Abstract
We study a class of elliptic SPDEs with additive Gaussian noise on \( \mathbb{R}^2 \times M \), with \( M \) a d-dimensional manifold equipped with a positive Radon measure, and a real-valued non-linearity given by the derivative of a smooth potential \( V \), convex at infinity and growing at most exponentially. For quite general coefficients and a suitable regularity of the noise we obtain, via the dimensional reduction principle discussed in [11], the identity between the law of the solution to the SPDE evaluated at the origin with a Gibbs type measure on the abstract Wiener space \( L^2(M) \). The results are then applied to the elliptic stochastic quantization equation for the scalar field with polynomial interaction over \( \mathbb{T}^2 \), and with exponential interaction over \( \mathbb{R}^2 \) (known also as Hoegh-Krohn or Liouville model in the literature). In particular for the exponential interaction case, the existence and uniqueness properties of solutions to the elliptic equation over \( \mathbb{R}^{2+2} \) is derived as well as the dimensional reduction for all values of the “charge parameter” \( \sigma = \alpha^2 / \sqrt{\pi} < \sqrt{8\pi} \) for which the model has an Euclidean invariant measure (hence also permitting to get the corresponding relativistic invariant model on the two dimensional Minkowski space).

A Besov spaces 34
1 Introduction

The Euclidean approach to quantization of relativistic non-linear wave equations requires the construction of certain probability measure supported on distributions satisfying a set of quite strong requirements among which invariance under the full group of rigid motions of the Euclidean space and reflection positivity. Such constructions have succeeded in the case where the dimension \(d\) of the Euclidean space is equal to 1, 2, 3 (that is also the dimension of the space-time of the original relativistic equation). The non-linearity is quite general if \(d = 1\), whereas it is restricted to the derivatives of polynomials of even degree respectively suitable superpositions of trigonometric or exponential functions for \(d = 2\), or a cubic monomial function for \(d = 3\) (the \(\varphi^4_3\) model). In these cases a number of interesting physical and mathematical properties of the quantised relativistic fields models have been put in evidence.

In recent years new methods coming from the study of singular partial stochastic differential equations (SSPDEs) have been developed and have opened the possibility of new constructions of such Euclidean measures (and other similar measures associated with problems coming from other areas of applications, like statistical mechanics, hydrodynamics, wave propagation in random media ...). In these approaches the relevant Euclidean invariant measures are obtained as invariant measures for certain parabolic semilinear SPDEs called stochastic quantization equations (SQEs).

Typically the measures to be constructed have the heuristic form

\[
\mu(d\varphi) = Z^{-1} e^{-S(\varphi)} D\varphi,
\]

where \(\varphi = \varphi(x) \in \mathbb{R}, x \in \mathbb{R}^d\), \(D\varphi = \Pi_{\varphi \in \mathbb{R}} d\varphi(x)\) is a “flat measure”, \(Z\) is a “normalisation constant”, \(S(\varphi) = S_0(\varphi) + \lambda S_{\text{int}}(\varphi)\) with \(S_0(\varphi) = \frac{1}{2} \int_{\mathbb{R}^d} | \nabla \varphi(x)|^2 dx + m^2 \int_{\mathbb{R}^d} \varphi(x)^2 dx\), and where \(\lambda \geq 0, m \geq 0\) are parameters,

\[
S_{\text{int}}(\varphi) = \int_{\mathbb{R}^d} V(\varphi(x)) dx,
\]

for some (non-linear) measurable real valued function \(V\) over \(\mathbb{R}\). Note that \(\mu(d\varphi)\) is heuristically invariant under Euclidean transformations (translations and rotations and also additional reflections, in the case where \(V\) is an even function).

The associated stochastic quantization equation (first introduced in [62]) is of the form

\[
dX_{\tau} = (\Delta - m^2)X_{\tau} dt - V'(X_{\tau}) dt + dW_{\tau}
\]

where \(\tau\) is an additional “computer time”, \(\Delta\) is the Laplacian in \(\mathbb{R}^d\), \(X_{\tau} = X_{\tau}(x), x \in \mathbb{R}^d\), is a random variable taking values, for fixed \(\tau\), in the space of “(generalised) functions” of \(x\), \(dW_{\tau}(x)\) is a Gaussian white noise in \(\tau\) and \(x\), and \(V'\) in the derivative of \(V\).

Following a terminology used especially when \(V\) is a polynomial \(P\), we call the above SPDE the \(V(\varphi)\)-stochastic quantization equation (SQE). Various detailed results have been obtained on \(P(\varphi)\) SQEs, see the introduction of [7] and [15, 16] for references. In particular in [34] were obtained a strong solution and a unique ergodic measure in the case where \(R\) is replaced by the 2-torus \(\mathbb{T}^2\).

As for the case of the \(\varphi^4_3\) SQE, a breakthrough for local in time solutions of the SQE on the 3-torus \(\mathbb{T}^3\) came from [15] see also [32, 47]. More recently still for the case of the 3-torus \(\mathbb{T}^3\) a construction of invariant solutions has been given in [7]. This can be looked upon as a construction of the \(\varphi^4_3\)-measure on \(\mathbb{T}^3\), by methods different from the previous ones provided by mathematical physics approaches, see references in [13]. The methods in [7] have been simplified and extended to the case of \(\mathbb{R}^3\) in [15], yielding a full alternative construction of the measures which qualify to be called \(\varphi^4_3\) Euclidean measures. A previous approach following [15] is in [60]. A number of open problems has been mentioned in [7, 15], the main one concerns the uniqueness of the invariant measures.

Other approaches are however possible if one understands stochastic quantization in the broader sense of associating to a given heuristic “Euclidean measure” a stochastic process having this very measure as suitable marginal. A first approach consists in constructing a jump type process via infinite dimensional quasi-regular jump-type Dirichlet forms [5, 9, 23, 24] (for such Dirichlet forms see also [8]), that has by construction the given Euclidean measure as invariant measure.
Another approach obtains the invariant measure of a SQE in dimension $d$ by looking at solutions of a suitable associated elliptic SPDE in dimension $d + 2$ and restricting the solution to the $d$ dimensional Euclidean space obtained sending to zero the two additional variables. This latter procedure is known in the physical literature as Parisi-Sourlas dimensional reduction and has been implemented by using algebraic methods of supersymmetry (see [61]). For the case of a regularised non-linear term in the original SQE and regularised noise it has been studied from a mathematical point of view in [55].

Elliptic stochastic PDEs related to stochastic quantization of the $\varphi^4_2$ and $\varphi^4_3$ models respectively have been discussed both on the torus and in all space in [40]. A systematic mathematical investigation of the mechanism of dimensional reduction has been initiated in [11], for the $V(\varphi)_0$ model, for both the cases where $V$ is a convex function and also the case where $V$ is non-convex, where an interesting phenomenon of non-uniqueness of solutions has been put in evidence.

In fact in [11] an explicit formula for the law of the solution of a class of elliptic SPDE in $\mathbb{R}^2$ taken at the origin has been obtained, by means of a rigorous version of dimensional reduction. Besides proving an instance of elliptic stochastic quantization for the case of Euclidean dimension $d = 0$, it also provided a realisation of the relation between a supersymmetric quantum field model and an elliptic SPDE.

The present paper has two principal aims. The first one is to prove the dimensional reduction principle for elliptic SPDEs with non-singular noise for equations in $d + 2$ dimensions with $d > 0$. The second is to extend the result to elliptic singular SPDE having applications in stochastic quantization program and analysing the corresponding the dimensional reduction wrt. to removal of spatial cut-offs.

We restrict our attention to singular SPDEs with $d = 2$ and analyse polynomial and exponential interactions. In particular, in the case of potentials of the form $\exp(\sigma \varphi)_2$, for suitable real $\sigma$ we are able to complete the dimensional reduction picture removing all the spatial cutoff (i.e. in both the “fictitious” and “real” spatial variables).

Before passing to a more detailed description of our results, let us stress the importance of the $\exp(\sigma \varphi)_2$ model (and related ones) in relativistic and Euclidean quantum field theory. The $\exp(\sigma \varphi)_2$ model over $\mathbb{R}^2$ has been first introduced by Høegh-Krohn [52] (see also [14] and [67], p. 178 and 307-313) and constructed for an interaction of the form

$$U_g(\varphi) := \int :e^{\sigma \varphi(z)} : g(z)dzd\nu(\sigma)$$

for any positive space cut-off function $g \in L^1(\mathbb{R}^2) \cap L^2(\mathbb{R}^2)$ and any positive finite measure $\nu$ with support in $(-\sqrt{4\pi}, \sqrt{4\pi})$, in the sense that the interacting measure

$$\mu_g(\text{d}\varphi) := \frac{e^{-U_g(\varphi)} \mu_0(\text{d}\varphi)}{\int e^{-U(\varphi)} \mu_0(\text{d}\varphi)},$$

for $m > 0$, is absolutely continuous with respect to Nelson’s free field Gaussian measure $\mu_0$ with mean zero and covariance $(m^2 - \Delta_2)^{-1}$, $z \in \mathbb{R}^2$, (realised as a probability measure on, for example, $S'((\mathbb{R}^2))$). See [14] [52] and [67] p. 178 for further properties of the measure $\mu_g$. This model has been discussed in the infinite volume limit $g \to 1$, that is unique, in a further paper [14], under the more restrictive assumption that $\text{supp}(\nu) \subset \left[-\frac{4}{\sqrt{\pi}}, \frac{4}{\sqrt{\pi}}\right]$.

In fact in [14] the authors prove that the measure of the $\exp(\sigma \varphi)_2$ model for $|\sigma| < \sqrt{4\pi}$ (or more generally of suitable superpositions $\int \text{Ch}(\sigma \varphi)_2 \text{d}\varphi$ of these models) satisfies all axioms of Euclidean quantum field theory and leads to relativistic quantum fields over two-dimensional Minkowski space-time satisfying all Wightman axioms with interaction and a positive, finite mass gap at the lower end of the spectrum of the corresponding Hamiltonian.

Further properties of such models were discussed in, e.g., [3, 4, 39, 42, 51, 67], and [9, 15, 17, 22, 57]. The case $|\sigma| < \sqrt{8\pi}$ was discussed by S. Kusuoka in [50] and the relation with independent
work on multiplicative chaos by J. P. Kahane [54] (see also below) was pointed out by H. Sato. In [16] and also [67] estimates in $L^p$ (for the interaction in a bounded region) were given for $|\sigma| < \sqrt{\frac{4\pi}{d-3}}$. The Gaussian character of the model for $|\sigma|$ sufficiently large or for any $\sigma$ if the Euclidean space dimension $d$ satisfies $d \geq 3$ has been pointed out in [16] and [2].

The relevance of the $\exp(\sigma \varphi)$ model for Polyakov string theory has been discussed in [18, 19, 20] ($|\sigma| < \sqrt{4\pi}$ corresponding to the embedding dimension $D < 13$) and rediscovered more recently in connection with topics like Liouville model quantum gravity and multiplicative chaos. Let us mention in this connection [25, 37, 63] see also [29, 36, 44, 66] (for the literature for other approaches to Liouville type models not directly connected with probabilistic methods see, e.g. [26]).

Finally a connection of the $\exp(\sigma \varphi)$ model with the irreducibility of a unitary representation of the group of mappings of a manifold into a compact Lie group has been pointed out and studied in [10], see also the recent work [11].

The $\exp(\sigma \varphi)$ model is also closely connected with the $\sin(\sigma \varphi)$ model (“Sine-Gordon equation”) as discussed in [13, 40]. In the latter reference all Wightman axioms are proved again in the region $|\sigma| < \sqrt{4\pi}$.

Both in the $\exp(\sigma \varphi)$ model and the $\sin(\sigma \varphi)$ model a replacement of the $\exp$ (respectively sin) function by a Wick ordered version is needed (see [12]) but also suffices for the existence and non-triviality of the model for $|\sigma|$ up to $\sqrt{4\pi}$. For larger values of $|\sigma|$, in the case of the $\sin(\sigma \varphi)$ model, up to $\sqrt{8\pi}$, further renormalisation by counter-terms is required (see [28]).

The study of the stochastic quantization equation associated with the latter class of models has been initiated in [12] (where strong solutions have been discussed and the necessity of renormalisation has been pointed out). In the case where $\mathbb{R}^2$ (or $\mathbb{T}^2$) is replaced by $\mathbb{R}$ (respectively $\mathbb{T}$), i.e. for the model $\exp(\sigma \varphi)$, a deeper analysis is possible and has been pursued in [21], where the existence of solution and the strong uniqueness of the invariant measure are proven (for the corresponding stochastic quantization of $P(\varphi)_1$ see [53]).

The case of the SQE in $d = 2$ and with a regularised noise on the torus (and corresponding changes in the coefficients of the stochastic quantization equation needed to keep the same invariant measure) has been discussed in [58] (see also [6] for further development), where existence of solutions was proven using essentially the properties of the $\exp(\sigma \varphi)$ model established in [14] and methods of [54]. Uniqueness problems are also discussed in [6] in conjunction with an approach using Dirichlet forms.

Hairer and Shen [59] introduced powerful methods to handle the dynamical $\sin(\sigma \varphi)$ model on $\mathbb{T}^2$, and via regularity structures local existence is shown up to $\sigma^2 < \frac{16}{\pi} \pi$. More recently these results has been extended in [63] to cover all the subcritical regime $\sigma^2 < 8\pi$.

Concerning the exponential interaction, the work of Garban [41] appeared recently in which the author studies the SQE on the torus $\mathbb{T}^2$ and on the sphere $\mathbb{S}^2$. After subtracting the solution to the linear equation he obtains an SPDE driven by a multi-fractal and intermitted multiplicative chaos. When $|\sigma| < (4 - 2\sqrt{3}) \sqrt{\pi} (< \sqrt{4\pi})$ (a regime correspondingly called Da Prato-Debussche phase) he shows the existence of a strong solution and the convergence of the solution to the equation with regularised noise to the singular one both on the torus $\mathbb{T}^2$ and on the sphere $\mathbb{S}^2$ (see Theorem 1.7 and Theorem 1.9 in [41]). The method used is based on the Besov regularity of the Gaussian multiplicative chaos (related to the theory of [53]). The paper [41] also refers to other interesting relations to quantum gravity, conformal fields theory, strings theory, multiplicative chaos and exciting new results on random measures. A result on existence and uniqueness for the equation (without the proof of the convergence of the solution to the equation with regularised noise to the singular one) is also proved (Theorem 1.11 in [41]) for $|\sigma| < (4 - 2\sqrt{2}) \sqrt{\pi} (< \sqrt{4\pi})$. Moreover a comparison with the SQE for the Sine-Gordon model is provided (cfr. Section 7 in [41]).

Let us briefly review and comment the main results obtained in this paper. In Section 2 we study the case of the following elliptic SPDE (equation (11) in Section 2)

$$(-\Delta_x + m^2 + \mathcal{L})(\phi)(x, z) + \mathcal{A}^2 f(x') g(z') V'(\phi(x', z'))(x, z) = \xi^4(x, z)$$

4
on $\mathbb{R}^2 \times M$, with $M$ a $d$-dimensional manifold with or without boundary, equipped with a positive Radon measure $dz$ and a real-valued non-linearity given by the derivative of a positive smooth function $V$ defined on the real line growing at most exponentially at infinity. We use the shorthand $f(x')g(z')V'(\phi(x', z'))$ with free variables $(x', z')$ to mean the function $(x', z') \mapsto f(x')g(z')V'(\phi(x', z'))$. Additional assumptions are as follows. The function $V$ is taken to the convex or “quasi convex” (see Hypothesis QC below). $\mathfrak{L}$ and $\mathcal{A}$ are two positive self-adjoint operators acting on $L^2(M)$, $\mathfrak{L}$ is bounded, $\mathcal{A}$ is not-necessarily bounded but has a dense domain in $L^2(M)$, $\mathfrak{L}$ and $\mathfrak{A}$ commute and both have completely discrete spectrum with some additional hypotheses on the eigenfunctions and the eigenvalues of $\mathcal{A}$. The noise $\xi$ is supposed to be Gaussian with mean zero and covariance corresponding to a regularisation given by $\mathfrak{A}$. Finally $f$ is a $C^2$ real-valued cut-off function on $\mathbb{R}^2$, decaying exponentially at infinity and $g$ is a smooth real-valued cut-off with compact support on $M$.

We introduce finite dimensional projections relative of $\mathfrak{A}$ and prove the existence of a weak solution $\nu$ satisfying a form of the dimensional reduction principle described in our previous paper [11], extended to the $d$ dimension case with the presence of a non-trivial operator $\mathfrak{L}$. See Theorem 2 for a precise statement.

Next we prove extensions of these results in two directions: in Section 2.2 we consider the case $M = \mathbb{R}^d$, $\mathfrak{L} = -\Delta_2$ (cfr. Theorem 3), in Section 2.3 we consider the problem of the removal of the cutoffs $f, g$ in the case where $V$ is a convex function (cfr. Theorem 4).

The first part of the present paper contains the first example of rigorous dimensional reduction for elliptic SPDE in $d + 2$ dimension with $d > 0$. Indeed, the other only paper which to our knowledge study dimensional reduction from the rigorous point of view is [55] whose main result is a theorem about the dimensional reduction of an integral in a space of functions in $d + 2$ variables to a Gibbs type measure in a space of functions in $d$ variables. In particular the authors do not attack the problem of the relation with the elliptic SPDE. Furthermore in [55] only polynomial potentials $V$ are considered and the regularisation of the noise is chosen to be compactly supported in Fourier space. Ours Hypothesis QC on the potential $V$ and Hypotheses HA, HAI for the regularisation of the noise considered here are quite more general. Let us stress that the results obtained under these more general hypotheses uses in essential way the SPDE formulation of dimensional reduction.

In Section 3 we extend our result to singular SPDEs. In particular the elliptic stochastic quantization of the exponential interaction is proven, where $V$ is a suitable renormalised exponential function $\exp(\alpha \phi - \infty)$, for $|\alpha| < 4\sqrt{2}\pi$ (corresponding to the reduced index $|\sigma| < \sqrt{2\pi}$), and the white noise is unregularized. Existence and uniqueness is first proven for suitable regularised model using the results of the previous sections (cfr. Theorem 5). Subsequently the removal of the regularisation in the noise is achieved in the Besov space $B^{s}_{p,p}(\mathbb{R}^d)$, where $-1 < s < 0$ and $1 < p \leq 2$ are suitable constants depending only on $\alpha$. Using the existence, uniqueness and convergence results for the elliptic SPDEs over $\mathbb{R}^d$ proven in Section 2.3 the existence and uniqueness results for the elliptic stochastic quantization equation for exponential interaction follows in Theorem 7. The dimensional reduction result is then obtained (cfr. Theorem 5) with uniqueness for all $|\alpha| < 4\sqrt{2}\pi$. Our last result in this section, Theorem 9 shows the convergence and uniqueness of the equation when the spatial cut-off $g$ is removed. As an easy corollary one obtains the full Euclidean invariance of the law of the solutions.

Finally in Section 4 we prove the existence for singular elliptic SPDE with Wick power non linearity in $d + 2 = 4$ dimension. Furthermore we prove a dimensional reduction principle for some weak solutions to SPDEs of this form providing the first example of elliptic stochastic quantization for the polynomial interaction model $P(\varphi)_2$. Let us stress that for polynomial interactions the problem of uniqueness of weak solutions to the elliptic SPDE is open and this prevents a more detailed analysis of the dimensional reduction.

The results contained in this second part of the paper gives the first example of dimensional reduction for singular elliptic SPDE as originally formulated by Parisi and Sourlas in [61]. In particular with respect to [60], where the existence for singular elliptic SPDEs with polynomial
type non-linearity is proven for both $d + 2 = 4$ and, with cubic type non-linearity, $d + 2 = 5$ dimension, in Section 3 we prove, at least in the $d + 2 = 4$ dimensional case, they can be used as stochastic quantization equation for quantum field theory. However many problems still remains open wrt. the removal of the spatial cutoffs.

Let us stress that, in Section 3, we prove existence and uniqueness of solutions for elliptic SPDE and the relation with the Liouville measure in the full subcritical regime $|\sigma| < \sqrt{8\pi}$. This result is achieved using in an essential way two properties of the exponential model: the fact that the Wick exponential of a distribution is a positive measure (this fact is already exploited in [41]), and the multifractality of Wick exponentials (see Lemma 8 for a precise formulation of this property).

In particular we prove the existence and uniqueness for the elliptic SPDE with Wick exponential non-linearity using the space $B^{-s}_{p,p,\ell}(\mathbb{R}^4)$, instead of $B^{-s}_{\infty,\infty,\ell}(\mathbb{R}^4)$, and only the Da Prato-Debussche trick. This is possible since for any exponent $|\sigma| < \sqrt{8\pi}$ the noise lives in inside $B^{-s}_{p,p,\ell}(\mathbb{R}^4)$ for some $s < 1$ and $1 < p \leq 2$, instead for $|\sigma| \geq (4 - 2\sqrt{2})\sqrt{\pi} (< \sqrt{4\pi})$ the Wick power of the noise is in $B^{-s}_{\infty,\infty,\ell}(\mathbb{R}^4)$ with $s > 2$. The other novelty is the fact that we are able to solve the equation in the full space and we are easily able to prove the Euclidean invariance of the law.

