The equivalent circuit for a regular capacitor can be represented by simulating the self-discharge behavior of supercapacitor from the concept of regular capacitor mechanisms and impedance of an R-C circuit, and constant phase elements (CPE), impedance of R-CPE, and fractional-order derivatives. The mathematical model was derived from each other to show their equality and relationships.

**Keywords:** Supercapacitor, Self-Discharge, CPE

### 1. Introduction

Self-discharge behavior is an important performance factor in supercapacitors. The term “self-discharge” is sometimes associated with the chemical (faradaic) reactions discharging the surface and excluding any physical processes which cause the voltage drop like charge redistribution [1]. Self-discharge rates are often higher in supercapacitors compared to batteries which makes self-discharge an important consideration in supercapacitors [2]. The practical supercapacitor electrodes, however suffer from a self-discharge at the charged state that is caused by leakage currents [3]. This paper discusses two dynamic mathematical models simulating the self-discharge behavior of supercapacitor from different concepts: (1) concept of regular capacitor mechanisms and impedance of an R-C circuit and (2) constant phase elements (CPE), impedance of R-CPE, and fractional-order derivatives.

### 2. Mathematical Background

#### 2.1. Capacitor Mechanism

The equivalent circuit for a regular capacitor can be modelled by representing a capacitor as capacitance C in parallel with resistance R [2].

![Fig. 1. Equivalent circuit of RC circuit](image)

The self-discharge of a regular capacitor can be computed as follows:

\[-C \frac{dv}{dt} = i = \frac{v}{R}\]  (1)

\[-C \frac{dv}{v} = \frac{dt}{R}\]  (2)

\[-\frac{dv}{v} = \frac{dt}{RC}\]  (3)

\[-\ln V = \frac{t}{RC} + \tau\]  (4)

when \(t = 0, V = V_i\)

\[\ln V = \tau\]  (5)

\[\ln \left(\frac{V_i}{V_0}\right) = \frac{t}{RC}\]  (6)

\[V_i/V_0 = \exp\left(-\frac{t}{RC}\right)\]  (7)

#### 2.2 Fractional Calculus

The fractional calculus (FC) is the generality of the traditional calculus that leads to similar concepts and tools, but with wider applicability. It allows the derivative and integral operations of arbitrary real or complex order, which makes it suitable for modeling ability.

The general format of fractional linear time-invariant (FLTI) systems equations is as follows:

\[f_n = \sum_{m=0}^{N} a_n D^{\alpha_n} y(t) = \sum_{m=0}^{M} b_m D^{\alpha_m} x(t)\]  (8)

where \(D\) means derivative and \(a_n\) \((n = 0, 1, 2,\ldots)\) are derivative orders that we will assume to be positive real numbers.

With the use of this definition, the Impulse Response and Transfer Function can be defined and compute. Same with other shift-invariant linear system the system described has the exponential as Eigen function. Letting \(x(t) = e^{\alpha}\), where
The mathematical expression of CPE from fractional capacitance and current is discussed and explained its behavior, the expression for mathematically.

\[ H(s) = s^\alpha \]  

(9)

Where \( s \in \mathbb{C} \) and \( t \in \mathbb{R} \), we obtain \( y(t) = H(s)e^{st} \), where \( H(s) \) is the transfer function given by

\[ Y(s) = \frac{V(s)}{I(s)} \]  

(15)

where \( I(s) \) is the electrical response (current) of the element on the applied potential \( V(s) \). Impedance can be expressed as a complex quantity when the possible phase shift between current and applied potential were considered.

In polar form

\[ Z(\omega) = |Z(\omega)|e^{i\phi} \]  

(16)

In rectangular form:

\[ Z(\omega) = Z_r(\omega) + iz^*(\omega) \]  

(17)

The impedance of an electric circuit containing an electrical resistance \( R \) and a capacitor \( C \), in the case of parallel connection is given by

\[ \frac{1}{Z} = \frac{1}{R} + i\omega C \]  

(18)

2.3. Constant Phase Element (CPE)

CPE is a phenomenological term used by Burg in 1984. It is an empirical impedance that its phase angle is independent of frequency. CPE is often related to dispersion attributed to surface inhomogeneities and distributed time constants and obeys Kramers-Kronig relations provided that \( |\alpha| \leq 1 \).

In electrical engineering, CPE behavior is explained as the frequency dispersion of capacitance by dielectric relaxation, where the electric current density follows the change of an electric field with a delay [11]. Fractional calculus was used to express the phenomenon mathematically. In [12], the model of leaky capacitor was discussed and explained its behavior, the expression for capacitance and current is

\[ \ell(t) = C \frac{d^\alpha u(t)}{dt^\alpha}, \quad 0<\alpha<1 \]  

(13)

where \( d^\alpha u(t)/dt^\alpha \) was used as the “fractional-order derivative.”

