Abstract

M2 isoform of pyruvate kinase (PKM2) plays an important role in reprogramming of cell metabolism which is a hallmark of tumorigenesis. PKM2 expression altering is closely related to cancer metabolism and tumor growth. In the present study, we analyzed the role of PKM2 expression in liver cancer in order to clarify its potential application value in the diagnosis and prognosis of liver cancer patients. In cancerous liver tissues, the PKM2 expression was significantly higher than normal tissues. High PKM2 expressing was related to patient’s age, gender, histological type, grade, stage, T classification and poor survival. Patients with Higher PKM2 expression had a shorter OS (P = 0.0013) and RFS (P = 0.027). ROC and Multivariate Cox analysis showed that high PKM2expression was a risk factor for patients’ poor prognosis. GSEA identified mitotic spindle, PI3K/Akt/mTOR signaling, notch signaling, apoptosis, G2M checkpoint and Wnt/β-Canetin signaling were enriched with high PKM2 expression phenotype. These findings suggested PKM2 expression has potential as a predictive biomarker for the diagnosis and prognosis of patients with liver cancer.

Introduction

Liver cancer, a clinically common malignant tumor with limited efficacy and poor prognosis, stills a main cause of global cancer-related deaths[1]. Despite tremendous progress in the diagnosis and treatment of liver cancer, the overall prognosis of patients is still unsatisfactory[2,3]. Therefore, it is extremely valuable and urgent to find more specific and reliable prognostic evaluation indicators of liver cancer.

Metabolic abnormalities are an important hallmark for tumorigenesis. Pyruvate-kinase (PKM) is the enzyme that catalyzes the final step in glycolysis, generating pyruvate and ATP from phosphoenolpyruvate and ADP[4]. This process consumes glucose, causing pyruvate to be converted to lactate[5]. In mammals, pyruvate kinase has four isoforms, including PKL, PKR, PKM1 and PKM2[6]. The PKL and PKR show tissue-specific expression in the liver tissue and red-blood cells, respectively[7]. They have different first exons and are defined by tissue-specific promoters[8]. The PKM consists of 12 exons, in which exons 9 and 10 are alternately spliced in mutually exclusive ways to produce PKM1 and PKM2 isoforms, respectively[9]. PKM2 is mainly expressed in a range of cancer cells, as well as in fetal and undifferentiated adult tissues, whereas PKM1 is predominantly expressed in terminally differentiated tissues[10]. Previous researches have shown that tissue-specific PKM1/L/R expression gradually diminishes and is replaced by PKM2 expression during tumorigenesis[11].

As a key regulator of aerobic glycolysis, the expression of PKM2 is essential for metabolic regulation[12]. In recent years, accumulating studies have shown that PKM2, in addition to its involvement in metabolic regulation, can also directly participate in gene transcription as a transcription coactivator and protein kinase, regulating the proliferation and apoptosis of undifferentiated cells[13–15]. PKM2 has also been found to have a potential prognostic role in the treatment of several cancers, including lung cancer[16], cervical cancer[17] and endometrial carcinoma[18–19]. This means that PKM2 may be used as a predictor in clinical diagnosis and prognosis evaluation of cancer patients.

In the present study, we investigated the relationship between the expression pattern of PKM2 in cancerous and non-cancerous liver tissues, as well as the association between high PKM2 expression and histological grade, stage, T/N/M classification, patient age, gender and survival status. The prognostic significance of PKM2
expression in liver cancer was also analyzed to clarify its potential application value in the treatment and prognosis of liver cancer patients.

**Materials And Methods**

**Data mining and preprocessing from The Cancer Genome Atlas (TCGA) database**

The RNAseq data of \( PKM2 \) (gene ID: 5315) and clinical information of liver hepatocellular carcinoma (LIHC) patient were obtained from The Cancer Genome Atlas (TCGA) database. The RNAseq value is estimated as \( \log_2(x + 1) \) converted RSEM normalized counts, and these data were processed using R software (version 4.0.1).

**Gene Set Enrichment Analysis**

To explore the distribution of predefined genomes and determine the potential mechanism to influence the effect of \( PKM2 \) expression on the prognosis of LIHC patients, we opted for GSEA (version 4.0.3). This analysis was performed through the "h.all.v7.2.symbols.gmt" gene set in the Molecular Signatures database. Gene-sets with a normal P value <0.05 was regarded as significantly enriched.

**Statistical Analysis**

R software package was used for statistical analysis. The ggplot2 package in R was performed for visualization. Chi-square test was used to evaluate the correlation between \( PKM2 \) expression and clinical characteristics of liver cancer. ROC analysis was used to evaluate the diagnostic significance of \( PKM2 \) expression. Kaplan-meier survival curve was used to analyze the correlation between \( PKM2 \) expression and patients OS and RFS. Univariate and multivariate Cox regression analysis were used to verify the correlation between \( PKM2 \) expression and survival rate and other clinical features. Statistical significance was defined as P <0.05.