The other best result, to our knowledge, concerning stochastic quantization of exponential interaction, is the paper [41], which studied the stochastic quantization in the parabolic setting for the charge parameter $|\sigma| < (4 - 2\sqrt{2})\sqrt{\pi} (< \sqrt{4\pi})$. We think that the analytic methods, developed here in Section 3.2, joined with the probabilistic results, typical of the parabolic setting obtained in [41], can also be applied to the parabolic case for the whole subcritical regime $|\sigma| < \sqrt{8\pi}$.

2 Dimensional reduction with regularised noise

2.1 Discrete spectrum

Consider the following elliptic SPDE

$$(-\Delta x + m^2 + \xi)(\phi)(x, z) + \mathcal{A}^2[f(x')g(z')\partial V(\phi(x', z'))](x, z) = \xi^A(x, z)$$

(1)

where $x \in \mathbb{R}^2$ and $z \in M$ (where $M$ is a $d$ dimensional manifold with or without boundary, equipped with a Radon positive measure $dz$) and $V$ is a smooth function on $\mathbb{R}$ growing at most exponentially at infinity, $\partial V$ its gradient and $\phi : \mathbb{R}^2 \times M \to \mathbb{R}$ a scalar random field.

We now list the hypotheses and assumptions on the various elements of equation (1) and of its generalisation to the vector case, where $V$ is replaced by $V_n$ being defined on $\mathbb{R}^n$ (when $\mathbb{R}^n = \mathbb{R}$ hereafter instead of writing $V_1$ we simply write $V$).

Hypothesis C. The potential $V_n : \mathbb{R}^n \to \mathbb{R}$ is a positive smooth function such that

$$y \in \mathbb{R}^n \mapsto V_n(y),$$

is strictly convex and it and its first and second partial derivatives grow at most exponentially at infinity.

Hypothesis QC. The potential $V_n : \mathbb{R}^n \to \mathbb{R}$ is a positive smooth function, such that it and its first and second partial derivatives grow at most exponentially at infinity and additionally such that there exists a function $\mathcal{S} : \mathbb{R} \to \mathbb{R}$ with exponential growth at infinity such that we have

$$-\langle \hat{n}, \partial V_n(y + r\hat{n}) \rangle \leq \mathcal{S}(y), \quad \hat{n} \in \mathbb{S}^{n-1}, y \in \mathbb{R}^n \text{ and } r \in \mathbb{R}_+,$$

with $\mathbb{S}^{n-1}$ is the $n - 1$ dimensional sphere.
**Hypothesis Hf.** The function \( f : \mathbb{R}^2 \to \mathbb{R} \) has at least \( C^2 \) smoothness and in addition satisfies \( f'' \leq 0 \), it decays exponentially at infinity and fulfills \( \Delta(f) \leq b^2 f \) for \( b^2 \ll m^2 \) (some examples of such functions are given in [53]).

**Hypothesis Hg.** The function \( g : M \to \mathbb{R} \) is smooth and with compact support.

**Hypothesis Hξ.** The operator \( \mathfrak{L} \) is a closed operator (possibly unbounded) defined on the vector space \( D_\mathfrak{L} \subset L^2(M) \) (where \( L^2(M) \) is the space of measurable \( L^2 \) functions defined on \( M \) with respect the measure \( dz \) on \( M \)), which is dense in \( L^2(M) \). The range of \( \mathfrak{L} \) is a subset of \( L^2(M) \). The operator \( \mathfrak{L} \) is positive and self-adjoint and has a completely discrete spectrum. Furthermore we suppose that there exists at least an orthonormal basis \( H_1, \ldots, H_k, \ldots \) in \( L^2(M) \) composed by eigenfunctions of \( \mathfrak{L} \) which are \( C^0(M) \) functions (where \( C^0(M) \) is the space of continuous functions \( h \) defined on \( M \) such that \( \| h(z)w(z) \|_\infty < +\infty \) where \( w \) is a given positive weight continuous function). Finally we denote by \( \lambda_1 \leq \lambda_2 \leq \cdots \leq \lambda_k \leq \cdots \) the eigenvalues of \( \mathfrak{L} \) corresponding to the eigenfunctions \( H_1, H_2, \ldots \).

**Hypothesis HA.** The operator \( A : L^2(M) \to L^2(M) \) is a linear, injective, continuous, positive self-adjoint operator commuting with \( \mathfrak{L} \). If we denote by \( \sigma_1, \ldots, \sigma_k, \ldots \) the eigenvalues of \( A \) corresponding to the basis \( H_1, \ldots, H_k, \ldots \) we suppose that

\[
\sum_{k=1}^\infty \sigma_k < +\infty \quad \sum_{k=1}^\infty \sigma_k \| H_k \|_{L^2(M)}^2 < +\infty,
\]

where \( \| \cdot \|_{L^2(M)} \) denotes the \( L^2 \)-norm on the weighted space \( C^0(M) \).

**Hypothesis Hξ.** The noise \( \xi^A \) is Gaussian with mean zero and a covariance corresponding to a regularisation provided by \( A \), namely such that if \( h_1, h_2 \in C^\infty(\mathbb{R}^2 \times M) \) we have

\[
\mathbb{E}[\langle h_1, \xi^A \rangle, \langle h_2, \xi^A \rangle] = \int_{\mathbb{R}^2 \times M} (I \otimes A)(h_1)(x, z)(I \otimes A)(h_2)(x, z)dx\,dz.
\]

**Remark 1** When \( V_1 = V : \mathbb{R} \to \mathbb{R} \), Hypothesis QC can be reformulated as

\[
\exists V'(y \pm r) \leq S(y),
\]

where \( r \geq 0 \).

In the rest of this Subsection we will always assume Hypothesis Hf, Hg, Hξ, HA and we specify the use of Hypothesis QC or C case by case. Moreover, hereafter we systematically use the following abuse of notation: we denote by \( \mathfrak{L} \) and \( A \) both the operators with the same name defined on the space \( L^2(M) \) and also the operators \( I \otimes \mathfrak{L} \) and \( I \otimes A \) defined on \( L^2(\mathbb{R}^2 \times M) \).

We describe now the setting for equation (3.1). We assume that \( \xi^A \) is defined on an abstract Wiener space \( (\mathcal{W}, \mathcal{H}, \mu^A) \) where the Cameron-Martin space is

\[
\mathcal{H} = L^2(\mathbb{R}^2) \otimes_H \mathcal{A}(L^2(M)),
\]

(here \( \otimes_H \) is the natural tensor product of Hilbert spaces) equipped with the following scalar product

\[
\langle h_1, h_2 \rangle = \int_{\mathbb{R}^2 \times M} A^{-1}(h_1)(x, z)A^{-1}(h_2)(x, z)dx\,dz, \quad h_1, h_2 \in \mathcal{H}.
\]

The Wiener space \( \mathcal{W} \) is given by

\[
\mathcal{W} = (-\Delta_x + 1)(C^0_\ell(\mathbb{R}^2) \cap W^{1-b}_\ell(\mathbb{R}^2)) \otimes x \mathcal{A}^{1/2}(L^2(M)),
\]

where \( \ell \geq 0 \), \( C^0_\ell(\mathbb{R}^2) \) is the space of continuous functions on \( \mathbb{R}^2 \) such that

\[
\| k \|_{\infty, \ell} = \sup_{x \in \mathbb{R}^2} (| k(x) | (1 + | x |)^{-\ell}),
\]
$W^{1-p}_\ell(\mathbb{R}^2)$ denotes the Sobolev space of regularity 1− and weight $r_\ell = (1 + |x|)^{-\ell}$, $\otimes_\pi$ denotes the projective tensor product (see [65]). The measure $\mu^A$ is the centred Gaussian measure with Cameron-Martin space $\mathcal{H}$.

In order to prove that $(\mathcal{W}, \mathcal{H}, \mu^A)$ is actually an abstract Wiener space it is sufficient to prove that $\mathbb{E}[\|\xi^A\|_W] < +\infty$ where $\| \cdot \|_W$ denotes the norm of $\mathcal{W}$. We have that

$$\xi^A(x, z) = \sum_{k=1}^{\infty} \sigma_k \xi^k(x) H_k(z), \quad (2)$$

where $x \in \mathbb{R}^2$, $z \in M$, $\xi^k$ are a sequence of independent Gaussian white noises defined on $\mathbb{R}^2$ and $\sigma_k$ are defined as in Hypothesis HA. We have that

$$\|\xi^A\|_W \lesssim \left( \sum_{k=1}^{\infty} \sigma_k \| H_k \|_{L^2(M)}^2 \right)^{1/2} \lesssim \sum_{k=1}^{\infty} \sigma_k < +\infty,$$

(1)

On the other hand, by Hypothesis HA, we obtain

$$\mathbb{E} \left[ \sum_{k=1}^{\infty} \sigma_k \| (-\Delta + 1)^{-1}(\xi^k) \|_{C^0_\mathcal{L}(\mathbb{R}^2) \cap W^{1-p}_\ell(\mathbb{R}^2)}^2 \right] \lesssim \sum_{k=1}^{\infty} \sigma_k < +\infty,$$

where $\lesssim$ stands for $\leq$ modulo a multiplicative positive constant and $\sum_{k=1}^{\infty} \sigma_k \| H_k \|_{L^2(M)} = \sum_{k=1}^{\infty} \sigma_k < +\infty$, and thus $\mathbb{E}[\|\xi^A\|_W] < +\infty$. This proves that $(\mathcal{W}, \mathcal{H}, \mu^A)$ is an abstract Wiener space when $\xi^A : \mathcal{W} \to \mathcal{W}$, defined as $\xi^A(w) = w$, has exactly $\mu^A$ as probability distribution.

For later use, it is important to note that $\mathcal{W}$ is continuously embedded in $\mathcal{W}' = (-\Delta + 1)(C^0_\ell(\mathbb{R}^2) \cap W^{1-p}_\ell(\mathbb{R}^2)) \otimes_\pi C^0_\mathcal{L}(M)$, since $A^{1/2}(L^2(M))$ is continuously embedded in $C^0_\mathcal{L}(M)$ by Hypothesis HA.

Equation (4) can be written as a problem defined on the abstract Wiener space $(\mathcal{W}, \mathcal{H}, \mu^A)$. In particular we define the map $U : \mathcal{W} \to \mathcal{H}$ by

$$U(w) = A^2[f(x)g(z)V'(Iw)],$$

where $I : \mathcal{W} \to (-\Delta + 1)^{-1}(\mathcal{W})$ is the linear operator given by $I = (-\Delta + m^2 + \mathcal{L})^{-1}$. We define the map $T : \mathcal{W} \to \mathcal{W}$ as $T(w) = w + U(w)$.

Definition 1 It is clear that if $S$ is any measurable map $S : \mathcal{W} \to \mathcal{W}$ satisfying $T \circ S = \text{id}_\mathcal{W}$ and $\mu^A$-almost surely we have that $\phi(w, x, z) = I(S(w))(x, z)$ is a (strong) solution to equation (4).

Furthermore: if $\nu$ is a probability law on $\mathcal{W}$ such that $T_\nu(\nu) = \mu^A$ then a random variable $\phi$ taking values on $\mathcal{W}$ and having the same law as $I_\nu(\nu)$ is a (weak) solution to equation (4). For this reason in the following we call a map $S : \mathcal{W} \to \mathcal{W}$ such that $T \circ S = \text{id}_\mathcal{W}$ $\mu^A$-almost surely a strong solution to equation (4) and we call a measure $\nu$ on $\mathcal{W}$ such that $T_\nu(\nu) = \mu^A$ weak solution to equation (4).

In order to solve equation (4) we need to introduce an approximation. Let $P_n$ be the orthogonal projection in $L^2(M)$ onto the finite dimensional subspace generated by $H_1, \ldots, H_n$. The restrictions $P_n|_{A^{1/2}(L^2(M))}$ and $P_n|_{A^{1/2}(L^2(M))}$ of $P_n$ on $A^{1/2}(L^2(M))$ are the orthogonal projection on the subspace generated by $H_1, \ldots, H_n$ too. This implies also that $I \otimes P_n$ (in the following denoted also simply by $P_n$) is a continuous linear operator on $\mathcal{W}$.

Let $\phi_n$ be the solution to the following approximated equation

$$(-\Delta + \mathcal{L} + m^2)(\phi_n)(x, z) + P_n A^2[f(x')g(z')V'(P_n(\phi_n))(x', z')](x, z) = \xi^A(x, z), \quad (3)$$

and let $U_n(w) = P_n(U(P_n(w)))$ and $T_n(w) = w + U_n(w)$ be the maps, analogous to $U$ and $T$, related to equation (4). Using these objects we can define weak and strong solutions to equation (4) as in Definition 1.
Let us now study equation (4). We introduce the following function $V_n : \mathbb{R}^n \to \mathbb{R}$

$$V_n(y) = \int_M g(z) V \left( \sum_{k=1}^n y^k H_k(z) \right) \, dz.$$ 

Then, since $P_n$ commutes with $\mathcal{L}$ and $\mathcal{A}$, being the projection on a subset of common eigenfunctions of both $\mathcal{L}$ and $\mathcal{A}$, we have that $\phi_n$ is of the form

$$\phi_n(x, z) = I \xi^A(x, z) + \tilde{\phi}_n(x, z) = I \xi^A(x, z) + \sum_{k=1}^n \tilde{\psi}_n^k(x) H_k(z),$$

where $\tilde{\psi}_n^k(x)$ solves the set of equations

$$0 = (-\Delta_x + m^2 + \lambda_k)(\tilde{\psi}_n^k)(x) + \sigma_k^2 \int_M g(z) V' \left( \sum_{j=1}^n \mu_j \mathcal{I}_{\lambda_j} \xi^j(x) H_j(z) + \sum_{j=1}^n \tilde{\psi}_n^j(x) H_j(z) \right) H_n(z) \, dz \quad (4)$$

with $\mathcal{I}_{\lambda_j} = (-\Delta_x + \lambda_j + m^2)^{-1}$, $\tilde{\xi}(x) = (\sigma_j \mathcal{I}_{\lambda_j} \xi^j)(k=1, \ldots, n) \in \mathbb{R}^n$ and we used the fact that $\mathcal{A}$ is self-adjoint in $L^2(M)$. If we denote by $\mathcal{A}_n$ the $n \times n$ diagonal matrix such that $\mathcal{A}_n = \sigma_j \delta^{ij}$, $i, j = 1, \ldots, n$, and by $\mathcal{L}_n$ the $n \times n$ matrix such that $\mathcal{L}_n = \lambda_i \delta^{ij}$ we can write equation (4) in the following way

$$(-\Delta_x + m^2 + \mathcal{L}_n)(\psi_n) + \mathcal{A}_n \cdot \partial V_n(\psi_n) = \mathcal{A}_n \cdot \xi_n,$$ 

(5) 

where $\psi_n = (\tilde{\psi}_n^k + \tilde{\xi}_n^k)|_{k=1, \ldots, n}$. Equation (5) is defined on the abstract Wiener space $\tilde{\mathcal{H}}_n := L^2(\mathbb{R}^2, \mathbb{R}^n)$, with its natural scalar product and natural norm given by $\langle h, g \rangle = \sum_{i=1}^n \frac{1}{\sigma_i} \int_{\mathbb{R}^2} h^i(x) g^i(x) \, dx$. Let $\tilde{\mathcal{W}}_n$ (in which $\tilde{\mathcal{H}}_n$ is densely embedded) be the space $\tilde{\mathcal{W}}_n := W^{p-1}_\ell(\mathbb{R}^2; \mathbb{R}^n) \cap (1 - \Delta_x)(C^0(\mathbb{R}^2; \mathbb{R}^n))$ and $\tilde{\mu}_n$ is the law of the white noise $\tilde{\xi}_n = (\sigma_1 \xi^1, \ldots, \sigma_n \xi^n)$. On $\tilde{\mathcal{W}}_n$ we can define the corresponding maps $\tilde{U}_n(w)(x) = f(x) \partial V_n^A(\mathcal{I}_{\mathcal{L}_n}(w))$ and $\tilde{T}_n(w) = w + \tilde{U}_n(w)$ where

$$V_n^A(y) := V_n(\sigma_1 y^1, \ldots, \sigma_n y^n),$$

$y = (y^1, \ldots, y^n)$, $y^i \in \mathbb{R}$, $i = 1, \ldots, n$ and $\mathcal{I}_{\mathcal{L}_n}$ is the matrix valued operator defined as $\mathcal{I}_{\mathcal{L}_n} = \delta^{ij} \mathcal{I}_{\lambda_j}$. Using $\tilde{T}_n$ we can define the concept of strong and weak solutions to equation (5).

**Remark 2** It is important to note that the relationship between $\psi_n$ and the strong solution $\tilde{S}_n$ (defined using the map $\tilde{T}_n$) is given by $\psi_n(w, x) = \mathcal{I}_{\mathcal{L}_n}(\tilde{S}_n(w))(x)$, $x \in \mathbb{R}$. Furthermore if $\tilde{\nu}_n$ is a weak solution to equation (5) (i.e. such that $\tilde{T}_{n, \nu}(\tilde{\nu}_n) = \tilde{\mu}_n$) we have that $\tilde{\nu}_n$ is the law of $(-\Delta_x + m^2 + \mathcal{L}_n)(\psi_n)$.

In the following we shall denote by $\tilde{\kappa}^n$ the probability law on $\mathbb{R}^n$ such that

$$\frac{d\tilde{\kappa}^n}{dy} = \text{exp}(-2\pi((m^2 + \mathcal{L}_n)^{1/2}(\mathcal{A}^{-1}_n \cdot y)^2 + V_n(y)))$$

where $Z_{\tilde{\kappa}^n}$ is a suitable constant and $dy$ is the Lebesgue measure on $\mathbb{R}^n$. Finally we define $\tilde{\mathcal{Y}}_{f,n}$ as the random variable defined on $\tilde{\mathcal{W}}_n$ such that

$$\tilde{\mathcal{Y}}_{f,n}(w) := \text{exp} \left( 4 \int_{\mathbb{R}^2} f'(x) V_n(\mathcal{I}_{\mathcal{L}_n}(w)(x)) \, dx \right) = \text{exp} \left( 4 \int_{\mathbb{R}^2} f'(x) V_n(\psi_n(w, x)) \, dx \right).$$

9
Theorem 1 \textit{If } \nabla V^A_n \textit{ satisfies Hypothesis QC then there exists at least a weak solution } \hat{\nu}^n \textit{ to equation (4) such that for any bounded measurable function } F : \mathbb{R}^k \to \mathbb{R} \textit{ we have}

\begin{equation}
\int_{\mathbb{W}^n} F(\mathcal{T}_{\Sigma_n} w(0)) \hat{\chi}_{f,n}(w) d\hat{\nu}_n(w) = Z_{f,n} \int_{\mathbb{R}^n} F(y) d\hat{\eta}^n
\end{equation}

where

\[ Z_{f,n} := \int_{\mathbb{W}^n} \hat{\chi}_{f,n}(w) d\hat{\nu}_n(w). \]

\textbf{Proof} \ The proof is given in [11] Theorem 1 for the case \( \Sigma_n = 0 \). The case with \( \Sigma_n \) a generic positive diagonal matrix is a trivial extension. \( \square \)

It is simple to prove that if the potential \( V \) satisfies Hypothesis QC the potential \( V^A_n \) satisfies Hypothesis QC too, indeed the following proposition holds.

\textbf{Proposition 1} \textit{If } V : \mathbb{R} \to \mathbb{R} \textit{ satisfies Hypothesis QC then } V^A_n \textit{ satisfies Hypothesis QC. Finally if } V \textit{ is strictly convex (i.e. it satisfies Hypothesis C) also } V^A_n \textit{ and } V \textit{ are convex.}

\textbf{Proof} \ First of all we note that

\[ \partial^{\psi} V^A_n(y) = \int_M g(z) V'(A \left( \sum_{j=1}^n y^j H_j(z) \right)) A(H_k)(z) dz. \]

This means that if \( n \in \mathbb{S}^n \) we have

\[-n \cdot \partial V^A_n(y + tn) = - \sum_{k=1}^n n_k \partial y_k(V^A_n)(y + tn) \]

\[ \leq \int_M g(z) \psi \left( A \sum_{j=1}^n y^j H_j(z) \right) dz \]

\[ \leq \mathcal{H} \left( \left| n \right| \sum_{k=1}^{+\infty} \sigma_k \left\| H_k \mathbb{I}_{g(z) \neq 0} \right\|_{\infty} \right) \]

where we use that \( g \) has compact support, the fact that \( V \) satisfies Hypothesis QC and the fact that \( \mathcal{H} \) is increasing. Since

\[ \sum_{k=1}^{+\infty} \sigma_k \left\| H_k \mathbb{I}_{g(z) \neq 0} \right\|_{\infty} < \left\| \frac{1}{w} \mathbb{I}_{g(z) \neq 0} \right\|_{\infty} \sum_{k=1}^{+\infty} \sigma_k \| H_k \|_{\infty, w} < +\infty \]

by Hypothesis H4, the thesis is proved. \( \square \)

Using the weak solution \( \hat{\nu}^n \) to equation (4), given by Theorem 1 we are able to construct a weak solution to equation (5) satisfying the dimensional reduction principle.

