid 1 \leq |w| < r \}$ is an open neighborhood of $[-1,1]$. For $z \in \Omega$ one obtains then $|U_n(z)| < (n + 1)r^n$ by writing $z = \phi(w)$ with $w \in D_r$.

**Theorem 5.10.** For $N \geq 3$ the measure $\nu$ is Lebesgue equivalent to $\lambda \otimes \lambda$, where $\lambda$ denotes the Lebesgue measure on $[-2,2]$.

**Proof.** We will follow the strategy of [8]. Let us first look at some "projections" of $\nu$ in the following sense: for two integers $k$ and $n$ and two pairs of orthogonal unit vectors $\xi, \eta \in H_n$ and $\xi', \eta' \in H_k$, there exists a complex measure $\mu$ on $[-2,2] \times [-2,2]$ such that for any $a, b \in A$,

$$\langle au^k_{\xi',\eta'}, bu^\mu_{\xi,\eta} \rangle = \int_{-2}^{2} \int_{-2}^{2} a(s)b(t)d\mu(s,t).$$

We will compute the Radon-Nikodym derivative of $\mu$ with respect to $\lambda \otimes \lambda$. To do this, let us set

$$D_{l,l'} = \langle \chi_l u^k_{\xi',\eta'} \chi_l', u^\mu_{\xi,\eta} \rangle$$

$$f(z, z') = \sum_{l,l'=0}^{\infty} A_{l,l'}(z, z') \text{ where } A_{l,l'}(z, z') = T_l(z)T_{l'}(z')D_{l,l'}.$$ 

Now we fix $r \in \{1, 1/\sqrt{2}\}$ and we consider the open subset $[-1,1] \subset \Omega \subset \mathbb{C}$ given by Lemma 5.9. Theorem 4.3 yields the following estimate for the supremum norm on $2\Omega \times 2\Omega$:

$$\|A_{l,l'}\|_\infty \leq K\|T_l\|_\infty\|T_{l'}\|_\infty q^{\max\{l,l'\}} \leq K(l + 1)r^{l}q^{l/2}(l' + 1)r^{l'}q^{l'/2}.$$ 

This implies that the series of functions defining $f$ converges normally on $2\Omega \times 2\Omega$. Since all summands are polynomials $f$ is holomorphic on $2\Omega \times 2\Omega$ and in particular analytic on $[-2,2] \times [-2,2]$.

The function $f$ is linked to the measure $\mu$ by the following computation:

$$\langle au^k_{\xi',\eta'} \times b, u^\mu_{\xi,\eta} \rangle = \sum_{l,l'=0}^{\infty} \langle a, \chi_l \rangle \langle b, \chi_{l'} \rangle \langle \chi_l u^k_{\xi',\eta'} \chi_{l'}, u^\mu_{\xi,\eta} \rangle = \sum_{l,l'=0}^{\infty} \langle a, \chi_l \rangle \langle b, \chi_{l'} \rangle D_{l,l'}$$

$$= \frac{1}{4\pi^2} \sum_{l,l'=0}^{\infty} D_{l,l'} \left( \int_{-2}^{2} a(s)T_l(s)\sqrt{4 - s^2}ds \right) \left( \int_{-2}^{2} b(t)T_{l'}(t)\sqrt{4 - t^2}dt \right)$$

$$= \frac{1}{4\pi^2} \int_{-2}^{2} \int_{-2}^{2} a(s)b(t)f(s,t)\sqrt{4 - s^2}\sqrt{4 - t^2}d\mu(\lambda \otimes \lambda)(s,t).$$

Hence, $f(s,t)\sqrt{4 - s^2}\sqrt{4 - t^2}$ is the Radon-Nikodym derivative of $\mu$ with respect to $\lambda \otimes \lambda$.

Consider now an arbitrary element $\zeta$ in $\text{Pol}(O_\infty) \cap A^\perp$. It can be written as a finite linear combination of coefficients corresponding to orthogonal vectors as above, hence the probability measure $\mu_\zeta$ defined by

$$\langle a\zeta b, \zeta \rangle = \int_{-2}^{2} \int_{-2}^{2} a(s)b(t)d\mu_\zeta(s,t).$$
has a density of the form $f(s, t)\sqrt{4 - s^2}\sqrt{4 - t^2}$ with respect to $\lambda \otimes \lambda$, where $f$ is analytic on $[-2, 2] \times [-2, 2]$. Since $\mu_\xi$ is obviously non-zero, $f$ does not vanish identically and by analyticity its zeros are contained in a set of Lebesgue measure 0, so that $\mu_\xi$ is equivalent to $\lambda \otimes \lambda$. Because $\text{Pol}(O_2^+) \cap A^+$ is dense in $L^2(M) \oplus L^2(A)$, this implies that $[\nu] = [\lambda \otimes \lambda]$. □

Note that as a consequence, the $A - A$-bimodule $L^2(M) \oplus L^2(A)$ is contained in a multiple of the coarse bimodule, see [13, Section 2]. Since the coarse bimodule is mixing, we can also recover Theorem 5.7 in this way.

5.4. Concluding remarks. We would like to briefly discuss some possible extensions of this work. First consider the quantum automorphism group $G(M_N(\mathbb{C}), \text{tr})$ of $M_N(\mathbb{C})$ endowed with the canonical trace. It is known that the von Neumann algebra $L^\infty(G(M_N(\mathbb{C}), \text{tr}))$ of this quantum group embeds into $L^\infty(O_N^+)$ as the subalgebra generated by all $u_{\xi, \eta}^{2n}$ for $n \in \mathbb{N}$ and $\xi, \eta \in H_{2n}$. Let us set $v^n = u^{2n}$. Then, the $v^n$’s form a complete family of representatives of irreducible representations of $G(M_N(\mathbb{C}), \text{tr})$ with corresponding characters $\psi_n = \chi_{2n}$. In particular, for any orthogonal unit vectors $\xi, \eta \in H_{2n}$ and $\xi', \eta' \in H_{2k}$,

$$\langle \psi_n^{\xi, \eta}, v^n \psi_n^{\xi', \eta'} \rangle \leq K q^{\max(2l, 2l')}$$

by Theorem 4.3. From this we see that the radial subalgebra in $L^\infty(G(M_N(\mathbb{C}), \text{tr}))$ is maximal abelian and mixing and that its associated bimodule is a direct sum of coarse bimodules. This is an interesting example because $G(M_N(\mathbb{C}), \text{tr})$ has $SO(3)$-type fusion rules, like another important family of discrete quantum groups called the quantum permutation groups $S_N^q$. This of course suggests that our result extends to $S_N^q$. One way to prove this may be through monoidal equivalence [3].

Another possible extension of our work would be to the non-Kac case. It is possible that the estimate of Theorem 4.3 still holds with appropriate modification for an arbitrary free orthogonal quantum group. However, the proofs of Section 5 all break down if the von Neumann algebra is type III, because the radial MASA has no $h$-invariant conditional expectation in that case. There is therefore an additional von Neumann algebraic problem to solve in that case, but this could yield very explicit examples of singular MASAs in type III factors.