**Results**

**The patients’ clinical characteristics and expression pattern of PKM2 in human liver cancer**

We obtained RNAseq of \( PKM2 \) expression and clinical information of 377 liver cancer patients from the TCGA database, including the patient age and gender; as well as histological type, histological grade, pathologic stage, T/N/M classification, radiation therapy, survival status and relapse (Table 1). Subsequently, we found that the expression of \( PKM2 \) in tumors was significantly higher than normal tissues (P < 0.0001, Fig. 1). Furthermore, \( PKM2 \) expression was also closely related to histological grade (P = 0.00011), histological stage (P = 0.00024), T classification (P < 0.0001), age (P = 0.0336), gender (P = 0.0136) and survival status (P = 0.00261).

**Diagnostic significance of PKM2 expression and relationship with clinical characteristics in human liver cancer**

To evaluate the role of \( PKM2 \) expression in diagnosis, ROC analysis was performed. We found that \( PKM2 \) expression had well diagnostic value (AUC = 0.744; Fig. 2A). In addition, we also analyzed the diagnostic value of \( PKM2 \) expression in different stages of the liver cancer, including AUC value of 0.698 in the first stage, 0.768 in the second stage, 0.786 in the third stage and 0.860 in the fourth stage (Fig. 2B-E). Subsequently, we analyzed the association between \( PKM2 \) expression and clinical features of liver cancer by divided patients into two groups (high or low \( PKM2 \) expression) according to median expression cutoff (Table 2). We found that high \( PKM2 \)
expression was related to patient age (P = 0.05), gender (P = 0.002), histological type (P = 0.041), histological grade (P = 0.003), pathologic stage (P = 0.001), T classification (P = 0.000) and poor survival (p = 0.020).

**Correlation of PKM2 Expression with OS in liver cancer patient**

We previously demonstrated the value of *PKM2* expression in the diagnosis of liver cancer. To further evaluate the correlation of *PKM2* expression with patient OS, Kaplan-Meier curves was performed. We found that high *PKM2* expression was able to shorten patient OS (P = 0.0013; Fig. 3). Subsequently, subgroup analysis also showed that high *PKM2* expression significantly affected the OS for patients with grade G1/G2 (P = 0.025), grade G3/G4 (P = 0.047) stage T1 (P = 0.0082), T3 (P = 0.045), N0 (P = 0.0097), M0 (P = 0.03), and M1/MX cancers (p = 0.012). Univariate and multivariate Cox analyses indicated that *PKM2* was a risk factor for poor OS (hazard ratio HR = 1.47, 95% confidence interval CI: 1.01–2.14, P = 0.047, Table 3). Interestingly, we found the high *PKM2* expression was a risk factor for poor OS in male patients (hazard ratio HR = 1.47, 95% confidence interval CI: 1.01–2.14, P = 0.047, Table 4), but not in female (P = 0.91; Table S1).

**Effect of PKM2 expression on RFS among liver cancer patients**

Next, we used Kaplan-Meier curves to explore the correlation of *PKM2* expression with patient RFS (Fig. 4). Survival analysis showed that high *PKM2* expression was associated with poor RFS (P = 0.027). Additionally, subgroup analysis also showed that high *PKM2* expression significantly affected the RFS for patients with N0/N1 (P = 0.039), and M0/M1 (P = 0.004). However, contrary to expectations, we did not observe that high *PKM2* expression is a risk factor for RFS by Univariate Cox analyses (Table S2). Unexpectedly, we found that high *PKM2* expression is not a risk factor for poor RFS in both male and female patients with LIHC (Table S2, 3).

**High PKM2 expression-related signaling pathway**

Identifying the activation of signaling pathways would facilitate a better understanding of molecular interactions, reactions and relationships, as well as disease process. To determine the signaling pathways activated in LIHC, we used GSEA to analyze the high and low *PKM2* expression datasets. The results showed that mitotic spindle, PI3K/Akt/mTOR signaling, notch signaling, apoptosis, G2M checkpoint and Wnt/β-Catenin signaling were enriched to the high *PKM2* expression phenotype (Table 5, Fig. 5).

**Discussion**

In the current study, we investigated the role of tumor *PKM2* expression as a predictor in cancerous and healthy liver tissues. This observation clearly shows that the *PKM2* level of tumors is significantly higher than healthy tissues, and elevating expression of *PKM2* is associated with histological grade, stage and vital status. In addition, univariate and multivariate COX analysis indicated that high *PKM2* expression was a predictor for decreased OS in the diagnosis and treatment of liver cancer patients.