A weak solution \( \nu_n \) to equation (5) is of the form \( \nu_n = \hat{\nu}_n \otimes \mu^A_n \), where \( \hat{\nu}_n \) is the law of

\[ (-\Delta_x + m^2 + \Sigma) P_n(\phi_n)(x, z) = \sum_{k=1}^n (-\Delta_x + m^2 + \lambda_k)(\psi^k_n)(x) H_k(z), \]

on the subspace \( \text{Im}(P_n) \subset \mathcal{W} \) and \( \mu^A_n \) is the law of

\[ Q_n(\phi_n) = (-\Delta_x + m^2 + \Sigma)(I - P_n)(\phi_n)(x, z) = \sum_{k=n+1}^{+\infty} \mu_k \xi^k(x) H_k(z), \]
which is the law of the Gaussian field on \(\text{Im}(Q_n) \subset W\). Using the basis \(H_1, \ldots, H_n\) we can identify the law \(\nu_n\) on \(\text{Im}(P_n)\) with a probability measure \(\hat{\nu}_n\) on \(\hat{W}^n\). In this way it is evident that if the law \(\hat{\nu}_n\) satisfies the dimensional reduction principle on \(\hat{W}^n\) then the probability law \(\nu_n = \hat{\nu}_n \otimes \mu^n\) satisfies the dimensional reduction principle on \(W\), since it is the tensor product of two probability laws satisfying the dimensional reduction principle.

More precisely, we consider the following abstract Wiener space \((W, H, \mu^{A,E})\) where

\[
W = \mathcal{A}^{1/2}(L^2(M)), \\
H = (\mathcal{L} + m^2)^{-1/2}(\mathcal{A}(L^2(M))),
\]

(with \(\mathcal{A}\) and \(\mathcal{L}\) as in \((\ref{H})\)) and \(W\) is equipped with its natural norm while on \(H\) we define the following scalar product

\[
\langle h_1, h_2 \rangle_H = \frac{1}{4\pi} \int_M (\mathcal{L} + m^2)^{1/2}(\mathcal{A}(h_1))(z)(\mathcal{L} + m^2)^{1/2}(\mathcal{A}(h_2))(z)dz. \tag{7}
\]

Thus \(\mu^{A,E}\) is the centred Gaussian measure on \(W\) with Cameron-Martin space given by \(H\). We now denote by \(\kappa_n\) the measure on \(W\) such that

\[
\frac{d\kappa_n}{d\mu^{A,E}}(\omega) = \exp \left(-4\pi \int_M g(z) V(P_n(\omega)(z))dz\right)/Z_{\kappa_n} \tag{8}
\]

where \(\omega \in W\) and \(Z_{\kappa_n}\) is a renormalisation constant.

We introduce also the following random variable

\[
\Upsilon_{f,n}(w) := \exp \left(4\int_{\mathbb{R}^2 \times M} f'(x)g(z) V(P_n(\omega w)(x,z))dx dz\right)
\]

where \(w \in W\). If we use the previous identification of \(\text{Im}(P_n)\) with \(\hat{W}^n\) we have that

\[
\hat{\Upsilon}_{f,n}(P_n(w)) = \Upsilon_{f,n}(w).
\]

Using the previous observations the next proposition trivially follows.

**Proposition 2** If \(V\) satisfies Hypothesis QC then there exists a weak solution \(\nu_n\) to equation \((3)\) such that for any measurable function \(F: W \to \mathbb{R}\) we have that

\[
\int_W F(\Upsilon_{f,n}(\cdot)) \Upsilon_{f,n}(w) d\nu_n(w) = Z_{f,n} \int_W F(\omega) d\kappa_n(\omega). \tag{9}
\]

The rest of the section concerns the generalisation of Proposition 2 to solutions to equation \((1)\). In particular we denote by \(\kappa\) the probability measure on \(W\) such that

\[
\frac{d\kappa}{d\mu^{A,E}}(\omega) = \exp \left(-4\pi \int_M g(z) V(\omega)(z)dz\right)/Z_{\kappa}, \tag{10}
\]

where \(\omega \in W\).

**Theorem 2** Suppose that \(V\) satisfies Hypothesis QC then there exists at least a weak solution \(\nu\) to equation \((1)\) such that for any Borel measurable function \(F: W \to \mathbb{R}\) we have

\[
\int_W F(\Upsilon_{f}(\cdot)) \Upsilon_{f}(w) d\nu(w) = Z_f \int_W F(\omega) d\kappa(\omega), \tag{11}
\]

where \(\kappa\) is defined as in \((8)\) and

\[
Z_f = \int_W \Upsilon_{f}(w) d\nu(w).\]
Remark 3 Since \( \kappa_n \) converges weakly to \( \kappa \), the right hand side of equation (11) converges to the right hand side of equation (11), as \( n \to +\infty \).

In order to prove Theorem 2 we prove the following lemmas. In the space of functions \( C_0^0(\mathbb{R}^2, \mathbb{R}^n) \) we denote by \( \| \cdot \|_{\ell,k}^A \) the following norm

\[
\| h \|_{\ell,k}^A = \sup_{x \in \mathbb{R}^2} \sum_{j=1}^{n} \sigma_j^2(h_j(x))^2 r_{\ell}(x)^2,
\]

where \( h \in C_0^0(\mathbb{R}^2, \mathbb{R}^n) \) and \( k, \ell \in \mathbb{R} \).

Lemma 1 Let \( \tilde{\psi}_n \) be a solution to the equation (11) then we have

\[
\| \tilde{\psi}_n \|_{\ell,-1}^A \lesssim \| \exp(\alpha \Xi_{\ell,n}(x)w(z)) u_{\ell,m(x)\neq 0} f(x)r_{\ell}(x) \|_{\infty} \tag{12}
\]

\[
\| (-\Delta_x + m^2 + \Sigma_n)(\tilde{\psi}_n) \|_{\ell,-1}^A \lesssim \| \exp(\alpha' \Xi_{\ell,n}(x)w(z) + \| \tilde{\psi}_n \|_{\ell,-1}^A r_{\ell}(x)) u_{\ell,m(x)\neq 0} f(x)r_{\ell}(x) \|_{\infty} \tag{13}
\]

where \( \Xi_{\ell,n} = \| P_n \xi^\alpha(x,z) \|_{C_0^0(\mathbb{R}^2) \otimes C_0^0(M)} \), \( \alpha, \alpha' \) and the implicit constants do not depend on \( n \).

Proof We write \( \tilde{\psi}_n = \left( \frac{\tilde{\psi}_n}{\mu_k} \right)_{k=1,...,n} \). The equation for \( \tilde{\psi}_n \) reads

\[
(-\Delta_x + m^2 + \lambda_k)(\tilde{\psi}_n)(x) + \mu_k f(x) \int_M g(z)H_k(z)V'(P_n \xi^A(x,z) + \tilde{\phi}_n(x,z))dz = 0
\]

where \( \tilde{\phi}_n(x,z) \) is related to \( \tilde{\psi}_n \) by

\[
\tilde{\phi}_n(x,z) = \sum_{k=1}^{n} \mu_k \tilde{\psi}_k(x)H_k(z).
\]

Putting \( \tilde{\Psi}_n^2(x) = (1 + \theta|z|)^{-2\ell} \sum_{k=1}^{n} (\tilde{\psi}_n^k(x))^2 \), writing \( r_{\ell,\theta}(x) = (1 + \theta|x|)^{-2\ell} \), for some \( \theta > 0 \), and denoting by \( \tilde{x} \) the maximum of \( \tilde{\Psi}_n \) we have

\[
m^2 \tilde{\Psi}_n^2(\tilde{x}) \leq \frac{1}{2} \Delta(\tilde{\Psi}_n^2)(\tilde{x}) + m^2 \tilde{\Psi}_n^2(\tilde{x}) + \tilde{\psi}_n(\tilde{x}) \cdot \Sigma_n(\tilde{\psi}_n(\tilde{x}))
\]

\[
\leq -r_{\ell,\theta} \tilde{\psi}_n \cdot \Delta \tilde{\psi}_n - r_{\ell,\theta} |\nabla \tilde{\psi}_n|^2 - \left( \frac{\| \nabla r_{\ell,\theta} \|^2 + \Delta r_{\ell,\theta}}{r_{\ell,\theta}^2} \right) \tilde{\Psi}_n^2(\tilde{x}) + m^2 \tilde{\psi}_n(\tilde{x}) + r_{\ell,\theta} \tilde{\psi}_n(\tilde{x}) \cdot \Sigma_n(\tilde{\psi}_n(\tilde{x}))
\]

\[
\leq -f(\tilde{x}) r_{\ell,\theta}(x) \int_M g(z) \tilde{\phi}_n(\tilde{x},z) V'(P_n \xi^A(\tilde{x},z) + \tilde{\phi}_n(\tilde{x},z))dz
\]

\[
- \left[ \frac{\| \nabla r_{\ell,\theta} \|^2 + \Delta r_{\ell,\theta}}{r_{\ell,\theta}^2} \right] \tilde{\Psi}_n^2(\tilde{x}), \tag{14}
\]

where we used that

\[
\nabla \left[ \sum_{k=1}^{n} (\tilde{\psi}_n^k(x))^2 \right] = -\frac{\nabla r_{\ell,\theta}(\tilde{x})}{r_{\ell,\theta}(\tilde{x})} \sum_{k=1}^{n} (\tilde{\psi}_n^k(\tilde{x}))^2
\]

since \( \tilde{x} \) is a stationary point for \( \tilde{\Psi}_n \). From equation (14) if, for any fixed \( \ell \), we choose a \( \theta \) in such a way that

\[
\left[ \frac{\| \nabla r_{\ell,\theta} \|^2 + \Delta r_{\ell,\theta}}{r_{\ell,\theta}^2} \right] \leq m^2
\]

12
we obtain
\[ \tilde{\Psi}_n^2(\bar{x}) \lesssim \|\exp(\alpha\Xi_{\nu',\nu'}(x)w(z))\|_\infty \cdot \|\hat{\phi}_n(x, z)\|_\infty \]
where all the constants do not depend on \( n \). On the other hand
\[ |\hat{\phi}_n(x, z)| \leq \sum_{k=1}^n |\hat{\psi}_n^k(x)| |H_k(z)| \]
\[ \lesssim \left\| \frac{1}{w(z)} \| y(z) \|_\infty \right\| \tilde{\Psi}_n(\bar{x}) \sum_{k=1}^\infty m_k \|\hat{H}_k(z)w(z)\|_2^2, \]
for all \( x \in \mathbb{R}^2 \) and \( z \in M \). Using Hypothesis H4 we deduce from this that
\[ \tilde{\Psi}_n(\bar{x}) \lesssim \|\exp(\alpha\Xi_{\nu',\nu'}(x)w(z))\|_\infty \cdot \|\hat{\phi}_n(x, z)\|_\infty. \]
Since \( \|\tilde{\psi}_n\|_{\ell,-1}^A \lesssim \|\tilde{\phi}_n\|_\infty \) inequality (12) is proved. Inequality (13) follows directly from inequality (12) and equation (4). \( \square \)

Corollary 1 Under the hypotheses and notations of Lemma 1 we have that there exists an increasing continuous function \( K : \mathbb{R}_+ \to \mathbb{R}_+ \) such that
\[ \|(-\Delta_x + m^2 + \mathcal{L})(\bar{\phi}_n)\|_H \lesssim K(\Xi_{\ell,n}), \]
with \( \Xi_{\ell,n} \) as in Lemma 1.

Proof The proof consists simply in noting that
\[ \|(-\Delta_x + m^2 + \mathcal{L})(\bar{\phi}_n)\|_H \lesssim \|(-\Delta_x + m^2 + \mathcal{L}_n)(\tilde{\psi}_n)\|_{\ell,-1}^A, \]
indeed
\[ \|(-\Delta_x + m^2 + \mathcal{L})(\bar{\phi}_n)\|_H^2 = \int_{M \times \mathbb{R}^2} (-\Delta_x + m^2 + \mathcal{L})(\mathcal{A}^{-1}(\bar{\phi}_n)(x, z))^2 \, dx \, dz \]
\[ \lesssim \sum_{k=1}^n \frac{1}{\sigma_k} \int_{\mathbb{R}^2} (-\Delta_x + m^2 + \lambda_k)(\tilde{\psi}_n)^2 \, dx \]
\[ \lesssim \left( \|(-\Delta_x + m^2 + \mathcal{L}_n)(\tilde{\psi}_n)\|_{\ell,-1}^A \right)^2 \int_{\mathbb{R}^2} (1 + |x|)^{2\ell} \, dx \]
which is finite whenever \( \ell < -1 \). \( \square \)

An important consequence of Corollary 1 is the following lemma.

Lemma 2 Let \( K \subset \mathcal{W} \) be a compact set, then \( \mathcal{R} = \bigcup_{n \in \mathbb{N}} T_{\ell,n}^{-1}(K) \) is precompact in \( \mathcal{W} \).

Proof We write \( T_n(\phi, w) = \hat{\phi} + U_n(\hat{\phi} + w) \). If \( w_{n,y} \in \mathcal{W} \) is solution to the equation \( T_n(w_{n,y}) = y \) then \( \hat{\phi}_{n,y} = w_{n,y} - y \) will be solution to the equation \( T_n(\hat{\phi}_{n,y} + y) = 0 \). This will implies that \( \hat{\phi}_{n,y} = \mathcal{I}(\hat{\phi}_{n,y}) \) is a solution to equation (4) for the realization of white noise \( \xi^A(y) \). By Corollary 1 we have that \( \|\hat{\phi}_{n,y}\|_H \lesssim K(\Xi_{\ell,n,y}) \). On the other hand we have the estimate
\[ \sup_{n \in \mathbb{N}} \Xi_{\ell,n,y} = \sup_{n \in \mathbb{N}} \|P_\mathcal{N} \xi^A(y)\|_{C^0(\mathbb{R}^2) \cap \mathcal{D}'(M)} \lesssim \sup_{n \in \mathbb{N}} \|P_\mathcal{N} \xi^A(y)\|_W \lesssim \|\xi^A(y)\|_W, \]
which implies that
\[ \sup_{n \in \mathbb{N}} \|\hat{\phi}_{n,y}\|_H \lesssim \sup_{n \in \mathbb{N},y \in K} K(\Xi_{\ell,n,y}) \lesssim \sup_{y \in K} \|\xi^A(y)\|_W = C_K < +\infty. \]
Letting \( \tilde{K} = \{ w \in \mathcal{W} ; \|w\| < C_K \} \) we have that \( \tilde{K} \) is compact in \( \mathcal{W} \) since the inclusion map \( i : \mathcal{H} \to \mathcal{W} \) is compact. This fact implies that \( \mathcal{R} \subset \tilde{K} + \tilde{K} \) is precompact since it is contained in the sum of two compact sets. \( \square \)
Lemma 3 The family \((\nu_n)\) of measures such that \(T_{n,*}(\nu_n) = \mu^A\) is tight.

Proof Let \(\overline{K}\) be a compact set such that \(\mu(\overline{K}) \geq 1 - \epsilon\) for a fixed \(0 < \epsilon < 1\), then, by Lemma 2, \(\mathcal{R} := \bigcup_{n \in \mathbb{N}} T_{n}^{-1}(\overline{K})\) is a compact set in \(\mathcal{W}\). This implies

\[
\nu_n(\mathcal{R}) \geq \nu_n(\bigcup_{i} T_{n}^{-1}(\overline{K})) \geq \nu_n(T_{n}^{-1}(\overline{K})) \geq \mu^A(\overline{K}) \geq 1 - \epsilon,
\]

for any \(n \in \mathbb{N}\). Thus the sequence \(\nu_n\) is tight and the lemma is proven.

Lemma 4 Suppose that \((\nu_n)\) is a sequence of weak solutions to equation (5) weakly converging to \(\nu\), then \(\nu\) is a solution to (1), i.e. \(T_*(\nu) = \mu^A\).

Proof Proving the claim is equivalent to prove that for any function \(h : \mathcal{W} \rightarrow \mathbb{R}\) which is bounded with continuous and bounded Fréchet derivative we have \(\int h \circ T d\nu = \int h d\mu^A\). In order to prove this we note that

\[
\|h \circ T(w) - h \circ T_n(w)\|_{\mathcal{W}} \leq \|h\|_{C^1(\mathcal{W})} : \|U(w) - P_n(U(P_n(w)))\|_{\mathcal{W}}.
\]

On the other hand we have

\[
\|U(w) - P_n(U(P_n(w)))\|_{\mathcal{W}} \leq \sum_{k=n}^{\infty} \sigma_k \|U(w)\|_{\mathcal{H}} + \sup_{w \in [w, P_n(w)]} \|\nabla U(y)\|_{\mathcal{L}(\mathcal{W})}\|P_n(w) - w\|_{\mathcal{W}}.
\]

Finally we observe that

\[
\|P_n(w) - w\|_{\mathcal{W}} = \|(I - P_n)(T_n(w))\|_{\mathcal{W}}.
\]

Let \(K_i \subset \mathcal{W}\) be a compact set such that \(\nu_n(\mathcal{W} \setminus K_i), \nu(\mathcal{W} \setminus K_i) < \epsilon\) then we have

\[
\left| \int_{\mathcal{W}} h \circ T d\nu - \int_{\mathcal{W}} h d\mu \right| \leq \left| \int_{\mathcal{W}} h \circ T d\nu - \int_{\mathcal{W}} h \circ T d\nu_n \right| + \left| \int_{\mathcal{W}} (h \circ T - h \circ T_n) d\nu_n \right| \\
\leq \left| \int_{\mathcal{W}} h \circ T d\nu - \int_{\mathcal{W}} h \circ T d\nu_n \right| + \epsilon \|h\|_{C^0(\mathcal{W})} \\
+ \left| \int_{K_i} (h \circ T - h \circ T_n) d\nu_n \right|.
\]

But

\[
\left| \int_{K_i} (h \circ T - h \circ T_n) d\nu_n \right| \leq \epsilon \sqrt{\sum_{k=n}^{\infty} \sigma_k \cdot \sup_{w \in K_i} \|U(w)\|_{\mathcal{H}} + \sup_{w \in K_i} \|\nabla U(w)\|_{\mathcal{L}(\mathcal{W})}} \\
\times \int_{\mathcal{W}} \|(I - P_n)(T_n(w))\|_{W} d\nu_n.
\]

On the other hand

\[
\int_{\mathcal{W}} \|(I - P_n)(T_n(w))\|_{\mathcal{W}} d\nu_n = \int_{\mathcal{W}} \|(I - P_n)(w)\|_{W} d\mu^A \leq \sum_{k=n}^{\infty} \sigma_k
\]

where we use that \(\mathbb{E}[\|(-\Delta + 1)^{-1}(\xi^b)^2\|_{C^0(\mathbb{R}^2) \cap W_1^{1, \nu}(\mathbb{R}^2)}^2]\) is equal to a finite constant independent on \(k\). Since \(\sum \sigma_k\) is convergent, we have that the right hand side of (17) converges to 0 as \(n \rightarrow +\infty\). Since \(U(w), \nabla U(w)\) are continuous with respect to \(w\), this implies that the right hand side of equation (16), converges to 0 as \(n \rightarrow +\infty\). Exploiting this fact, the fact that \(\nu_n\) weakly converges to \(\nu\) and equation (15) we obtain that \(\int_{\mathcal{W}} h \circ T d\nu - \int_{\mathcal{W}} h d\mu^A \leq \epsilon \|h\|_{C^0(\mathcal{W})}\). Since \(\epsilon > 0\) is arbitrary the lemma is proved.
Proof of Theorem 2. Thanks to Lemma 4 we have that the sequence of weak solutions $\nu_n$ satisfying the dimensional reduction principle (whose existence is proven by Proposition 2) converges weakly to a solution $\nu$ of the equation (10). If we are able to prove that $\Upsilon_{n,f} \nu_n \to \Upsilon_f \nu$ weakly, then the theorem would follow.

First of all we note that $\Upsilon_{n,f}(P_n(w))$ and that $\Upsilon_f$ is a bounded Fréchet $C^1(W)$ function. We want to prove that $\nabla \Upsilon_f(w)$ is bounded when $w$ is in a bounded set of $W$. We have that

$$\nabla \Upsilon_f(w)[h] = -\Upsilon_f(w) \int_{\mathbb{R}^2 \times M} f'(x)g(z)V'(\mathcal{I}(w)(x,z))(\mathcal{I}h)(x,z)dx dz.$$

In particular we have that

$$\|\nabla \Upsilon_f(w)\|_{W^*} \lesssim \int_{\mathbb{R}^2 \times M} f'(x)g(z)\exp(\alpha\|\mathcal{I}(w)\|_{C^0_\pi C^0_\pi(M)}(1 + |x|')\omega(z))dx dz,$$

for a suitable positive constant $\alpha$. On the other hand the linear map $\mathcal{I} : W \to C^0_\pi C^0_\pi(M)$ is continuous which implies that if $B$ is a bounded set of $W$ given by $\sup_{w \in B} \|\mathcal{I}(w)\|_{C^0_\pi C^0_\pi(M)} < +\infty$. This observation proves that $\sup_{w \in B} \|\nabla \Upsilon_f(w)\|_{W^*} < +\infty$ for any bounded set $B \subset W$.

Let for any given $\epsilon > 0$, $K_\epsilon \subset W$ be a compact set such that $\nu_n(\bigcup_{n \in \mathbb{N}} P_n(K_\epsilon)) < \epsilon$, then there exists a ball $B_\epsilon \subset W$ such that $K_\epsilon \cup (\bigcup_{n \in \mathbb{N}} P_n(K_\epsilon)) \subset B_\epsilon$. Let $F$ be a continuous and bounded function on $W$ then

$$\left| \int_W F(w) \Upsilon_{f,n} d\nu_n - \int_W F(w) \Upsilon_f d\nu \right| \leq \left| \int_W F(w)(\Upsilon_f(P_n(w)) - \Upsilon_f(w))d\nu_n \right| +$$

$$+ \left| \int_W F(w) \Upsilon_f d\nu_n - \int_W F(w) \Upsilon_f d\nu \right| \lesssim \epsilon + \|\nabla \Upsilon_f(w)\|_{C^1(B)} \int_W \|P_n(w) - w\|_W d\nu_n$$

$$\lesssim \epsilon + \|\nabla \Upsilon_f(w)\|_{C^1(B)} \int_W \|P_n(T_n(w)) - T_n(w)\|_W d\nu_n$$

$$+ \left| \int_W F(w) \Upsilon_f d\nu_n - \int_W F(w) \Upsilon_f d\nu \right| \to \epsilon,$$

as $n \to \infty$, where the constants implied in the symbol $\lesssim$ do not depend on $\epsilon$. For this reason since $\epsilon$ is arbitrary positive, $\int_W F(w) \Upsilon_{f,n} d\nu_n \to \int_W F(w) \Upsilon_f d\nu$ and the theorem is proven.

2.2 Dimensional reduction in the full space

In this section we consider the following equation

$$(-\Delta x - \Delta z + m^2)(\phi)(x, z) + A^2[f(x')g(z')V'(\phi(x', z'))](x, z) = \xi^A(x, z), \quad (18)$$

where $x, x' \in \mathbb{R}^2$ and $z, z' \in M$. We consider the following hypotheses on $\mathcal{L}$ and $A$ (in addition to the previous $Hf$ and $Hg$ on the cut-offs):

**Hypothesis $\mathcal{L}2$** $\mathcal{L} = -\Delta$ and $M = \mathbb{R}^d$

**Hypothesis $A1$** $A(h(z')) = a \ast h$ where $a(z)$ is a $C^{1+d/2}(\mathbb{R}^2)$ Hölder continuous function with compact support.

**Hypothesis $\xi1$** The noise $\xi^A$ is such that if $h_1, h_2 \in C^\infty_0(\mathbb{R}^2 \times \mathbb{R}^d)$ we have

$$\mathbb{E}[(h_1, \xi^A)(h_2, \xi^A)] = \int_{\mathbb{R}^2 \times \mathbb{R}^d} (I \otimes A)(h_1)(x, z)(I \otimes A)(h_2)(x, z) dx dz.$$
In this subsection we assume Hypotheses H−1, H−1 and H−1 instead of the corresponding assumptions H−, H− and H− respectively we had before. The assumptions Hf and Hg on the space cut-offs however remain.

We define the abstract Wiener space (W, H, μ−) relative to equation (15) as follows.

\[
\begin{align*}
H &= L^2(\mathbb{R}^2) \otimes_H \mathcal{A}(L^2(\mathbb{R}^d)) \\
W &= (-\Delta_x + 1)(C_0^0(\mathbb{R}^2) \cap W^{1,p}_\ell(\mathbb{R}^2)) \otimes_{\pi} C_0^{0}(\mathbb{R}^d)
\end{align*}
\]

where we suppose \(\ell, \ell' > 0\). The maps \(T\) and \(U\), and so the concept of weak and strong solution to equation (15), are defined in the same way as in the previous section. We shall prove the following theorem.

**Theorem 3** Suppose that \(V\) satisfies Hypothesis QC (in Section 2.1), then there exists a weak solution \(\nu\) to equation (15) such that for any Borel measurable function \(F : \mathbb{W} \to \mathbb{R}\)

\[
\int_W F(\mathcal{W}(0)) \mathcal{Y}_f(w) d\nu(w) = Z_f \int_W F(\omega) d\kappa(\omega),
\]

as in (10).

It is clear that the conditions H−1, H−1 on \(\mathcal{L}, M, \mathcal{A}\) are incompatible with the previous Hypotheses H− and H−. Thus Theorem 3 does not follow directly from Theorem 1. The rest of this subsection will focus on the proof of Theorem 3.

In order to achieve the proof we first replace \(M\) by the manifolds \(M_R = \mathbb{T}^d_R\), i.e. \(M_R\) is a torus of radius \(R > 0\). If \(h\) is a real-valued function on \(M = \mathbb{R}^d\) with sufficient decay at infinity we can easily define a function \(h_R\) on \(M_R\) in the following way

\[
h_R(z_R) = \sum_{j \in \mathbb{Z}^d} h(z_R + Rj)
\]

where \(z_R \in [-R/2, R/2]^d\). There is also a standard way of defining a function \(h_R\) on \(M_R\) given one on \(M\), that is the following

\[
\tilde{h}_R(z_R) = h(z_R).
\]

If the function \(h\) has support contained in \([-R/2, R/2]^d\) then \(\tilde{h}_R = h_R\).

On the other hand if we consider a function \(k : M_R \to \mathbb{R}\) we can associated with it a function \(k^R\) defined on all of \(M\) in the following way

\[
k^R(z) = k \left( -R + 2R \left( z - \left\lceil \frac{z}{2R} \right\rceil \right) \right),
\]

\(z \in M = \mathbb{R}^d\). In general we have that \((\tilde{k}^R)_R = k\), and so if \(k\) has compact support contained in \((-R/2, R/2)^d\) we have \(k = (k^R)_R\). Furthermore if \(b\) is a function with compact support on \(\mathbb{R}^d\) and \(k\) is a function on \(M_R\) we have \((b \ast k)^R = b \ast k^R\). Furthermore it is important to note that if \(\mathcal{G}_R\) is the Green function associated with the operator \((-\Delta_x - \Lambda + m^2)^{-1}\) on \(\mathbb{R}^2 \times M_R\) and \(\mathcal{G}\) is the Green function of the same operator on \(\mathbb{R}^2 \times M\) we have

\[
\mathcal{G}_R = \mathcal{G}_R.
\]

We define the operator \(\mathcal{A}_R\) on \(L^2(M_R)\) as \(\mathcal{A}_R(k) = a_R \ast k\). In this way we can define the abstract Wiener space \((W_R, H_R, \mu^{\mathcal{A}_R})\) as follows

\[
\begin{align*}
H_R &= L^2(\mathbb{R}^2) \otimes_H \mathcal{A}_R(L^2(M_R)) \\
W_R &= (-\Delta_x + 1)(C_0^0(\mathbb{R}^2) \cap W^{1,p}_\ell(\mathbb{R}^2)) \otimes_{\pi} \mathcal{A}_R^{1/2}(L^2(M_R))
\end{align*}
\]

and \(\mu^{\mathcal{A}_R}\) is the law of the noise \(\xi^A_R\) on \(W_R\) with covariance \(\mathcal{A}_R\).
Using the map $(\cdot)^p$ we can extend the noise $\xi_R^A$, defined on $M_R$, to the noise $\xi_R^{A,p}$ defined on all $M$. This means that the law $\mu_R^{A,p}$ of $\xi_R^{A,p}$ on $W_R$, thanks to the map $(\cdot)^p$, induces a Gaussian measure $\mu_R^{A,p}$ on $W$, which is the measure of the noise $\xi_R^{A,p}$. It is simple to prove that $\mu_R^{A,p}$ weakly converges to $\mu^A$ when $R \to +\infty$ and the support of $A$ is compact.

Let $U_R : W_R \to H_R$ be the function defined by

$$U_R(w_R) := f(x)A_R(g_R(z_R)V'(\mathcal{G}_R* w_R)) = f(x)A_R(g_R(z_R)V'(\mathcal{G}_R* w_R)).$$

We set $T_R(w_R) = w_R + U_R(w_R)$. The map $U_R$ induces a map $U_R^p$ on $W$ in the following way

$$U_R^p(w) = f(x)A_R(g_R^p(z_R)V'(\mathcal{G}_R* w_R^p)),$$

and $T_R^p(w) = w + U_R^p(w)$. Let $\nu_R$ be a probability law on $W_R$ such that $T_R, (\nu_R) = \mu_R^{A,p}$, then it induces a probability law $\nu_R^p$ on $W$ such that $T_R^p (\nu_R^p) = \mu_R^{A,p}$.

**Lemma 5** Let $R_n \in \mathbb{R}_+$ be a sequence such that $R_n \to +\infty$, then the sequence $\nu_R^p$ is tight on $W$ and if $\nu_R^p \to \nu$, as $n \to +\infty$ and $R_n \to +\infty$, then $T_* (\nu) = \mu^A$.

**Proof** We note that the support of $\nu_R^p$ is contained in the set of $R_n$ periodic distributions contained in $W$ and furthermore the map $T_R^p$ sends $R_n$ periodic distributions into $R_n$ periodic distributions.

Using the methods of Lemma 1 and Corollary 1 it is simple to prove that if $y_n \in W$ is an $R_n$ periodic distribution and if $w_{y_n} \in W$ is an $R_n$ periodic distribution such that $w_{y_n} \in T_R^{p_n-1}(y_n)$ then

$$\|w_{y_n} - y_n\| \leq K_{f,g}(\mathcal{X}_{t,p}(y_n)),$$

where

$$\mathcal{X}_{t,p}(y_n) = \sup_{(x,z) \in \mathbb{R}^2 \times M} |\mathcal{G}* y_n(x,z)| \rho(x) \rho_V(z),$$

and $K_{f,g}$ is a positive increasing continuous function depending only on the functions $f$ and $g$. It is simple to prove that the map $\mathcal{X}_{t,p}$ is continuous on $W$. Using the fact that, as $n \to +\infty$ and $R_n \to +\infty$, $\mu_R^{A,p}$ converges to $\mu^A$ weakly and so the sequence $\mu_R^{A,p}$ is tight, we can use the bound (19) and the same methods of Lemma 3 to prove that $\nu_R^p$ is tight.

Suppose that $\nu_R^p$ weakly converges to $\nu$, we want to prove that $T_* (\nu) = \mu^A$. Let $F_R$ be a function of the form $F_R(w) = G((h_1,w),\ldots,(h_r,w))$, where $G : \mathbb{R}^r \to \mathbb{R}$ is a continuous and bounded function and $h_1,\ldots,h_r$ are smooth functions with support in $(-R/2 + t, R/2 - t)^n$ and $t = \text{diam}(\text{supp}(A))$. For this kind of function we have that $F_R \circ T_R^k = F_R \circ T$ for $k \geq n$. From this observation we get

$$\int F_R \circ T \text{d}\nu = \lim_k \int F_R \circ T \text{d}\nu_R^p = \lim_k \int F_R \circ T_R^k \text{d}\nu_R^p = \lim_k \int F_R \text{d}\mu_R^{A,p} = \int F_R \text{d}\mu^A,$$

where the limit is taken for $k \to +\infty$ and $R_k \to +\infty$. Since the functions of the form $F_R$, for $n \in \mathbb{N}$, generate the space of all $W$ Borel measurable functions the Lemma is proved.

**Proof of Theorem 3** By Theorem 2 there exists a probability law $\nu_R$ on $W_R$ such that $T_{R_n,*}(\nu_R) = \mu_R^{A,p}$. On the other hand this implies that $T_R^{p_n*(\nu_R^p)} = \mu_R^{A,p}$ and so, by Lemma 5 there exists at least one probability measure $\nu$ on $W$ such that $T_* (\nu) = \mu^A$ and $\nu_R^p \to \nu$ weakly, as $n \to +\infty$.

Then, using the notations of the proof of Lemma 5 we have that for any continuous function $F_R : W \to \mathbb{R}$

$$\int_W F_R(G*w(0,z))T_f(w) \text{d}\nu_R^p(w) = \int_W F_R(\omega) \text{d}\nu_R^p(\omega),$$

where we used that

$$\int_W F_R(G*R(w_R(0,z))T_f(w_R(0,z)) \text{d}\nu_R^p(w_R) = \int_W F_R(G*w(0,z))T_f(w) \text{d}\nu_R^p(w),$$

17
for $k \geq n$ and a similar equality for $\kappa_{R_k}$. Since $F_{R_k}(G^*)$ and $\Upsilon_f$ are continuous on $\mathcal{W}$, the left
hand side of (20), converges to $\int_{\mathcal{W}} F_{R_n}(G^*)w(0,z))\Upsilon_f(w)\,dw$ as $k \to +\infty$.

Furthermore, since
\[
\frac{d\kappa_{R_k}}{d\mu^{A_{R_k},p}} = \sum_{j=1}^{n} \exp\left( -\frac{1}{\kappa_{R_k}} \int_{\mathbb{R}^2} g(z)\nu(z)\,dz \right)
\]
and since $\mu^{A_{R_k},p}$ weakly converges to $\mu^{A_*}$, we have that $\kappa_{R_k}$ weakly converges to $\kappa$, as $k, R_k \to \infty$. This proves that the right hand side of (20) converges to $\int_{\mathcal{W}} F_{R_n}(\omega)\,d\kappa(\omega)$, as $k, R_k \to \infty$. Since the functions of the form $F_{R_n}$, for $n \in \mathbb{N}$, generate the space of $\mathcal{W}$ measurable functions, the theorem is proved. \hfill $\square$

2.3 Cut-off removal with convex potential

Hereafter we denote by $\omega_\beta(x)$ the function
\[
\omega_\beta(x) := \exp(-\beta \sqrt{(1 + |x|^2)}),
\]
$\beta > 0$, $x \in \mathbb{R}^2$, and introduce the space $\mathcal{W}_\beta$ in the following way
\[
\mathcal{W}_\beta := (-\Delta + 1)\mathcal{C}_{\exp, \beta}^0(\mathbb{R}^2) \otimes \mathcal{A}^{1/2}(L^2(M))
\]
where $\mathcal{C}_{\exp, \beta}^0$ is the space of continuous functions with respect to the weighted $L^\infty$ norm
\[
\|g\|_{\infty, \exp, \beta} := \sup_{x \in \mathbb{R}^2} |\omega_\beta(x)g(x)|.
\]
In this section we want to prove the following theorem.

**Theorem 4** Suppose that $V$ is a convex function, and suppose that $\mathcal{A}$, and $\mathcal{L}$ satisfy Hypotheses $\mathcal{H}_A$, $\mathcal{H}_\mathcal{L} \mathcal{H}_\mathcal{X}$ (or Hypotheses $\mathcal{H}_A 1$, $\mathcal{H}_\mathcal{L} 1$ and $\mathcal{H}_\mathcal{X} 1$) then there exists a unique strong solution $\phi(x, z)$ to equation (11) (or to equation (13)) with $f \equiv 1$ taking values on $\mathcal{W}_\beta$ (for a $\beta \leq \beta_0$ which depends only on $m^2$) such that for any $\mathcal{W}$ measurable bounded function $F$ we have
\[
\mathbb{E}[F(\phi(0, z))] = \int_{\mathcal{W}} F(\omega)\,d\kappa(\omega)
\]
($\kappa$ as in equation (11)).

The proof is very similar to those of Theorem 2 and Theorem 3. For this reason we report here only the main differences. First of all we need a replacement for Proposition 2.

**Proposition 3** Let $V$ (and so $V_n$) be a convex function then under assumptions $\mathcal{H}_\mathcal{L}$, $\mathcal{H}_A$ and $\mathcal{H}_\mathcal{X}$ there exists a unique strong solution $\phi_n$ to equation (13) such that for all $\mathcal{W}$ measurable bounded function $F$ we have
\[
\mathbb{E}[F(\phi_n(0, z))] = \int_{\mathcal{W}} F(\omega)\,d\kappa_n(\omega)
\]
where $\kappa_n$ is given by expression (8).

**Proof** The proof is given in [11], Theorem 2 in the case $\mathcal{L}_n = 0$. The case considered here is a trivial extension. \hfill $\square$

In order to pass from equation (23) to equation (22) we need a generalisation of Lemma 1. We denote by $\|\cdot\|_{\exp, \beta, \ell}$ and $\|\cdot\|_{\mathcal{A}, \ell}$ the following norms
\[
\|h\|_{\exp, \beta, \ell} := \sup_{x \in \mathbb{R}^2} \sqrt{\sum_{j=1}^{n} \sigma_j^2(h(x))^2 \omega_\beta(x)^2},
\]
\[
\|h\|_{\mathcal{A}, \ell} := \sup_{x \in U} \sqrt{\sum_{j=1}^{n} \sigma_j^2(h(x))^2}.
\]
Lemma 6 There exists a number $\beta_0 > 0$ such that for any $0 < \beta \leq \beta_0$, and for any open bounded set $U \subset \mathbb{R}^2$ and under Hypotheses C, Hg, HA, Hξ and $f \equiv 1$ we have

\[
\|\psi_n\|^4_{\exp, -1} \leq \|\exp(\alpha\Xi_{\ell,n}\rho_E(x)w(z))\|_{\infty}
\]

(24)

\[
\|(-\Delta_x + m^2 + \Sigma_n)(\psi_n)\|^2_{\exp, -1} \leq \|\exp(\alpha'(\Xi_{\ell,n}w(z)) + \|\psi_n\|^4_{\exp, -1})\omega_\beta(x)\|_{C^0(U)}
\]

(25)

uniformly in $n$ (where $\Xi_{\ell,n}$ is defined as in Lemma 1).

Proof The proof is verbatim the same of Lemma 1 where we replace the function $\rho_E(x) = (1 + \theta|x|)^{\ell}$ by the function $\omega_\beta$, defined as in the beginning of the section, and we use the fact for $\beta$ small enough we have

\[
\left(\frac{1}{\omega_\beta^2} + \frac{\Delta \omega_\beta}{\omega_\beta}\right) < m^2.
\]

\[
\left\langle \frac{1}{\omega_\beta^2} + \frac{\Delta \omega_\beta}{\omega_\beta}\right\rangle < m^2.
\]

(26)

The inequality (26) implies that, for any bounded open subset $U$ of $\mathbb{R}^{2+d}$ we have

\[
\|(-\Delta_x + m^2 + \Sigma)(\psi_n)\|_{\mathcal{H}_U} \leq K_U(\Xi_{\ell,n})
\]

where $\| \cdot \|_{\mathcal{H}_U}$ is the natural norm of the Hilbert space $\mathcal{H}_U = L^2(U) \otimes_H A(L^2(M))$, and $K_U$ is a positive increasing continuous function depending only on $U$. Inequality (26) guarantees us enough compactness to generalise Lemma 2, Lemma 3 and Lemma 4 in order to prove the existence of a weak solution to equation (1) satisfying the dimensional reduction principle when $f \equiv 1$ and under Hypotheses C, Hg, HA, Hξ. We can generalise the described result under Hypotheses C, Hg, Hξ, Hξ. We give here only a sketch of the proof.

In this section we want to consider the following elliptic SPDE

\[
\begin{align*}
\left\langle -\Delta_x + m^2 - V(x), \phi \right\rangle + g(x) \exp(\alpha \phi - \infty) = \xi
\end{align*}
\]

(27)
where \( x \in \mathbb{R}^2, z \in M = \mathbb{R}^2 \) and \( \xi = \xi(x, z) \) is a standard Gaussian white noise on \( \mathbb{R}^4 \) \(|\alpha| < 4\sqrt{2}\pi\), and where \(-\infty \) means that the equation should be properly renormalised. In order to give a meaning to the previous equation we formally subtract from the solution \( \tilde{\phi} \) the solution to the linear equation (i.e. equation (27) with \( g = 0 \)) which means that we consider the equation for the unknown \( \tilde{\phi} \):

\[
(-\Delta_x - \Delta_z + m^2)(\tilde{\phi}) + g(z)\alpha \exp(\alpha \tilde{\phi})\eta(x, z) = 0, \tag{28}
\]

where \( \eta(x, z) = \exp^\phi(\xi) \) is a renormalised version of the distribution \( \exp(\alpha \xi - \infty) \), where \( \exp^\phi \) denotes the Wick exponential of the Gaussian distribution \( \mathcal{I} \xi \). Hereafter we denote by \( B^s_{p,q,\ell}(\mathbb{R}^{d+2}) \) the weighted Besov space of indices \( 1 \leq p \leq \infty \) and \( 1 \leq q \leq \infty \) and weight given by \( p_T(x, z) = \left( \sqrt{|x|^2 + |z|^2} + 1 \right)^{-\ell} \) (see [70]). It is well known that \( \mathcal{I} \xi \in B^s_{p,p,\ell} \) for any \( 1 \leq p \leq \infty \) and \( \delta > 0 \) (see e.g. [46]).

In the following we shall give a rigorous meaning to equation (28) (and so to equation (27)) when the exponent \(|\alpha| < 4\sqrt{2}\pi\) and, when \( \alpha \tilde{\phi} \leq 0 \), prove that there exists only one solution to equation (24).