Pyruvate Kinase Isotype M2 (*PKM2*) was a key enzyme involved in Warburg effect, and its activity was important for tumor metabolism and growth regulation. In most cancer cells, high *PKM2* expression was able to promote cancer cell proliferation and increase the degree of tumor malignancy. In addition, the necrosis and renewal of tumor cells can cause *PKM2* to be released into surrounding tissues, peripheral blood, feces of patients with gastrointestinal malignancies, and pleural effusion of patients with chest tumors, which can be used as
biomarkers to detect tumor metabolism and proliferation.\textsuperscript{25, 26} In early tumors, \( PKM2 \) expression showed heterogeneity, but the staining of metastatic tumor tissue was uniform and strong.\textsuperscript{27} This also indicated that \( PKM2 \) may play an important role in the occurrence and development of tumors. Previous studies had shown that the re-expression of \( PKM2 \) in tumor cells not only has important significance in regulating tumor cell sugar metabolism, but also gives tumor cells the advantage of selective growth.\textsuperscript{28} In this study, our results show that \( PKM2 \) expression also gradually increased as histologic grade increased from G1 to G4, as histologic stage increased from I to IV, and as T classification increased from T1 to T4. These results suggested that \( PKM2 \) expression was closely related with staging and grading of cancer, indicating that it can be used as a prognostic monitoring indicator in LIHC.

The phenotype of gene expression and genetic characteristics in tumors are related to signal activation occurrence and development of tumor. It had been reported that knockout of \( PKM2 \) in HCC cells inhibit cell proliferation and induce apoptosis in vivo and in vitro.\textsuperscript{29} In addition, \( PKM2 \) knockout was able to be used as a chemotherapeutic sensitizer of docetaxel in non-small cell lung cancer cells, resulting in cell viability inhibition, G2/M cell arrest and increased apoptosis.\textsuperscript{30} Moreover, \( PKM2 \) promotes cell migration and inhibits autophagy by mediating PI3K/AKT activation, and promotes the malignant development of gastric cancer.\textsuperscript{31} In fact, our results indicate that \( PKM2 \) expression is related to liver cancer progression and malignant tumors, and the implicit mechanism may be linked to mitotic spindle, PI3K/Akt/mTOR signaling, notch signaling, apoptosis, G2M checkpoint and Wnt/\( \beta \)-Catenin signaling as GSEA identified. These findings, combined with previous reports, greatly enrich our comprehension and understanding of the physiological role of \( PKM2 \) in tumor development and deterioration.

Recent studies have shown that the \( PKM2 \) expression was also a potential histopathological marker for the differential diagnosis of malignant and precancerous endometrial lesions, and high \( PKM2 \) expression in endometrial cancer is conducive to poor prognosis.\textsuperscript{32–34} C Papadaki et al. also indicated that \( PKM2 \) as a biomarker for chemosensitivity to front-line platinum-based chemotherapy in patients with metastatic non-small-cell lung cancer.\textsuperscript{35} In this study, we explored the correlation between high \( PKM2 \) expression and clinical diagnosis. In addition, high \( PKM2 \) expression reduces OS in patients. Interestingly, the high \( PKM2 \) expression was significantly correlated with OS in male patients (\( P = 0.00011 \)), but not in female (\( P = 0.91 \); Fig. 3). Additionally, although not significant at the 5\% level, high \( PKM2 \) expression is a risk factor for RFS in liver cancer male patients (\( P = 0.071 \); Fig. 4). Univariate and multivariate Cox analysis suggested that high \( PKM2 \) was an independent risk factor for poor OS in male patients, not in female patients with LIHC (Table 4 and S1). Thus, we speculate that \( PKM2 \) may be more suitable for male patients as a potential biomarker for diagnosis and prognosis in liver cancer.

In conclusion, we provided a reliable and comprehensive analysis of \( PKM2 \) expression patterns, diagnosis value and prognosis significance. It has possible to be a valuable potential prognostic biomarker and therapeutic target for liver cancer. It will give us a comprehensive understanding of the biological functions of \( PKM2 \) and provide new reference value through its regulated network of signaling pathway. This will help formulate a better supervision, diagnosis and treatment strategies for malignant tumor in clinical applications.

**Figures**
Figure 1

PKM2 expression pattern in human liver cancer. The expression of PKM2 was compared in cancerous and normal liver tissues; as well as in groups with different histological grade, histological stage, T classification, N classification, M classification, patient age, patient gender and survival status.
Figure 2

Diagnosis significance of PKM2 expression in liver cancer. (A) ROC curves of PKM2 expression were compared in cancerous liver tissues and normal liver tissues. (B-E) ROC curves of PKM2 expression in different stages of the liver cancer, including I, II, III, and IV.
Figure 3

Correlation of PKM2 expression with OS in liver cancer. Kaplan-Meier curves were used to evaluate the relationship between PKM2 expression and OS in all patients, as well as subgroup analysis (Female, Male, G1/G2, G3/G4, stage I/II, stage III/IV, T1-T4, N0, N1/NX, M0 and MX).
Figure 4

Effect of PKM2 expression on RFS among liver cancer patients. Kaplan-Meier curves of RFS of all liver cancer cases were compared, and sub-component analysis of different classifications (Female, Male, G1/G2, G3/G4, stage I/II, stage III/IV, T1-T4, N0, N1/NX, M0 and MX).
Figure 5

Gene-Set Enrichment plots. GSEA results showing differential enrichment of genes related to mitotic spindle, PI3K/Akt/mTOR signaling, notch signaling, apoptosis, G2M checkpoint and Wnt/β-Catenin signaling in LIHC cases with high PKM2 expression.