Furthermore we want to prove that dimensional reduction holds for the unique solution to equation (27), namely that, if we consider the measure \( \kappa_x \) given by

\[
\frac{d\kappa_x}{d\mu} = \exp \left( -4\pi \int_{\mathbb{R}^2} g(z) \exp^\phi(\alpha \omega)(dz) \right), \tag{29}
\]

where \( \omega \in B^s_{p,p,\ell}(\mathbb{R}^2) \) and where \( \mu \) is the law of \((-\Delta_x + m^2)^{-1/2}(\xi)\) on \( B^s_{p,p,\ell}(\mathbb{R}^2) \), we have

\[
\mathbb{E}[F(\phi(0, \cdot))] = \int F(\omega) d\kappa_x(\omega),
\]

for any bounded measurable function defined on \( B^s_{p,p,\ell}(\mathbb{R}^2) \).

In order to prove the existence and uniqueness of the solution \( \tilde{\phi} \) to equation (28) and dimensional reduction (3) for the random field \( g \) linear equation (i.e. equation (27) with \( g \)) we need to introduce the following two approximate equations

\[
(-\Delta_x - \Delta_z + m^2)(\phi_x) + a_x^2 \gamma[g(z)\alpha \exp(\alpha \tilde{\phi} - C_x)] = a_x \xi \tag{30}
\]

\[
(-\Delta_x - \Delta_z + m^2)(\tilde{\phi}_x) + a_x^2 \gamma[g(z)\alpha \exp(\alpha \tilde{\phi}_x)\eta(x, z)] = 0 \tag{31}
\]

where \( a \) is a positive function satisfying Hypothesis HA1 (see Section 2.3) and \( C_x := \frac{\gamma}{2} \mathbb{E}[\mathcal{I}(a_x \xi) \Gamma^\phi(\alpha \mathcal{I}(a_x \xi)] \), \( \tilde{\phi}_x := \phi_x - \mathcal{I}(a_x \xi), \eta_x := \exp^\phi(\alpha \mathcal{I}(a_x \xi)) \) and \( \phi_x = \phi_x - a_x \mathcal{I} \xi \). The constant \( C_x \) is chosen in such a way that \( \eta \rightarrow \eta \) in \( B^s_{p,p,\ell} \) for suitable \( s < 0, 1 < p \leq 2 \) and \( \delta > 0 \) (see Section 3.1).

For equations (30) and (31) we have the following fundamental dimensional reduction result.

**Theorem 5** Equation (31) admits a unique solution in \( C^0_t(\mathbb{R}^4) \) for \( \ell \) big enough. Furthermore we have that, for any \( \epsilon > 0 \),

\[
\mathbb{E}[F(\phi_x(0, z))] = \int \mathbb{E}[F(\phi_x(0, z))] d\kappa_x(\omega), \tag{32}
\]

for all \( z \in \mathbb{R}^2 \), where

\[
\frac{d\kappa_x}{d\mu_x} = \exp \left( -4\pi \int_{\mathbb{R}^2} g(z) \exp(\alpha \omega(z) - \alpha C_x)dz \right)
\]

and \( \mu_x \) is the Gaussian measure on \( C^0_t(\mathbb{R}^4) \) with covariance \( \mathbb{E}[, \xi x \omega(z')] = a_x^2 \Gamma_z(z - z') \), where \( \Gamma_z \) is the Green function of the operator \((-\Delta_x + m^2) \). Finally the unique solution to equation (31) satisfies \( \alpha \tilde{\phi}_x \leq 0 \).
that \( \phi \) of all we note that

In this subsection we propose an analysis of the regularity of the noise \( \eta \) and we are able to prove that there exists a subsequence of \( \eta_n \) for which the symbol \( \phi_{\epsilon_n} \to \phi \) in probability in \( B_{p,p} \). This fact will permit us to prove equality (3).

### 3.1 Probabilistic analysis

In this subsection we propose an analysis of the regularity of the noise \( \eta \) and \( \eta_{\epsilon} \), for \( \epsilon > 0 \). First of all we note that

\[
\eta_{\epsilon} = \sum_{k=0}^{\infty} \frac{\alpha^k}{k!} (\mathcal{I}_\epsilon)^\otimes k,
\]

(33)

\[
\eta = \sum_{k=0}^{\infty} \frac{\alpha^k}{k!} (\mathcal{I})^\otimes k,
\]

(34)

where

\[
(\mathcal{I}_\epsilon)^\otimes k = \underbrace{\mathcal{I}_\epsilon \circ \ldots \circ \mathcal{I}_\epsilon}_{k \text{ times}},
\]

the symbol \( \otimes \) denotes the Wick product, \( \xi = a_{\epsilon} \ast \xi \) and \( \mathcal{I}_\epsilon \) is defined correspondingly. The previous expressions are well defined as \( L^2(\mu) \) convergent series for \( |\alpha| < 4\sqrt{2}\pi \). Indeed we have that for any smooth function \( g \) exponentially decaying at infinity

\[
\mathbb{E}[|\langle \eta_{\epsilon}, g \rangle|^2] = \int_{\mathbb{R}^4} g(\hat{z})g(\hat{z}') \exp(\alpha^2 G_{\epsilon}(\hat{z} - \hat{z}'))d\hat{z}d\hat{z}'
\]

(35)

where, hereafter, we write \( G_{\epsilon} = a_{\epsilon}^2 \ast G \), where \( G \) is the Green function associated with the operator \( (-\Delta_{\hat{z}} + m^2)^{-2} \), \( \hat{z} = (x, z) \in \mathbb{R}^4 \). It is well known (see Proposition A.1 of [9]) that for \( \hat{z} \in \mathbb{R}^4 \) such that \( |\hat{z}| \leq 1 \) there exists a constant \( C_1 > 0 \) for which the following inequality holds

\[
G(\hat{z}) = -\frac{2}{(4\pi)^2} \log(|\hat{z}|) + C_1.
\]

(36)

Furthermore for \( |\hat{z}| \geq 1 \) there exists two constants \( C_2, C_3 \) for which we get

\[
G(\hat{z}) \leq C_2 \exp(-C_3|\hat{z}|).
\]

(37)

An easy consequence of the inequalities (36) and (37) are the following inequalities

\[
a_{\epsilon}^2 \ast G(\hat{z}) \leq -\frac{2}{(4\pi)^2} \log(|\hat{z}|) + C_4,
\]

(38)

when \( 4 \text{diam(supp}(a)) \epsilon \leq |\hat{z}| \leq 1 \) and for some constant \( C_4 > 0 \);

\[
a_{\epsilon}^2 \ast G(\hat{z}) \leq -\frac{2}{(4\pi)^2} \log(\epsilon) + C_5,
\]

(39)

when \( |\hat{z}| < 2 \text{diam(supp}(a)) \epsilon \) and for some constant \( C_5 > 0 \); and finally

\[
a_{\epsilon}^2 \ast G(\hat{z}) \leq C_6 \exp(-C_7|\hat{z}|),
\]

(40)

when \( |\hat{z}| \geq 1 \) and for some constants \( C_6, C_7 > 0 \). It is important to note that the constants \( C_4, C_5, C_6, C_7 \) are independent of \( \epsilon \). The previous inequalities and eq. (35) imply that \( \mathbb{E}[|\langle \eta_{\epsilon}, g \rangle|^2] < +\infty \) for any \( \epsilon \geq 0 \) and \( |\alpha| < 4\sqrt{2}\pi \) (with \( \eta_0 = \eta \)).
This means that, if we denote by $D_k$ the $k \geq -1$ Littlewood-Paley block (see Appendix A for the definition of this concept), using the fact that $D_k$ exponentially decreases at infinity, we get

$$\mathbb{E}[|\langle \eta, D_k(\hat{z} - \cdot) \rangle|^2_{L^2_{\mathbb{R}^4}}] = \int_{\mathbb{R}^4} \mathbb{E}[|\langle \eta, D_k(\hat{z}) \rangle|^2](1 + |\hat{z}|)^{2\alpha}d\hat{z} \lesssim \mathbb{E}[|\langle \eta, D_k \rangle|^2] < +\infty,$$

whenever $\alpha < 4\sqrt{\pi}$. Since $D_k(x, z) = 2^{sk}D_0(2^k x, 2^k z)$ and using (35) and (37), we obtain

$$\mathbb{E}[|\langle \eta, D_k \rangle|^2] \lesssim \int_{\mathbb{R}^4} D_k(\hat{z})D_k(\hat{z}')\exp(\alpha^2 \cdot \alpha^2 s^2 G(\hat{z} - \hat{z}'))d\hat{z}d\hat{z}'$$

$$\lesssim \int_{\mathbb{R}^4} D_k(\hat{z})D_k(\hat{z}')|\hat{z} - \hat{z}'|^\frac{2\alpha^2}{\alpha^2 + 2\alpha}d\hat{z}d\hat{z}' +$$

$$+ \left(1 + \epsilon^4 - \frac{2\alpha^2}{\alpha^2 + 2\alpha}\right) \int_{\mathbb{R}^4} D_k(\hat{z})D_k(\hat{z}')d\hat{z}d\hat{z}'$$

$$\lesssim 2^{\frac{2\alpha^2}{\alpha^2 + 2\alpha}k} \left(\int_{\mathbb{R}^4} D_0(\hat{z})D_0(\hat{z}')d\hat{z}d\hat{z}'\right) \lesssim 2^{\frac{2\alpha^2}{\alpha^2 + 2\alpha}k}$$

where all the constants implied in the symbol $\lesssim$ are independent of $\epsilon$. This means that

$$\mathbb{E}[||\eta_k||^2_{B^2_{2,2,\epsilon}}] \lesssim \sum_{k=1}^{+\infty} 2^{\frac{2\alpha^2}{\alpha^2 + 2\alpha}k + 2sk},$$

which is finite and uniformly bounded in $\epsilon$ whenever $s < -\frac{\alpha^2}{(4\pi)^2}$ and for $\ell > 0$ large enough. Furthermore we have that

$$\mathbb{E}[||\eta - \eta_k||^2_{B^2_{2,2,\epsilon}}]^{1/2} \lesssim \left(\sum_{k=1}^{+\infty} 2^{sk}\mathbb{E}[||\langle \eta - \eta_k, D_k \rangle|^2]\right)^{1/2}$$

$$\lesssim \sum_{k=1}^{+\infty} 2^{sk}\sum_{n=0}^{+\infty} \frac{a_n}{n!}\mathbb{E}[||\langle \xi^n - \xi^n, D_k \rangle|^2]^{1/2}$$

for $\ell$ big enough. On the other hand, from the previous estimate, we get

$$\sum_{k=-1}^{+\infty} 2^{sk}\sum_{n=0}^{+\infty} \frac{a_n}{n!}\mathbb{E}[||\langle \xi^n - \xi^n, D_k \rangle|^2]^{1/2} \lesssim \sum_{k=1}^{+\infty} 2^{sk}\sum_{n=0}^{+\infty} \frac{a_n}{n!}\mathbb{E}[||\langle \xi^n - \xi^n, D_k \rangle|^2]^{1/2} +$$

$$+ \sum_{k=-1}^{+\infty} 2^{sk}\sum_{n=0}^{+\infty} \frac{a_n}{n!}\mathbb{E}[||\langle \xi^n - \xi^n, D_k \rangle|^2]^{1/2} < C,$$

for some constant $C > 0$ independent of $\epsilon$, whenever $s < -\frac{\alpha^2}{(4\pi)^2}$. Furthermore, since $a_\epsilon$ is a regular mollifier and by the properties of Wick product, we obtain

$$\mathbb{E}[|\langle \xi^n - \xi^n, D_k \rangle|^2] \to 0,$$

as $\epsilon \to 0$ and for any $k \geq -1$. The above inequality, together with the Lebesgue dominated convergence theorem, implies that

$$\mathbb{E}[||\eta - \eta_k||^2_{B^2_{2,2,\epsilon}}]^{1/2} \to 0,$$

when $\epsilon \to 0$ for any $\ell > 0$ large enough. We have thus proven the following lemma.

**Lemma 7** For $|\alpha| < 4\sqrt{\pi}$ and $s < -\frac{\alpha^2}{(4\pi)^2}$ and $\ell$ large enough we have that $\eta_k \to \eta$ as $\epsilon \to 0$ in $L^2(\mathcal{W}; B^2_{2,2,\epsilon}(\mathbb{R}^4), d\mu)$ and thus in probability in $B^2_{2,2,\epsilon}(\mathbb{R}^4)$.

We want to use the previous lemma to prove the following theorem.
Theorem 6  For $|\alpha| < 4\sqrt{2}\pi$, $1 < p \leq 2$, $s < -\frac{\alpha^2(p-1)}{4\pi^2}$ and $\ell$ large enough we have that $\eta_\epsilon \to \eta$, as $\epsilon \to 0$, in $L^p(W, B^s_{p,p,\ell}(\mathbb{R}^4), d\mu)$ and thus in probability in $B^s_{p,p,\ell}(\mathbb{R}^4)$.

In order to prove Theorem 6 we introduce the following lemma.

Lemma 8  Let $B_r(z)$ be the ball of radius $r$ and centre in $z \in \mathbb{R}^4$ then for any $r < R$, and for any $1 < p < 2$

$$
\mathbb{E} \left[ \left( \int_{B_r(z)} d\eta_{\epsilon} \right)^p \right] \lesssim r^{-\frac{2}{4\pi^2}p(p-1)+4p}
$$

where the constants depend only $R$ and it is uniform on $\epsilon \to 0$ and $|\alpha| < 4\sqrt{2}\pi$.

Proof The proof can be found in Proposition 2.7 of [64]. □

Proof of Theorem 6  First of all we have that, for any $\epsilon > 0$ and $k \geq 0$,

$$
\mathbb{E}[\|\langle \eta_{\epsilon}, D_k(z-\cdot) \rangle\|^p_{L^p_k}] = \int_{\mathbb{R}^4} \mathbb{E}[\langle \eta_{\epsilon}, D_k \rangle]^p (1 + |z|)^{p\rho} d\tilde{z} \lesssim \mathbb{E}[\langle \eta_{\epsilon}, D_k \rangle]^p.
$$

Then

$$
\mathbb{E}[\langle \eta_{\epsilon}, D_k \rangle]^p \lesssim \mathbb{E} \left[ \left( \int_{B_{r_k}(0)} D_k(z) d\eta_{\epsilon}(\tilde{z}) \right)^p \right] + \mathbb{E} \left[ \left( \int_{\mathbb{R}^4 \setminus B_{r_k}(0)} D_k(z) d\eta_{\epsilon}(\tilde{z}) \right)^p \right]^{2/p}.
$$

If we choose $r_k = 2^{-k} \log(2\beta k)$, from Lemma 8 we have, for any $k \geq 0$,

$$
\mathbb{E} \left[ \left( \int_{B_{r_k}(0)} D_k(z) d\eta_{\epsilon}(\tilde{z}) \right)^p \right] \lesssim 2^{4kp} \left( \frac{\alpha^2}{4\pi^2} p(p-1)-4pk \right) \log(2\beta p(p-1)-4pk).
$$

Furthermore, if we denote by $\gamma > 0$ the real number such that $D_0(\tilde{z}) \lesssim \exp(-\gamma|\tilde{z}|)$, we obtain

$$
\mathbb{E} \left[ \left( \int_{\mathbb{R}^4 \setminus B_{r_k}(0)} D_k(z) d\eta_{\epsilon}(\tilde{z}) \right)^p \right] \lesssim 2^{4\gamma p} \int_{\mathbb{R}^4} \exp(-\gamma(|\tilde{z}| + |\tilde{z}'|)) + \alpha^2 G_\alpha(z - z') d\tilde{z} d\tilde{z}' \lesssim 2^{4\gamma p} k.
$$

If we choose $\beta$ such that $4 - \gamma \beta < \frac{\alpha^2}{4\pi^2} p(p-1)$ we obtain that

$$
\mathbb{E}[\langle \eta_{\epsilon}, D_k \rangle]^p \lesssim 2^{\frac{\alpha^2}{4\pi^2} p(p-1)-4pk} \log(2\beta p(p-1)-4pk)
$$

uniformly in $\epsilon$. This implies that $\mathbb{E}[\|\langle \eta_{\epsilon}, D_k \rangle\|^p_{L^p_k}]$ is bounded for $s < \frac{\alpha^2}{4\pi^2} p(p-1)$ uniformly in $\epsilon > 0$.

Furthermore, by Lemma 7 $\mathbb{E}[\|\langle \eta_{\epsilon}, D_k \rangle\|^p_{L^p_k}]$ is uniformly bounded. This means that the random variables $\|\langle \eta_{\epsilon}, D_k \rangle\|^p$ (for $p < 2$) are uniformly integrable. On the other hand, by Lemma 7 and since $D_k \in B^{2\ell}_{p,p,\ell}([\langle \eta_{\epsilon}, D_k \rangle]^p$ converges to $\|\langle \eta, D_k \rangle\|^p$ in probability, we have that $\mathbb{E}[\|\langle \eta_{\epsilon}, D_k \rangle\|^p] \to \mathbb{E}[\|\langle \eta, D_k \rangle\|^p]$. Thus by the bound (21) we can use the Lebesgue dominated convergence theorem for computing the limit of $\mathbb{E}[\|\langle \eta_{\epsilon} \rangle\|^p_{L^p}]$, obtaining

$$
\mathbb{E}[\|\langle \eta_{\epsilon} \rangle\|^p_{L^p}] \to \mathbb{E}[\|\langle \eta \rangle\|^p_{L^p}],
$$

as $\epsilon \to 0$. But, since $\mathbb{E}[\|\langle \eta_{\epsilon} \rangle\|^p_{L^p}]$ is uniformly bounded and since, by Lemma 7 as $\epsilon \to 0$, $\eta_{\epsilon} \to \eta$ in probability in $B^{2\ell}_{p,p,\ell}$, we have that $\eta_{\epsilon}$ converges weakly to $\eta$ in $L^p(W, B^s_{p,p,\ell}, d\mu)$. Since $L^p(W, B^s_{p,p,\ell}, d\mu)$ is a uniformly convex space, being the space of $L^p$ functions taking values in the uniformly convex space $B^s_{p,p,\ell}$ (see [31]), by the weak convergence $\eta_{\epsilon} \to \eta$ and the convergence of the $L^p$ norm $\mathbb{E}[\|\langle \eta_{\epsilon} \rangle\|^p_{L^p}] \to \mathbb{E}[\|\langle \eta \rangle\|^p_{L^p}]$, we obtain that $\eta_{\epsilon}$ converges strongly to $\eta$ in $B^s_{p,p,\ell}(\mathbb{R}^4)$, as $\epsilon \to 0$. □
3.2 Analysis of the elliptic SPDE

In this section we want to prove the following theorem.

**Theorem 7** For any $|a| < 4\sqrt{2}\pi$, $1 < p \leq 2$ such that $p < \frac{2(4\pi)^2}{\alpha^2}$ and $s < 0$ such that $-\frac{2(p-1)}{p} < s < -\frac{\alpha^2(p-1)}{(4\pi)^2}$ we have that equation $(28)$ admits a unique solution in $B^{s+2}_{p,p,\ell}$ for $\ell$ large enough and such that $\alpha \delta \leq 0$. Furthermore we have that there exists a subsequence $\varepsilon_n \to 0$ such that $\hat{\phi}_{n} \to \hat{\phi}$ in $B^{s+2-\delta}_{p,p,\ell+\delta'}$ (for some $\delta, \delta' > 0$ small enough), as $n \to \infty$, almost surely.

Hereafter, for $t > 0$, we write $B^{t}_{p,p,\ell}(\mathbb{R}^3) = B^{t}_{p,p,\ell}(\mathbb{R}^3) \cap L^{\infty}(\mathbb{R}^3)$. The space $B^{t}_{p,p,\ell}$ has a natural norm given by the sum of the norms of $B^{t}_{p,p,\ell}(\mathbb{R}^3)$ and $L^{\infty}(\mathbb{R}^3)$. Furthermore we can equip the space $B^{t}_{p,p,\ell}$ with a different notion of convergence of sequences: we say that a sequence $h_n \in B^{t}_{p,p,\ell}$ pseudoconverges to $h \in B^{t}_{p,p,\ell}$ if $h_n$ converges to $h$ strongly in $B^{t}_{p,p,\ell}$ and $\sup_n ||h_n||_{\infty} < +\infty$ (it is important to note that $\|h\|_{\infty} \leq \liminf_{n \to \infty} ||h_n||_{\infty}$).

**Lemma 9** For any $t > 0$ and $1 < p \leq 2$, we have that $B^{t}_{p,p,\ell} \subset L^1(\mathbb{R}^3)$ (where $1/p + 1/q = 1$) and the immersion is continuous with respect to the pseudoconvergence in $B^{t}_{p,p,\ell}$. Furthermore $B^{t}_{p,p,\ell}$ is a Banach algebra.

**Proof** By Proposition 8 the interpolation space $(B^{0}_{\infty,\infty}, B^{t}_{p,p,\ell})_{\frac{1}{q},q}$ between $L^{\infty} \subset B^{0}_{\infty,\infty}$ and $B^{t}_{p,p,\ell}$ is exactly $B^{\frac{q}{q-q',r}=t}_{q,q',r}$, where $q = \frac{p}{4\pi}$. This means that $B^{t}_{p,p,\ell} \subset L^{\infty} \cap B^{t}_{p,p,\ell} \subset B^{0}_{\infty,\infty} \cap B^{s+2}_{p,p,\ell}$ is continuously embedded in $B^{t}_{q,q',r}(p-1)$. The fact that $B^{t}_{p,p,\ell}$ is an algebra is proven in Corollary 2.86 of [27].

We introduce the space $M^{s}_{p,p,\ell} \subset B^{t}_{p,p,\ell}$ with $s$ and $p$ as in Theorem 7 which is the set of Radon $\sigma$-finite measures $\mu$ contained in $B^{t}_{p,p,\ell}$ such that $|\mu| \in B^{t}_{p,p,\ell}$, where $|\mu| = \mu_{+} + \mu_{-}$, and where $\mu_{+}$ and $\mu_{-}$ are the unique positive measures such that $\mu = \mu_{+} - \mu_{-}$. We can define a notion of pseudoconvergence on $M^{s}_{p,p,\ell}$ in the following way: a sequence $\mu_n \in M^{s}_{p,p,\ell}$ pseudoconverges to $\mu \in M^{s}_{p,p,\ell}$ if $\mu_n$ converges strongly in $B^{t}_{p,p,\ell}$ and $\sup_n |||\mu_n|||_{B^{t}_{p,p,\ell}} < +\infty$.

We now consider the natural product $\cdot$ between smooth functions which are in $B^{s+2-\delta'}_{p,p,\ell}$ and smooth measures in $M^{s}_{p,p,\ell}$.

**Lemma 10** If $s, p$ satisfy the conditions of Theorem 7 and considering $\delta, \delta' > 0$ small enough, the product $\cdot$ can be extended in a unique and associative way from $B^{s+2-\delta'}_{p,p,\ell} \times M^{s}_{p,p,\ell}$ into $M^{s}_{p,p,\ell}$. This extension is (weakly) continuous with respect to the pseudoconvergence in $B^{s+2-\delta'}_{p,p,\ell}$ and $M^{s}_{p,p,\ell}$.

Furthermore for any $h \in B^{s+2-\delta'}_{p,p,\ell}$ and $\mu \in M^{s}_{p,p,\ell}$ we have

$$||h \cdot \mu||_{B^{s}_{p,p,\ell}} \leq ||h||_{\infty} \cdot ||\mu||_{B^{s}_{p,p,\ell}}.$$  \hspace{1cm} (42)

**Proof** First of all we note that the product $\cdot$ is well defined and (strongly) continuous as bilinear functional from $B^{s+2-\delta'}_{p,p,\ell}(p-1) \times B^{s}_{p,p,\ell}$ into $B^{s}_{p,p,\ell}$. Indeed this is a consequence of the fact that $(s + 2)(p - 1) + s = ps + 2(p - 1) = p(s + 2(1 - 1/p)) > 0$, if $s$ and $p$ satisfy the hypotheses of Theorem 7 and of Proposition 5.

The only thing that remains to be prove is inequality (42), since the other statements of the lemma easily follow from it. First of all, using the equivalent norm on Besov spaces of Proposition 5 we note that if $\mu$ is a Radon measure we have

$$|||\mu|||_{B^{s}_{p,p,\ell}} \sim \left(\int_{\mathbb{R}^s \times (0,1]} \left(\frac{|\mu|(B_{\lambda}(\hat{z}))}{\lambda^s}\right)^{p} \rho(\hat{z}) d\lambda d\hat{z}\right)^{1/p}.$$  \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} (43)

Using again Proposition 5 if $h$ is a continuous bounded function we have that

$$|||h \cdot \mu|||_{B^{s}_{p,p,\ell}} \sim \left(\int_{\mathbb{R}^s \times (0,1]} \left(\frac{|h \cdot \mu|(B_{\lambda}(\hat{z}))}{\lambda^s}\right)^{p} \rho(\hat{z}) d\lambda d\hat{z}\right)^{1/p} \lesssim ||h||_{\infty} \cdot ||\mu||_{B^{s}_{p,p,\ell}}.$$  \hspace{1cm} (44)
If $h$ is a generic function $B^{s+2-\delta'}_{p,p,\ell+\delta}$ there exists a sequence of smooth functions such that, as $n \to \infty$, $h_n \to h$ in $B^{s+2-\delta'}_{p,p,\ell+\delta}$ and $\|h_n\|_\infty \leq \|h\|_\infty$. By the first part of the lemma we have that $|h_n \cdot \mu|$ converges weakly in $S'((\mathbb{R}^d)$ to $|h \cdot \mu|$ from which we obtain
\[
\|h_n \cdot \mu\|_{B^{s,p,\ell}} \leq \liminf\|h_n \cdot \mu\|_{B^{s,p,\ell}} \leq \|\mu\|_{B^{s,p,\ell}} \liminf\|h_n\|_\infty \leq \|h\|_\infty \|\mu\|_{B^{s,p,\ell}}.
\]

We introduce the following map
\[
\mathcal{K}_g(\mu, \varphi) := -\alpha(-\Delta + m^2)^{-1}(g(z)G(\alpha \varphi(z)) \cdot \mu(z)),
\]
for any $|\alpha| < 4\sqrt{\pi}$, where $G : \mathbb{R} \to \mathbb{R}_+$ is an increasing smooth bounded function with all bounded derivatives such that $G(x) = \exp(x)$ for $x \leq 0$. It is clear that if $a \varphi \leq 0$ and if $\varphi$ solves equation (28) then we have
\[
\tilde{\varphi} = K_g(\eta, \tilde{\varphi}).
\]

**Lemma 11** For $p, s$ satisfying the hypotheses of Theorem 7 any $\mu \in M^s_{+,p,p,\ell}$ fixed and $\delta, \delta' > 0$ small enough, there exists at least a solution $\varphi \in B^{s+2-\delta'}_{p,p,\ell+\delta}$ to the equation
\[
\varphi = K_g(\mu, \varphi).
\]

**Proof** We want to use Schaefer’s fixed-point theorem (see Theorem 4 Section 9.2 Chapter 9 of [38]) to prove the lemma. In order to do this we have to prove that $K_g$ is continuous in $\varphi$, that it maps any bounded set into a compact set and that the set of solutions to the equations
\[
\varphi = \lambda K_g(\mu, \varphi)
\]
are bounded uniformly for all $0 < \lambda < 1$.

The continuity of $K_g$ (in both $\mu$ and $\varphi$) is a consequence of Lemma 10. Indeed in the cone $M^s_{+,p,p,\ell}$ the pseudoconvergence coincides with the convergence in $B^{\ast}_{p,p,\ell}$ since if $\mu \in M^s_{+,p,p,\ell}$ then $|\mu| = \mu$. Furthermore, the map $\varphi \to G(\varphi)$ is continuous (actually $C^1$) from $B^{\ast+2-\delta'}_{p,p,\ell+\delta}$ into $B^{s+2-\delta'}_{p,p,\ell+\delta}$. Finally the linear operator $(-\Delta + m^2)^{-1}$ is continuous from $B^{\ast}_{p,p,\ell}$ into $B^{\ast+2}_{p,p,\ell}$ and thus compact from $B^{\ast}_{p,p,\ell}$ into $B^{s+2-\delta'}_{p,p,\ell+\delta}$ (since, by Proposition 6 the immersion $B^{\ast+2}_{p,p,\ell+\delta} \hookrightarrow B^{s+2-\delta'}_{p,p,\ell+\delta}$ is compact). Thus by Lemma 10 the map $K_g$ is weakly continuous as a map into $B^{\ast+2}_{p,p,\ell}$ and strongly continuous as a map into $B^{s+2-\delta'}_{p,p,\ell+\delta}$.

The map $K_g$ is compact since the following inequality holds
\[
\|K_g(\mu, \varphi)\|_{B^{\ast+2}_{p,p,\ell}} \leq \|G\|_\infty \|\mu\|_{B^{\ast}_{p,p,\ell}}.
\]
and, by Proposition 6 we have the compact immersion $B^{\ast+2}_{p,p,\ell} \hookrightarrow B^{s+2-\delta'}_{p,p,\ell+\delta}$.

Finally the uniform boundedness in $\lambda$ follows from inequality (44). This proves the thesis of the lemma.

**Lemma 12** Under the hypotheses of Theorem 7 the solution to equation (43) is unique in $B^{s+2-\delta'}_{p,p,\ell+\delta}$ for $\delta, \delta' \geq 0$ small enough.

**Proof** Let $J : \mathbb{R} \to \mathbb{R}$ be a smooth, bounded, strictly increasing function such that $J(0) = 0$ and let $\tilde{\varphi}_1$ and $\tilde{\varphi}_2$ be two solutions to equation (43). By Lemma 9 $J(\tilde{\varphi}_1 - \tilde{\varphi}_2) \in B^{(s+2-\delta')_{p-1}}_{p,p,\ell+\delta}$ which implies that $\mu(x,J(\tilde{\varphi}_1 - \tilde{\varphi}_2)) \in (B^{\ast+2}_{p,p,\ell})^*$ for $\delta, \delta' \geq 0$ small enough, $\ell'$ large enough and any $\lambda > 0$. This means that
\[
\langle \mu^e(\lambda)J(\tilde{\varphi}_1 - \tilde{\varphi}_2), (-\Delta + m^2)(\tilde{\varphi}_1 - \tilde{\varphi}_2 - K_g(\mu, \tilde{\varphi}_1) + K_g(\mu, \tilde{\varphi}_2)) \rangle = 0.
\]
We are going to see that the inequality $\langle \rho \ell (\dot{\lambda} \zeta) J(\dot{\varphi}_1 - \varphi_2), (\Delta_\zeta + m^2)(\dot{\varphi}_1 - \varphi_2) \rangle \geq C \int \rho \ell (\dot{\lambda} \zeta) J(\dot{\varphi}_1 - \varphi_2) (\dot{\varphi}_1 - \varphi_2) d\zeta$ holds for $\lambda$ small enough and the same constant $C > 0$. Indeed let $f_1, f_2$ be two smooth functions then, for $\lambda$ small enough,

\[
\langle \rho \ell (\dot{\lambda} \zeta) J(f_1 - f_2), (\Delta_\zeta + m^2)(f_1 - f_2) \rangle = \int \rho \ell (\dot{\lambda} \zeta) J(f_1 - f_2)(\Delta_\zeta + m^2)(f_1 - f_2) d\zeta
\]

which holds only if $\varphi_1 - \varphi_2 = 0$ since $J$ is a strictly increasing function. $\Box$

**Remark 4** Combining Lemma 11 and Lemma 12 we deduce that the map $\mu \mapsto \varphi$, associating with the measure $\mu$ the unique solution $\varphi$ to equation (19), is continuous with respect to $\mu$. Indeed suppose that $\mu_n \rightarrow \mu$ in $\mathfrak{M}^{\ast}_{p,p,\ell}$ (and so in $B^{\ast}_{p,p,\ell}$), then by Lemma 10 we have that $\|\varphi_n\|_{B_{p,p,\ell}^{\ast}} \leq \sup \|\mu_n\|_{B_{p,p,\ell}^{\ast}}$, and so there exists a converging subsequence $\varphi_{n_k}$, as $n \rightarrow \infty$. On the other hand, since $K_g$ is continuous in both $\mu$ and $\varphi$, we get that $\varphi_{n_k}$ converges to the unique solution $\varphi$ to equation (19) associated with $\mu$. Since the limit does not depend on the subsequence we have that $\varphi_n \rightarrow \varphi$ strongly in $B_{p,p,\ell}^{\ast}$, which proves the continuity of the solution map.

This continuity of the solution map with respect to the measure $\mu$ is similar to the continuity result obtained for solutions of singular SPDEs defined by the methods of paraproduct calculus or regularity structure theory.

**Proof of Theorem 7** The existence and uniqueness of the solution to equation (28) are proved in Lemma 11 and Lemma 12 considering the equation $\phi = K(\eta, \phi)$. What remains to prove is the convergence of $\tilde{\phi}_{\varepsilon_n}$ to $\phi$, as $\varepsilon_n \rightarrow 0$. Let $\varepsilon_n \rightarrow 0$ be a sequence of positive numbers such that $\eta_{\varepsilon_n} \rightarrow \eta$ almost surely in $\mathfrak{M}^{\ast}_{p,p,\ell}$ and let $w \in W$ be such that $\eta_{\varepsilon_n}(w) \rightarrow \eta(w)$ in $\mathfrak{M}^{\ast}_{p,p,\ell}$, as $\varepsilon \rightarrow 0$. We note that

\[
\tilde{\phi}_{\varepsilon_n}(w) = \mathcal{A}^{\ast}_{p,p,\ell}(K_g(\eta_{\varepsilon_n}(w), \tilde{\phi}_{\varepsilon_n}(w))).
\]

From the equality (46) and Lemma 10 we obtain that

\[
\|\tilde{\phi}_{\varepsilon_n}(w)\|_{B_{p,p,\ell}^{\ast}} \leq \sup_{n \in \mathbb{N}} \|\eta_{\varepsilon_n}\|_{B_{p,p,\ell}^{\ast}}.
\]

26
uniformly in $n$. This means that there exists a subsequence $\bar{\phi}_{\varepsilon_n}(w)$ converging to some $\bar{\varphi}$ in $B_{p,p,\ell+\delta'}$. On the other hand we have that

$$\bar{\varphi} = \lim_{n \to +\infty} \bar{\phi}_{\varepsilon_n}(w) = \lim_{n \to +\infty} a_{n,2}^* \left( \mathbb{K}_g \left( \eta_{\varepsilon_n}(w), \bar{\phi}_{\varepsilon_n}(w) \right) \right) = \mathbb{K}_g(\eta(w), \varphi).$$

Since, by Lemma 12 equation (43) has a unique solution we have that all the subsequence $\bar{\phi}_{\varepsilon_n}(w)$ converge to the same $\bar{\varphi}$ and so $\bar{\varphi} = \hat{\varphi}(w)$ (which is the unique solution to equation (28) evaluated in $w \in W$). Since the previous reasoning holds for almost every $w \in W$ and since $\eta_{\varepsilon} \to \eta$ almost surely, we have that $\bar{\phi}_{\varepsilon} \to \hat{\phi}$ in $B_{p,p,\ell+\delta'}$ almost surely, as $\varepsilon \to 0$. 

\[ \square \]

### 3.3 Dimensional reduction

In this section we want to prove the reduction principle for equation (27), i.e. that the random field $\phi(0,z) = \mathbb{I}(0,z) + \phi(0,z)$ has the law $\kappa_0$ given by expression (20).

Before proving the dimensional reduction for equation (27) we have to prove that the restriction of a solution to a two dimensional hyperplane is a well defined operation.

**Lemma 13** There exists a version of the functional $x \mapsto \mathbb{I}(x,\cdot)$ which is continuous as a function from $\mathbb{R}^2$ into $C_0^0(\mathbb{R}^2) \subset B_{p,p,\ell+\delta'}^0$. Furthermore for any $h \in C_0^0(\mathbb{R}^2)$ the sequence of random variables $\int_{\mathbb{R}^2} a_s \ast (\mathbb{I}(x))(z)h(z)dz$ converges to $(\mathbb{I}(0,\cdot),h)$ in $L^2(d\mu)$, as $\varepsilon \to 0$.

**Proof** In order to prove that $x \mapsto \mathbb{I}(x,\cdot)$ admits a continuous version we prove that for any smooth function $h : \mathbb{R}^2 \to \mathbb{R}$ such that $(-\Delta_x + m^2)^{-1/2+}(h) \in L^2(\mathbb{R}^2)$, with $\varepsilon > 0$, we have

$$\mathbb{E}[\|\mathbb{I}(x,\cdot) - \mathbb{I}(y,\cdot),h)\|^2] \leq |x-y|^\varepsilon \|(-\Delta_x + m^2)^{-1/2+}(h)\|_{L^2(\mathbb{R}^2)},$$

where the constants implied by $\lesssim$ do not depend on $h,x,y$. This result, exploiting hypercontractivity and a version of Kolmogorov continuity criterion for multidimensional random fields, implies the continuity of $\mathbb{I}(x,\cdot)$ with respect to $x \in \mathbb{R}^2$. We note that, for any $x,y \in \mathbb{R}^2$:

$$\mathbb{E}[\|\mathbb{I}(x,\cdot) - \mathbb{I}(y,\cdot),h\|^2] = 2 \int_{\mathbb{R}^2} \frac{1 - e^{ik_1 \cdot (x-y)}}{(k_1^2 + k_2^2 + m^2)^{1+\varepsilon}} \frac{h(k_2)^2}{(k_1^2 + k_2^2 + m^2)^{1-\varepsilon}}dk_1dk_2.$$ 

Now we observe that $|1 - e^{ik_1 \cdot (x-y)}| \leq 2|x-y|^\varepsilon |k_1|^{1+\varepsilon}$ for any $p > 1$. If we choose $p = \frac{1}{1-\varepsilon}$, $0 < \varepsilon < 1$, we obtain the claim.

In order to prove that $\int_{\mathbb{R}^2} a_s \ast (\mathbb{I}(x))(z)h(z)dz$ converges, as $\varepsilon \to 0$, to $(\mathbb{I}(0,\cdot),h)$ in $L^2(d\mu)$, we note that the distribution $\mathbb{I}(\delta_0(x) \cdot h(z))$ belongs to $L^2(\mathbb{R}^2)$, implying that

$$\int_{\mathbb{R}^2} a_s \ast (\mathbb{I}(x))(z)h(z)dz = \delta[\mathbb{I}(\delta_0(x) \cdot a_s * h(z))] = \delta[\mathbb{I}(\delta_0(x) \cdot h(z))],$$

where $\delta$ denote the Skorohod integral with respect to the white noise $\xi$. Since $\mathbb{I}(\delta_0(x) \cdot a_s * h(z))$ converges to $\mathbb{I}(\delta_0(x) \cdot h(z))$ in $L^2(\mathbb{R}^2)$ also this claim follows. \[ \square \]

**Lemma 14** The operator $T_0 : C_0^0(\mathbb{R}^4) \to C_0^0(\mathbb{R}^4)$ given by $T_0(h)(\cdot) = h(0,\cdot)$ can be uniquely extended in a continuous way as an operator from $B_{p,p,\ell+4}^{s+2-\delta'}(\mathbb{R}^2)$ into $B_{p,p,\ell+4}^{s+2-\delta'-\delta'}(\mathbb{R}^2)$, when $s,p$ satisfies the hypotheses of Theorem 7 and $\delta' > 0$ is small enough.

**Proof** For the proof of this fact we refer to Section 4.4.1 and Section 4.4.2 of [68], see also Section 18.1 of [69]. 

\[ \square \]

**Theorem 8** Let $\phi$ be the unique solution to equation (27) then, if $|\alpha| < 4\sqrt{2}\pi$, there exists $\ell > 0$ such that for any measurable and bounded function $F$ on $B_{p,p,\ell+4}^0(\mathbb{R}^2)$ we have

$$\mathbb{E}[F(\phi(0,\cdot))] = \int_{B_{p,p,\ell+4}^0(\mathbb{R}^2)} F(\omega)d\kappa_0(\omega).$$

(47)
Proof We prove equation (47) for the case in which \( F(\omega) = \tilde{F}(\omega, f_1, \ldots, \omega, f_n) \) where \( \tilde{F} \) is a bounded continuous function, and \( f_1, \ldots, f_n \in C^\infty_0(\mathbb{R}^2) \). Since the functions of the previous form generate all the \( \sigma \)-algebra of Borel measurable functions on \( B_{p,p,\ell+\delta}^0 \), proving the theorem for functions of the previous form is equivalent to prove the theorem in general.

Since equation (52) holds, we have only to prove that \( \mathbb{E}[F(\phi_n(0,\cdot))] \to \mathbb{E}[F(\phi(0,\cdot))] \), as \( \epsilon_n \to 0 \) and where \( \epsilon_n \) is any subsequence such that \( \phi_{\epsilon_n} \to \tilde{\phi} \) almost surely (whose existence is proved in Theorem 7) and \( \int_{\cdot}^{\epsilon_n} F(\omega) d\kappa(\omega) \to \int_{\cdot}^{\epsilon_n} F(\omega) d\kappa(\omega) \), as \( \epsilon_n \to 0 \).

The first convergence follows from the fact that \( \phi_n = \phi_{\epsilon_n} + a_n(I\xi) \). Indeed, by Theorem 7 as \( \epsilon_n \to 0 \),

\[
\langle \phi_{\epsilon_n}(0,\cdot), f_i \rangle = \langle \phi_{\epsilon_n}, T_0^i(f_i) \rangle \to \langle \tilde{\phi}, T_0^i(f_i) \rangle = \langle \phi(0,\cdot), f_i \rangle,
\]

for any \( i = 1, \ldots, n \), almost surely and where the continuity of \( T_0^i \), proved in Lemma 13 is used. On the other hand, by Lemma 13 we have \( (a_n(I\xi)(0,\cdot), f_i) \to (I\xi(0,\cdot), f_i) \) in probability, as \( \epsilon_n \to 0 \), and this implies that \( \langle \phi_{\epsilon_n}(0,\cdot), f_i \rangle \to \langle \phi(0,\cdot), f_i \rangle \) in probability, for any \( i = 1, \ldots, n \).

Since the convergence in probability implies the one in distribution we get \( \mathbb{E}[F(\phi_n(0,\cdot))] \to \mathbb{E}[F(\phi(0,\cdot))] \). Finally since \( \kappa_{\epsilon_n} \) converges weakly to \( \kappa \), as \( \epsilon_n \to 0 \), the thesis follows.

Now we want to discuss what happens if we remove the cut-off \( g \) in equation (27) so we consider the equation

\[
(-\Delta + m^2)(\phi) + \alpha \exp(\alpha \phi - \infty) = \xi.
\]

In order to distinguish between the solution to equation (27) and equation (48) we denote by \( \phi_g \) the solution of the former and by \( \phi \) the solution of the latter. We use also the symbols \( \phi_g = \phi - I\xi \) and \( \phi = \phi - I\xi \).

Proposition 4 There exists an unique solution \( \phi \) to equation (48). Furthermore, for any affine transformation \( \Phi : \mathbb{R}^4 \to \mathbb{R}^4 \) in the Euclidean group of \( \mathbb{R}^4 \), the random field \( \Phi_\ast(\phi)(\hat{z}) = \phi(\Phi(\hat{z})) \) has the same law of \( \phi(\hat{z}) \).

Proof The existence and uniqueness for the solution to equation (48) can be proven as in Lemma 11 and Lemma 12 since the estimates used to prove those lemmas do not depend on \( g \).

The invariance of the law of the solutions with respect to affine transformations in the Euclidean group of \( \mathbb{R}^4 \) follows from the invariance (in law) of the white noise \( \xi \) and of the left-hand-side of equation (48) with respect to translations and rotations and from the uniqueness of the solution to equation (48).

Theorem 9 If \( g_n \) is an (increasing) sequence of cut-offs with compact support such that \( g_n \uparrow 1 \) then \( \phi_{g_n} \to \tilde{\phi} \) in \( B_{p,p,\ell+\delta}^0 \) (which means that \( \phi_{g_n} \to \tilde{\phi} \) in \( B_{p,p,\ell+\delta}^0(\mathbb{R}^4) \)). This means that the sequence of probability measures \( \kappa_{g_n} \) on \( B_{p,p,\ell+\delta}^0(\mathbb{R}^2) \) converges weakly, as \( n \to \infty \), to a probability measure \( \kappa \) which is invariant with respect to the natural action of the Euclidean group of \( \mathbb{R}^2 \) on \( B_{p,p,\ell+\delta}^0(\mathbb{R}^2) \) and does not depend on the sequence of cut-offs \( g_n \).

Proof The proof is essentially based on the fact that

\[
\|\tilde{\phi}\|_{B_{p,p,\ell+\delta}^0} \lesssim \|\eta\|_{B_{p,p,\ell}^0}
\]

uniformly on \( g \). From the previous inequality and some reasoning similar to the ones used in the proof of Theorem 7 the convergence follows. The properties of the limit measure \( \kappa \) follow from the same properties of the solution \( \phi \) to equation (48) proved in Proposition 4.
4 Elliptic quantization of the P(φ)\(_2\) model

In this section we discuss the elliptic stochastic quantization of the P(φ)\(_2\) model where P is a polynomial of even degree and satisfying Hypothesis QC. In order to avoid technical details we consider only the case P(φ) = \(\frac{\phi^2}{2n}\) for \(n \in \mathbb{N}\), the general case being then a straightforward generalisation. We consider the equation

\[ (-\Delta_x - \Delta_z + m^2)(\phi) + f(x)\phi^{2n-1} = \xi \quad (49)\]

where \(z \in M = \mathbb{T}^2\), \(0\) stands for the Wick product and \(\xi\) is a \(\mathbb{R}^2 \times \mathbb{T}^2\) white noise. Equation (49) can be better understood if we consider the equation for \(\tilde{\phi} := \phi - \mathcal{I}\xi\), the usual Da Prato-Debussche trick, obtaining the equation that is

\[ (-\Delta_x - \Delta_z + m^2)(\tilde{\phi}) + \sum_{k=0}^{2n-1} \binom{2n-1}{k} f(x) \cdot \mathcal{I}\xi^{\otimes k} \cdot \tilde{\phi}^{2n-1-k} = 0. \quad (50)\]

Equation (51) is expected to be well defined, since we expect that the solution \(\tilde{\phi}\) is in \(H^1(\mathbb{R}^2 \times \mathbb{T}^2) = W^{1,2}(\mathbb{R}^2 \times \mathbb{T}^2)\), in \(L^{2n}_{L^{2/n}}(\mathbb{R}^2 \times \mathbb{T}^2)\) (where \(L^{2n}_{L^{2/n}}\) is the weighted \(L^{2n}\) space with respect to the space weight \(f^{\frac{1}{n}}\)) and in \(B^{2+\delta}_{p,p,\ell}(\mathbb{R}^2 \times \mathbb{T}^2)\), where \(p = \frac{2n}{2n-1}\). Furthermore it is well known that \(\mathcal{I}\xi^{\otimes k} \in C^{\delta,\ell}_{\infty}(\mathbb{R}^2 \times \mathbb{T}^2)\) for any \(\ell > 0\) (see [46]). In general we expect that equation (50), and so equation (49), for any realization of the noise \(\xi\) admits multiple solutions. So we need a notion of weak solution to equation (50).

First of all we consider a fixed probability space \(\Omega = (\mathcal{C}^{-\delta}_{\ell}(\mathbb{R}^2 \times \mathbb{T}^2))^{2n} \times \mathfrak{M}\), where \(\mathfrak{M} = H^{1-\delta}_{\ell}(\mathbb{R}^2 \times \mathbb{T}^2) \cap L^{2n-\delta,\ell}_{L^{2/n}}(\mathbb{R}^2 \times \mathbb{T}^2) \cap B^{2-\delta}_{p,p,\ell}(\mathbb{R}^2 \times \mathbb{T}^2)\), and where \(\delta, \delta' > 0\) are small enough, that is the space where \((\mathcal{I}\xi, \mathcal{I}\xi^{\otimes 2}, \ldots, \mathcal{I}\xi^{\otimes 2n-1}) \in \Omega\) are defined.

**Definition 2** A probability measure \(\nu^e\) on \(\Omega\) is a weak solution to equation (50) if the projection of \(\nu^e\) on \(\mathcal{C}^{-\delta}_{\ell}(\mathbb{R}^2 \times \mathbb{T}^2)\) gives the law of \((\mathcal{I}\xi, \mathcal{I}\xi^{\otimes 2}, \ldots, \mathcal{I}\xi^{\otimes 2n-1})\) (which is the law of a Gaussian noise with covariance \((-\Delta_x - \Delta_z + m^2)^{-2}\) and its Wick powers) and it is supported on the set of solutions to the equation

\[ (-\Delta_x - \Delta_z + m^2)(\bar{\theta}) + \sum_{k=0}^{2n-1} \binom{2n-1}{k} f(x) \cdot \sigma_k \cdot \tilde{\bar{\theta}}^{2n-1-k} = 0, \quad (51)\]

where \(x \in \mathbb{R}^2\), \(z \in \mathbb{T}^2\), \((\sigma_1, \ldots, \sigma_{2n}, \bar{\theta}) \in \Omega\) and \(\sigma_0 = 1\), defined on \(\Omega^e\).

The weak solution \(\nu\) to equation (49) associated with the weak solution \(\nu^e\) to equation (50), is the probability law on \(\mathcal{C}^{-\delta}_{\ell}(\mathbb{R}^2 \times \mathbb{T}^2) + \mathfrak{M}\) given by the push-forward of \(\nu^e\) with respect to the map \(\sigma_1 + \theta\) defined on \(\Omega^e\).

We introduce a modified equation on \(\mathfrak{M}\) given by

\[ (-\Delta_x - \Delta_z + m^2)(\bar{\theta}) + a_{\varepsilon}^{2\ast} \sum_{k=0}^{2n-1} \binom{2n-1}{k} f(x) \cdot \sigma_k \cdot \tilde{\bar{\theta}}^{2n-1-k} = 0 \quad (52)\]

where \(a_{\varepsilon}\) is some regular enough mollifier on \(\mathbb{T}^2\) such that the operator \(\mathcal{A}_\varepsilon = a_{\varepsilon}^{\ast}\) satisfies Hypothesis HLA (for example we can take \(a_{\varepsilon}\) as the Green function associated with the operator \((-\varepsilon \Delta_x + 1)^{-k}\) for \(k\) large enough, \(\varepsilon > 0\).

**Lemma 15** Let \(\bar{\theta} \in \mathfrak{M}\) be a solution to equation (52) then \(\bar{\theta} \in H^1(\mathbb{R}^2 \times \mathbb{T}^2) \cap B^{2-\delta'}_{p,p,\ell}(\mathbb{R}^2 \times \mathbb{T}^2) \cap L^{2n}_{L^{2/n}}(\mathbb{R}^2 \times \mathbb{T}^2)\) (with \(\delta' < \delta\) as in the definition of \(\mathfrak{M}\)) and

\[ \|\bar{\theta}\|_{H^1} + \|\bar{\theta}\|_{L^{2n}_{L^{2/n}}} \lesssim \left( \sum_{k=1}^{2n} \|\sigma_k\|_{C^{-\delta}_\ell} \right)^{\frac{\gamma_1}{2}} \quad (53)\]

\[ \|\bar{\theta}\|_{B^{2-\delta'}_{p,p,\ell}} \lesssim \left( \|\theta\|_{H^1} + \|\theta\|_{L^{2n}} + \sum_{k=1}^{2n} \|\sigma_k\|_{C^{-\delta}_\ell} \right)^{\frac{\gamma_2}{2}} \quad (54)\]
where $\beta_1, \beta_2 \in \mathbb{R}_+$ and where $\beta_1, \beta_2$ and the constants implied by the symbol $\lesssim$ do not depend on $\epsilon$ and $\kappa$.

**Proof** Let $p > 1$, $0 < \gamma < 1$ and $\epsilon'' > 0$ be such that $\frac{1}{p} = \frac{\gamma}{2n-\delta'} + \frac{1-\gamma}{2}(1-\delta')$ and $\frac{2n-1}{p} + \epsilon'' = 1$. Then by Proposition 3 and Proposition 4, it is simple to see that $\bar{\theta} \in B_{p,2}^{(1-\gamma)(1-\delta')}((\mathbb{R}^2 \times T^2)$ and

$$\|\bar{\theta}\|_{B_{p,2}^{(1-\gamma)(1-\delta')}} \lesssim \|\bar{\theta}\|_{\mathcal{L}^{1-\gamma}} H_{1-\delta'}^{1-\delta'}.$$

This means that

$$\|(1 + |x|)^{\gamma} (A_{\prec}^{-\gamma} \bar{\theta})\|_{B_{p,p}^{2-\delta''}} \lesssim \left\| (1 + |x|)^{\gamma} \left( \sum_{k=0}^{2n-1} \left( \frac{2n}{k} \right)^k f(x) \cdot \sigma_k \cdot \bar{\theta}^{2n-k} \right) \right\|_{B_{p,p}^{2-\delta''}}$$

$$\lesssim \sum_{k=0}^{2n-1} \| (1 + |x|)^{\gamma} f(x) \cdot \sigma_k \cdot \bar{\theta}^{2n-k} \|_{B_{p,p}^{2-\delta''}}$$

$$\lesssim \sum_{k=0}^{2n-1} \left( (1 + |x|)^{\gamma} f(x) \cdot \sigma_k \cdot \bar{\theta}^{2n-k} \right) \cdot \sum_{k=0}^{2n-1} \| (1 + |x|)^{\gamma} f(x) \cdot \sigma_k \cdot \bar{\theta}^{2n-k} \|_{B_{p,p}^{2-\delta''}}$$

$$\lesssim \left[ \|\bar{\theta}\|_{H_{1-\delta'}^{1-\delta}} + \|\bar{\theta}\|_{\mathcal{L}^{1-\gamma}} H_{1-\delta'}^{1-\delta'} \right] \sum_{k=0}^{2n-1} \left( (1 + |x|)^{\gamma} f(x) \cdot \sigma_k \cdot \bar{\theta}^{2n-k} \right)$$

uniformly in $\epsilon$, this implies that $\bar{\theta} \in B_{p,p}^{2-\delta''}$ and also that $\bar{\theta} \in H^1$ since $\|\bar{\theta}\|_{H^1} \lesssim \|\bar{\theta} \cdot (-\Delta + m^2)\|_{L^1} \lesssim \|\bar{\theta}\|_{H_{1-\delta'}^{1-\delta}}$. Using the fact that $\bar{\theta} \in H^1$ and the previous reasoning we obtain inequality (54), as we shall now explain.

Let us multiply both sides equation (53) by $A_{\prec}^{-\gamma} \bar{\theta}$ (operation which is well defined since $\|(1 + |x|)^{\gamma} (A_{\prec}^{-\gamma} \bar{\theta})\|_{B_{p,p}^{2-\delta''}}$ is bounded) and take the integral over $\mathbb{R}^2 \times T^2$ obtaining

$$\|A_{\prec}^{-1} (\bar{\theta})\|_{H^1}^2 \leq -\|\bar{\theta}\|_{L_{f,j}^{2n-1}}^2 + C \sum_{k=0}^{2n-2} \| f^{1/2n-2}(2n-1) \|_{\mathcal{L}^{1-\gamma}} H_{1-\delta'}^{1-\delta'} \left( \|\bar{\theta}\|_{L_{f,j}^{2n-1}} \right)^{2n-k}$$

for some constant $C > 0$ depending only on $n$. Using that $\frac{2n-1}{p} + \epsilon'' = 1$, the fact that $\|\bar{\theta}\|_{H^1} \lesssim \|A_{\prec}^{-1} (\bar{\theta})\|_{H^1}^2$, $\|\bar{\theta}\|_{L_{f,j}^{2n-1}} \lesssim \|\bar{\theta}\|_{L_{f,j}^{2n-1}}$, and Young’s inequality for products we obtain

$$\|\bar{\theta}\|_{H^1}^2 + \|\bar{\theta}\|_{L_{f,j}^{2n-1}}^2 \lesssim \sum_{k=0}^{2n-2} \| f^{1/2n-2}(2n-1) \|_{\mathcal{L}^{1-\gamma}} \|\bar{\theta}\|_{L_{f,j}^{2n-1}}^{1/2}.$$ 

Inserting now inequality (54) into inequality (55) we obtain the thesis.

An easy consequence of the previous lemma is the following one.

**Lemma 16** Let $F : (C_{\epsilon}^{-\delta})^{2n-1} \to \mathcal{P}(\mathcal{W})$, $\epsilon > 0$, be the set-valued map associating $(\sigma_1, \ldots, \sigma_{2n-1})$ with the set of solutions to equation (53) in $\mathcal{W}$, if $K \subset (C_{\epsilon}^{-\delta})^{2n-1}$ is a compact set then $\bigcup_{\epsilon < 1} F(\epsilon)(K)$ is precompact in $\mathcal{W}$. 

30
There exists at least one weak solution to equation (50) that is tight. Then the thesis follows from Lemma 15.

Proof The proof of the lemma consists only in noticing that a consequence of Proposition 6 is that the inclusion map \( i : H^1(\mathbb{R}^2 \times \mathbb{T}^2) \cap B^0_{p,p}(\mathbb{R}^2 \times \mathbb{T}^2) \cap L_t^{2n}(\mathbb{R}^2 \times \mathbb{T}^2) \to \mathcal{W} \) is compact. Then the thesis follows from Lemma 15.

Hereafter we denote by \( \mathcal{P} : \mathcal{W} \to (C^\delta(\mathbb{R}^2 \times \mathbb{T}^2))^{2n} \) the natural projection of the Cartesian product \( \mathcal{W} = (C^\delta(\mathbb{R}^2 \times \mathbb{T}^2))^{2n} \times \mathcal{W} \) on the first component.

**Lemma 17** Let \( \nu_\varepsilon \) be a sequence of weak solutions to equation (52) and suppose that \( \Psi_+(\nu_\varepsilon) \) is tight. Then \( \nu_\varepsilon \) is tight. Furthermore suppose that \( \Psi_+(\nu_\varepsilon) \) weakly converges to the law of \( (I_\xi, I_\xi^2, \ldots, I_\xi^{c2n-1}) \) as \( \varepsilon \to 0 \), then any convergent subsequence \( \nu_{\varepsilon_n} \) converges, as \( \varepsilon_n \to 0 \), to a weak solution \( \nu^c \) to equation (50).

Proof The proof of the tightness of \( \nu_\varepsilon \) is similar to the one of Lemma 3, where Lemma 2 is replaced by Lemma 16.

Since \( \Psi_+(\nu_\varepsilon(\xi)) \) weakly converges to the law of \( (I_\xi, I_\xi^2, \ldots, I_\xi^{c2n-1}) \) and so \( \Psi_+(\nu^c) \) has the same law as \( (I_\xi, I_\xi^2, \ldots, I_\xi^{c2n-1}) \), the proof of the fact that \( \nu^c \) is a weak solution to equation (50) is equivalent to prove that \( \nu^c \) is such that for any \( C^1 \) bounded function \( F \) from \( B_{p,p}^c \) into \( \mathbb{R} \) with bounded derivative we have

\[
\int F \left( -\Delta_x + \Delta_z + m^2(\bar{\theta}) + \sum_{k=0}^{2n-1} \binom{2n-1}{k} f(x) \sigma_k \bar{\theta}^{2n-k} \right) d\nu^c = \int F(E) d\nu^c = F(0). \tag{57}
\]

We know that \( \int F(E_\varepsilon) d\nu_\varepsilon = F(0) \) with

\[
E_\varepsilon = (\Delta_x - \Delta_z + m^2(\bar{\theta}) + a^2 \sum_{k=0}^{2n-1} \binom{2n-1}{k} f(x) \sigma_k \bar{\theta}^{2n-k}).
\]

On the other hand \( E_\varepsilon \) converges to \( E \) uniformly on compact sets (since \( a^2 \sum_{k=0}^{2n-1} \binom{2n-1}{k} \) strongly converges as an operator to the identity on \( B_{p,p}(\mathbb{T}^2) \)), which implies that \( F \circ E_\varepsilon \) converges to \( F \circ E \) uniformly on compact sets, as \( \varepsilon \to 0 \).

This fact and the boundedness of \( F \) and of its derivatives implies (using a reasoning similar to the one of Lemma 3 see also Lemma 2 in [11]) that \( F \circ E_\varepsilon d\nu_\varepsilon \) weakly converges to \( F \circ E d\nu^c \), as \( \varepsilon \to 0 \). This implies equation (57) and thus the thesis of the lemma.

**Theorem 10** There exists at least one weak solution \( \nu^c \) to equation (50) such that, for any measurable bounded function \( F : B_{p,p}^c(\mathbb{T}^2) \to \mathbb{R} \) (where \( \delta > 0 \) and \( \ell > 0 \) as in the definition of \( \mathcal{W} \) and \( p = \frac{2m+1}{2m} \)),

\[
\int_{\mathcal{W}} F(\phi(0,\cdot)) \check{T}_f(\sigma, \bar{\theta}) d\nu^c(\sigma, \bar{\theta}) = Z_f \int_{B_{p,p}^c(\mathbb{T}^2)} F(\omega) d\kappa(\omega) \tag{58}
\]

where \( \phi = \sigma_1 + \bar{\theta} \) (where \( \sigma_1 \) and \( \bar{\theta} \) are as in Definition 3),

\[
\check{T}_f(\sigma, \bar{\theta}) = \exp \left( \sum_{k=0}^{2n} \binom{2n}{k} \langle \sigma_k \bar{\theta}^{2m-k}, f^k \rangle \right),
\]

\[
Z_f = \int_{\mathcal{W}} \check{T}_f(\sigma, \bar{\theta}) d\nu^c(\sigma, \bar{\theta})
\]

and \( \kappa \) is given by

\[
\frac{d\kappa}{d\mu^{-\Delta_z}} = \frac{\exp \left( \int_{\mathbb{T}^2} \omega^{2m} \frac{d\omega}{d\mu} \right)}{Z_\kappa},
\]

where \( \mu^{-\Delta_z} \) is the Gaussian with covariance given by (1) with \( \mathcal{L} = -\Delta_z \) and \( \mathcal{A} = \text{id} \).
Lemma 18 Let \( \nu_\epsilon^* \) be a sequence of weak solutions to equation (52) such that \( \Psi_*(\nu_\epsilon^*) \sim (a_*, \xi, \ldots, (a_*, \xi)^{n^2-1}) \) (where \( \sim \) means “with the same law”) then

\[
\int \exp \left( p \sum_{k=0}^{2n} \frac{2n}{k} \langle \sigma_k, f' \theta^{2n-k} \rangle \right) d\nu_\epsilon^* < C_p
\]

form some constant \( C_p \) uniform in \( \epsilon \) small enough and depending on \( p \geq 1 \).

Proof We want to use Nelson’s trick to prove the theorem (see Chapter V of [127]). Then we put

\[
E(\sigma_k, \theta) = \sum_{k=0}^{2n} \frac{2n}{k} \langle \sigma_k, f' \theta^{2n-k} \rangle
\]

and introduce the following expression

\[
E_{\epsilon,N}(\sigma_1, \theta) = \left\{ \begin{array}{ll}
\int_{\mathbb{R}^2 \times T^2} \sum_{k=0}^{2n} \left( \frac{2n}{k} \right) \left( a_{\frac{1}{2} - \epsilon} (\sigma_1) (\bar{z}) \right)^{\sigma_k} f'(x) \theta^{2n-k}(\bar{z}) d\bar{z}, & \text{for } \epsilon < \frac{1}{N}, \\
\int_{\mathbb{R}^2 \times T^2} \sum_{k=0}^{2n} \left( \frac{2n}{k} \right) \langle \sigma_1 (\bar{z}) \rangle^{\sigma_k} f'(x) \theta^{2n-k}(\bar{z}) d\bar{z}, & \text{for } \epsilon \geq \frac{1}{N}.
\end{array} \right.
\]

We have to prove that, for any \( p \geq 1 \),

\[
\left( \int |E - E_{\epsilon,N}|^p d\nu_\epsilon^* \right)^{1/p} \lesssim (p - 1)^u N^{-a} \tag{59}
\]

for some \( u \in \mathbb{N} \) and \( \alpha > 0 \) and

\[
E_{\epsilon,N} \lesssim -f'(x) (\log(N))^{\alpha'}, \tag{60}
\]

for some \( \alpha' > 0 \), and that both inequalities are uniform in \( \epsilon \). Inequality (59) is obvious when \( \epsilon < \frac{1}{N} \), since \( E - E_{\epsilon,N} = 0 \) \( \nu_\epsilon^* \)-almost surely. Consider the case \( \epsilon \geq \frac{1}{N} \) then

\[
|E - E_{\epsilon,N}| \lesssim \sum_{k=0}^{2n} \left\| \int_{\mathbb{R}^2 \times T^2} f'(x) \left( \sigma_k(z) - \left( a_{\frac{1}{2} - \epsilon} (\sigma_1) (\bar{z}) \right)^{\sigma_k} \right) \theta^{2n-k}(\bar{z}) d\bar{z} \right\|
\]

\[
\lesssim \sum_{k=1}^{2n} \left\| f'(x) \right\|_{2n-k} \left\| \sigma_k(z) - \left( a_{\frac{1}{2} - \epsilon} (\sigma_1) (\bar{z}) \right)^{\sigma_k} \right\|_{C^{-\delta}} \cdot \left\| f'(x) \right\|_{2n-k} \| \theta \|_{B^0_{p,p}}
\]

where \( p = \frac{2n-1}{2n} \). On the other hand, by Lemma 15 we have

\[
\left\| f'(x) \right\|_{2n-k} \| \theta \|_{B^0_{p,p}} \lesssim \left( \| \theta \|_{L^{2n}_{1/2,n} + H^1} \right)^{2n-k} \lesssim \left( \sum_{k=1}^{2n} \| \sigma_k \|_{C^{-\delta}} \right)^{\beta_1(2n-1)}
\]

\( \nu_\epsilon^* \)-almost surely and uniformly in \( \epsilon \). Using Holder’s inequality we obtain, for any \( p \geq 1 \),

\[
\left( \int |E - E_{\epsilon,N}|^p d\nu_\epsilon^* \right)^{\frac{1}{p}} \lesssim \sum_{k=1}^{2n} \left( \int \left\| f'(x) \right\|_{2n-k} \left\| \sigma_k(z) - \left( a_{\frac{1}{2} - \epsilon} (\sigma_1) (\bar{z}) \right)^{\sigma_k} \right\|_{C^{-\delta}}^{2\beta_1(2n-1)} d\nu_\epsilon^* \right)^{\frac{1}{p}}
\]

\[
\times \left( \int \left( \sum_{k=1}^{2n} \| \sigma_k \|_{C^{-\delta}} \right)^{2\beta_1(2n-1)p} d\nu_\epsilon^* \right)^{\frac{1}{p}}
\]

Since the law of \( \sigma_k \) is a multilinear functional of a Gaussian random field, by hypercontractivity we have that there exists \( m_1, m_2 \in \mathbb{N} \) and \( \alpha > 0 \) such that

\[
\int \left\| f'(x) \right\|_{2n-k} \left\| \sigma_k(z) - \left( a_{\frac{1}{2} - \epsilon} (\sigma_1) (\bar{z}) \right)^{\sigma_k} \right\|_{C^{-\delta}}^{2\beta_1(2n-1)p} d\nu_\epsilon^* \lesssim (p - 1)^{p\alpha_1} N^{-a}
\]

\[
\int \left( \sum_{k=1}^{2n} \| \sigma_k \|_{C^{-\delta}} \right)^{2\beta_1(2n-1)p} d\nu_\epsilon^* \lesssim (p - 1)^{p\alpha_2}
\]

32
uniformly in $\epsilon$. This prove inequality (59). We note that

$$\sum_{k=0}^{2n} \binom{2n}{k} \left( a_{\frac{N-\epsilon}{\epsilon}}(\sigma_1)(\tilde{z}) \right)^k f'(x) \tilde{\theta}^{2n-k}(\tilde{z}) = f'(x) H_{2n} \left( a_{\frac{N-\epsilon}{\epsilon}}(\sigma_1)(\tilde{z}) + \tilde{\theta}(\tilde{z}); c_{N,\epsilon} \right)$$

where $H_{2n}(x; \lambda)$ is the Hermite polynomial of degree $2n$ of a Gaussian random variable with variance $\lambda$ and $c_{N,\epsilon} = \mathbb{E} \left[ \left( a_{\frac{N}{\epsilon}}(\Xi) \right)^2 \right] \sim \log(N)$, as $N \to +\infty$ for any $\epsilon > 0$. It is simple to see that, for any $x \in \mathbb{R}^2$ and $\tilde{z} = (x, \tilde{z}) \in \mathbb{R}^2 \times \mathbb{T}^2$,

$$f'(x) H_{2n} \left( a_{\frac{N-\epsilon}{\epsilon}}(\sigma_1)(\tilde{z}) + \tilde{\theta}(\tilde{z}); c_{N,\epsilon} \right) \lesssim a_n f'(x) \left( a_{\frac{N-\epsilon}{\epsilon}}(\sigma_1)(\tilde{z}) + \tilde{\theta}(\tilde{z}) \right)^{2n}$$

$$+ f'(x) \sum_{k=1}^{m} a_k \left( a_{\frac{N-\epsilon}{\epsilon}}(\sigma_1)(\tilde{z}) + \tilde{\theta}(\tilde{z}) \right)^{2n-2k} c_{N,\epsilon}^{2k}$$

$$\lesssim a_n f'(x) \left( a_{\frac{N-\epsilon}{\epsilon}}(\sigma_1)(\tilde{z}) + \tilde{\theta}(\tilde{z}) \right)^{2n} - f'(x) c_{N,\epsilon}^n$$

$$\lesssim - f'(x) c_{N,\epsilon}^n \lesssim - f'(x)(\log(N))^n,$$

where we used that $f' < 0$ and $a_N, a'_N > 0$. This proves inequality (60).

Now we use Lemma V.5 of [67] and the fact that inequality (59) and (60) are uniform in $\epsilon$, to prove that there exist two constants $b, a'' > 0$ depending only on $f'$ and $m$ but not on $\epsilon > 0$ such that

$$\nu_\epsilon^b(E, \sigma, \hat{\theta}) > b \log(K) \leq e^{-K a''}.$$  

Inequality (61) implies that $\exp(E) \in \mathcal{L}^p(\nu_\epsilon^d)$ for any $p \geq 1$, and we have also a uniform bound on the $L^p$ norm of $\exp(E)$ with respect to $\epsilon > 0$. This concludes the proof of the lemma.

**Proof of Theorem 10** First we introduce the equation

$$(-\Delta_x - \Delta_z + m^2)(\phi) + a_\sigma^2 \ast (H_{2n}(\phi; c_\epsilon)) = a_\sigma \ast \xi,$$

(62) where $c_\epsilon = \mathbb{E}[(a_\sigma \ast \xi)^2]$. Equation (62) is of the form (11), and the potential $V_\epsilon(y) = H_{2n}(y; c_\epsilon)$, where $y \in \mathbb{R}$, satisfies Hypothesis QC since it is an even polynomial with positive leading coefficient. This means that, for any $\epsilon > 0$, there exists a weak solution $\nu_\epsilon$ to equation (62), such that

$$\int_{\mathbb{W}} F(\phi(0, \cdot)) Y_f(\phi) \nu_\epsilon = \int_{\mathbb{W}} F(\omega) \nu_\epsilon(\omega)$$

where $Y_f(\phi) = \int_{\mathbb{R}^2 \times \mathbb{T}^2} f'(x) H_{2n}(\phi(\tilde{z}); c_\epsilon) \tilde{z}$. On the other hand if by $\nu_\epsilon^\sigma$ we denote the law of $(a_\sigma \ast \xi_1, \ldots, (a_\sigma \ast \xi_1)^{2n}, \phi - a_\sigma \ast \xi_1)$ (where $\phi$ has law $\nu$ and $a_\sigma \ast \xi_1$ is given by equation (62)), we have that $\nu_\epsilon^\sigma$ is a solution to equation (62) and

$$\int_{\mathbb{W}} F(\phi(0, \cdot)) Y_f(\phi) \nu_\epsilon^\sigma = \int_{\mathbb{W}} F(\phi(0, \cdot)) \tilde{Y}_f(\sigma, \theta) \nu_\sigma^\epsilon(\sigma, \theta).$$

By Lemma 13 and Lemma 14 we have that the measure $F(\phi(0, \cdot)) \nu_\epsilon^\sigma$ weakly converges to $F(\phi(0, \cdot)) \nu_\epsilon^\sigma$, as $\epsilon \to 0$. Let $G_\epsilon : \mathcal{W}^r \to \mathbb{R}$, $r \in \mathbb{N}$, be a sequence of continuous functions such that $0 \leq G_\epsilon \leq 1$, $G_\epsilon = 1$ when $\tilde{Y}_f(\sigma, \theta) \leq r$ and $G_\epsilon = 0$ when $\tilde{Y}_f(\sigma, \theta) \geq 2r$ (the existence of this kind of functions follows from the fact that $\tilde{Y}_f(\sigma, \theta)$ is continuous on $\mathcal{W}^r$). Since $F(\phi(0, \cdot)) \nu_\epsilon^\sigma$ weakly converges to $F(\phi(0, \cdot)) \nu_\epsilon$, then $\int_{\mathbb{W}} G_\epsilon \tilde{Y}_f \nu_\epsilon \to \int_{\mathbb{W}} G_\epsilon \tilde{Y}_f \nu_\epsilon$, as $\epsilon \to 0$. On the other hand, by Lemma 18 for all $\epsilon > 0$ and any $r > 0$,

$$\left| \int_{\mathbb{W}} (G_\epsilon - 1) F \tilde{Y}_f \nu_\epsilon \right| \leq \int_{\tilde{Y}_f \geq r} |F| \tilde{Y}_f \nu_\epsilon \leq C_p \frac{\|F\|_{\mathcal{W}^p}}{r^{p-1}}$$

for any $p \geq 1$ (and a similar inequality is true for $\epsilon = 0$). Taking $r \to +\infty$ the thesis follows. \qed
A Besov spaces

In this appendix we recall some results on weighted Besov spaces used in this paper. We consider only the case of Besov spaces defined on \( \mathbb{R}^n \) but all what follows holds also for Besov spaces on \( \mathbb{T}^n \) or on \( \mathbb{R}^{n_1} \times \mathbb{T}^{n_2} \) (like the ones used in Section 4).

First we recall the definition of Littlewood-Paley block: let \( \chi, \varphi \) be smooth non-negative functions from \( \mathbb{R}^n \) into \( \mathbb{R} \) such that

- \( \text{supp}(\chi) \subset B_1(0) \) and \( \text{supp}(\varphi) \subset B_2(0) \setminus B_1(0) \)
- \( \chi, \varphi \leq 1 \) and \( \chi(y) + \sum_{j \geq 0} \varphi(2^{-j}y) = 1 \) for any \( y \in \mathbb{R}^n \)
- \( \text{supp}(\varphi(2^{-j} \cdot)) \cap \text{supp}(\varphi(2^{-i} \cdot)) = \emptyset \) if \( |i - j| > 1 \),

where by \( B_r(x) \) we denote the ball of center \( x \in \mathbb{R}^n \) and radius \( r > 0 \).

We introduce the following notations: \( \varphi_{-1} = \chi, \varphi_j(\cdot) = \varphi(2^{-j} \cdot), D_j = \hat{\varphi}_j \) and for any \( f \in \mathcal{S}(\mathbb{R}^n) \) we put \( \Delta_j(f) = D_j f \). Furthermore we write, for any \( \ell > 0 \), \( \rho_{\ell}(y) = (1 + |y|^2)^{-\ell/2} \), \( L_{\ell}^p(\mathbb{R}^d) \) is the \( L^p \) space with respect to the norm

\[
\|f\|_{L_{\ell}^p} = \left( \int_{\mathbb{R}^n} (f(y)\rho_{\ell}(y))^p dy \right)^{1/p},
\]

where \( p \in [1, +\infty] \).

**Definition 3** Consider \( s \in \mathbb{R}, p,q \in [1, +\infty] \) and \( \ell \geq 0 \). If \( f \in \mathcal{S}(\mathbb{R}^n) \) we define the norm

\[
\|f\|_{B_{p,q,\ell}^s} = \left( \sum_{j \geq -1} \|\Delta_j(f)\|_{L_{\ell}^p}^q \right)^{1/q}.
\]

The space \( B_{p,q,\ell}^s \) is the subset of \( \mathcal{S}'(\mathbb{R}^n) \) such that the norm \( (63) \) is finite.

**Remark 5** It is important to note that \( B_{2,2,\ell}^s \) is equal to the weighted Sobolev space \( W_{2,\ell}^{s,2} = H_{\ell}^s \) of \( L^2 \) distributions, and that for \( s > 0 \), \( s \notin \mathbb{N} \), \( B_{\infty,\infty}^s \) is equal to \( C^s \), the space of Hölder functions of regularity \( s \).

We denote by \( \mathfrak{F}_r \), with \( r \in \mathbb{N} \), the space of functions \( f \in C^r(\mathbb{R}^n) \) with support in \( B_1(0) \) and norm \( \|f\|_{C^r(\mathbb{R}^n)} \leq 1 \). If \( f \in \mathfrak{F}_r \) we write \( f_{\lambda,n}(\cdot) = \lambda^{-n} f \left( \frac{x}{\lambda^n} \right), y \in \mathbb{R}^n \) and \( \lambda > 0 \).

**Proposition 5** For any \( s \in \mathbb{R}, p,q \in [1, +\infty] \) and \( \ell \geq 0 \) an equivalent norm in the space \( B_{p,q,\ell}^s \) is given by the following expression

\[
\|f\|_{B_{p,q,\ell}^s} = \left( \int_0^1 \|\text{supp}_{\lambda \in \mathfrak{F}_r} |\langle f, g_{\lambda,n}\rangle|\|_{L_{\ell}^p}^q \right)^{1/q},
\]

where \( r \in \mathbb{N} \) is the first integer bigger than \( -s \).

**Proof** Theorem 6.15, in [70], proves the equivalence between norm \( (63) \) and the norm of \( B_{p,p,\ell}^s \) built using wavelets, while Proposition 2.4 in [49] proves the equivalence between the norm of \( B_{p,p,\ell}^s \) built using wavelets and the norm \( (64) \). Combining the two results we obtain the thesis. \( \square \)

**Proposition 6** Consider \( p_1, p_2, q_1, q_2 \in [1, \infty], \ell_1, \ell_2 \geq 0 \) and \( s_1, s_2 \in \mathbb{R} \) such that \( s_1 - \frac{n}{p_1} > s_2 - \frac{n}{p_2} \) and \( \ell_1 > \ell_2 \) then \( B_{p_2,q_2,\ell_2}^{s_2} \subset B_{p_1,q_1,\ell_1}^{s_1} \) and the immersion is compact.

Furthermore for \( 1 \leq p \leq 2 \)

\[
B_{p,p,\ell}^s \subset W_{p,p,\ell}^s \subset B_{p,2,\ell}^s;
\]

for \( 2 \leq p < \infty \)

\[
B_{p,2,\ell}^s \subset W_{p,p,\ell}^s \subset B_{p,p,\ell}^s
\]

and for \( p = \infty \) \( W_{p,\infty}^s \subset B_{\infty,\infty}^s \). Each of above immersions is continuous.
Consider the bilinear functional 

\[ \Pi : B^{s_1}_{p_1, q_1, \ell_1} \times B^{s_2}_{p_2, q_2, \ell_2} \to B^{\tilde{s}_3}_{p_3, q_3, \ell_3} \]

and we have, for any \( f, g \) for which the norms are defined:

\[ \| \Pi(f, g) \|_{B^{\tilde{s}_3}_{p_3, q_3, \ell_3}} \lesssim \| f \|_{B^{s_1}_{p_1, q_1, \ell_1}} \| g \|_{B^{s_2}_{p_2, q_2, \ell_2}}. \]

**Proof** The proof of the first part of the proposition can be found in Theorem 6.7 in [70].

The second part of the proposition is proved in Theorem 6.4.4 and Theorem 6.2.4 of [30] for unweighted spaces. The result for weighted spaces follows from the fact that \( f \in B^s_{p,q,\ell} \) and \( g \in W_{p,q}^{s,0} \) if and only if \( f \cdot \rho \in B^s_{p,q,\ell} \) and \( g \cdot \rho \in W_{p,q}^{s,0} \) (see [70] Theorem 6.5 point ii).

**Proposition 7** Consider \( p_1, p_2, p_3, q_1, q_2, q_3 \in [1, \infty] \) such that \( \frac{1}{p_1} + \frac{1}{p_2} = \frac{1}{p_3} \) and \( q_1 = q_3 \) and \( q_2 = \infty \), consider \( \ell_1, \ell_2, \ell_3 \geq 0 \) with \( \ell_1 + \ell_2 = \ell_3 \) and consider \( s_1 < 0 \) \( s_2 \geq 0 \) and \( s_3 = s_1 + s_2 \). Consider the bilinear functional \( \Pi(f, g) = f \cdot g \) defined on \( S(\mathbb{R}^n) \) taking values in \( S(\mathbb{R}^n) \). Then there exists a unique continuous extension of \( \Pi \) as the map

\[ \Pi : B^{s_1}_{p_1, q_1, \ell_1} \times B^{s_2}_{p_2, q_2, \ell_2} \to B^{s_3}_{p_3, q_3, \ell_3} \]

and we have, for any \( f, g \) for which the norms are defined:

\[ \| \Pi(f, g) \|_{B^{s_3}_{p_3, q_3, \ell_3}} \lesssim \| f \|_{B^{s_1}_{p_1, q_1, \ell_1}} \| g \|_{B^{s_2}_{p_2, q_2, \ell_2}}. \]

**Proof** The proof of the first part of the proposition can be found in Section 3.3 for Besov spaces with exponential weights. The proof for polynomial weights is similar.

**Proposition 8** Consider \( p_1, p_2, q_1, q_2 \in [1, \infty] \), \( \ell_1, \ell_2 \geq 0 \) and \( s_1, s_2 \in \mathbb{R} \). For any \( \theta \in [0, 1] \) we write \( \frac{\theta}{p_1} + \frac{1-\theta}{p_2} = \frac{1}{p_0}, \frac{\theta}{q_1} + \frac{1-\theta}{q_2} = \frac{1}{q_0}, \theta \ell_1 + (1-\theta)\ell_2 = \ell_0 \) and \( \theta s_1 + (1-\theta)s_2 = s_0 \). If \( f \in B^{s_1}_{p_1, q_1, \ell_1} \cap B^{s_2}_{p_2, q_2, \ell_2} \) then \( f \in B^{s_0}_{p_0, q_0, \ell_0} \), and furthermore

\[ \| f \|_{B^{s_0}_{p_0, q_0, \ell_0}} \leq \| f \|_{B^{s_1}_{p_1, q_1, \ell_1}} \| f \|_{B^{s_2}_{p_2, q_2, \ell_2}}. \]

Furthermore if \( f \in W^{s_1}_{p_1, p_1} \cap W^{s_2}_{p_2, p_2} \) then \( f \in W^{s_0}_{p_0, p_0} \), and furthermore

\[ \| f \|_{W^{s_0}_{p_0, p_0}} \leq \| f \|_{W^{s_1}_{p_1, p_1}} \| f \|_{W^{s_2}_{p_2, p_2}}. \]

**Proof** The proof is based on the fact that the complex interpolation \((B^{s_1}_{p_1, q_1, \ell_1}, B^{s_2}_{p_2, q_2, \ell_2})_{\theta}\) of the two spaces \(B^{s_1}_{p_1, q_1, \ell_1}, B^{s_2}_{p_2, q_2, \ell_2}\) is given by \(B^{s_0}_{p_0, q_0, \ell_0}\). This interpolation is proved in [30] Theorem 6.4.5 point (6) for unweighted space. For weighted space it follows from the fact that \( f \in B^{s_1}_{p_1, q_1, \ell_1}\), if and only if \( f \cdot \rho \in B^{s_1}_{p_1, q_1, \ell_1}\).

A similar reasoning, using the interpolation proved in [30] Theorem 6.4.5 point (7), holds also for the second inequality.