The mathematical expression of CPE from fractional derivative and in frequency domain was represented as

\[ Z_{\text{CPE}} = Qs^{-\alpha} \]  

(14)

The coefficient \( Q \) and the fractional exponent \( \alpha \) are the parameters of CPE, generally \(-1 < \alpha < 1\) [11-15].

2.4 Impedance as a Function of Frequency

Impedance of an electrical element is defined as a function of frequency

\[ Z(\omega) = \frac{V(\omega)}{I(\omega)} \]  

(15)

where \( I(\omega) \) is the electrical response (current) of the element on the applied potential \( V(\omega) \). Impedance can be expressed as a complex quantity when the possible phase shift between current and applied potential were considered.

In polar form

\[ Z(\omega) = |Z(\omega)|e^{i\phi} \]  

(16)

In rectangular form:

\[ Z(\omega) = Z_r(\omega) + iz^*(\omega) \]  

(17)

The impedance of an electric circuit containing an electrical resistance \( R \) and a capacitor \( C \), in the case of parallel connection is given by

\[ \frac{1}{Z} = \frac{1}{R} + i\omega C \]  

(18)

2.3. Constant Phase Element (CPE)

CPE is a phenomenological term used by Burg in 1984. It is an empirical impedance that its phase angle is independent of frequency. CPE is often related to dispersion attributed to surface inhomogeneities and distributed time constants and obeys Kramers-Kronig relations provided that \( |\alpha| \leq 1 \).

In electrical engineering, CPE behavior is explained as the frequency dispersion of capacitance by dielectric relaxation, where the electric current density follows the change of an electric field with a delay [11]. Fractional calculus was used to express the phenomenon mathematically. In [12], the model of leaky capacitor was discussed and explained its behavior, the expression for capacitance and current is

\[ \ell(t) = C \frac{d^\alpha u(t)}{dt^\alpha}, \quad 0<\alpha<1 \]  

(13)

where \( d^\alpha u(t)/dt^\alpha \) was used as the “fractional-order derivative.”

The mathematical expression of CPE from fractional derivative and in frequency domain was represented as

\[ Z_{\text{CPE}} = Qs^{-\alpha} \]  

(14)

The coefficient \( Q \) and the fractional exponent \( \alpha \) are the parameters of CPE, generally \(-1 < \alpha < 1\) [11-15].

2.4 Impedance as a Function of Frequency

Impedance of an electrical element is defined as a function of frequency

\[ Z(\omega) = \frac{V(\omega)}{I(\omega)} \]  

(15)

where \( I(\omega) \) is the electrical response (current) of the element on the applied potential \( V(\omega) \). Impedance can be expressed as a complex quantity when the possible phase shift between current and applied potential were considered.

In polar form

\[ Z(\omega) = |Z(\omega)|e^{i\phi} \]  

(16)

In rectangular form:

\[ Z(\omega) = Z_r(\omega) + iz^*(\omega) \]  

(17)

The impedance of an electric circuit containing an electrical resistance \( R \) and a capacitor \( C \), in the case of parallel connection is given by

\[ \frac{1}{Z} = \frac{1}{R} + i\omega C \]  

(18)

2.3. Constant Phase Element (CPE)

CPE is a phenomenological term used by Burg in 1984. It is an empirical impedance that its phase angle is independent of frequency. CPE is often related to dispersion attributed to surface inhomogeneities and distributed time constants and obeys Kramers-Kronig relations provided that \( |\alpha| \leq 1 \).

In electrical engineering, CPE behavior is explained as the frequency dispersion of capacitance by dielectric relaxation, where the electric current density follows the change of an electric field with a delay [11]. Fractional calculus was used to express the phenomenon mathematically. In [12], the model of leaky capacitor was discussed and explained its behavior, the expression for capacitance and current is

\[ \ell(t) = C \frac{d^\alpha u(t)}{dt^\alpha}, \quad 0<\alpha<1 \]  

(13)

where \( d^\alpha u(t)/dt^\alpha \) was used as the “fractional-order derivative.”

The mathematical expression of CPE from fractional derivative and in frequency domain was represented as

\[ Z_{\text{CPE}} = Qs^{-\alpha} \]  

(14)

The coefficient \( Q \) and the fractional exponent \( \alpha \) are the parameters of CPE, generally \(-1 < \alpha < 1\) [11-15].

2.4 Impedance as a Function of Frequency

Impedance of an electrical element is defined as a function of frequency

\[ Z(\omega) = \frac{V(\omega)}{I(\omega)} \]  

(15)

where \( I(\omega) \) is the electrical response (current) of the element on the applied potential \( V(\omega) \). Impedance can be expressed as a complex quantity when the possible phase shift between current and applied potential were considered.

In polar form

\[ Z(\omega) = |Z(\omega)|e^{i\phi} \]  

(16)

In rectangular form:

\[ Z(\omega) = Z_r(\omega) + iz^*(\omega) \]  

(17)

The impedance of an electric circuit containing an electrical resistance \( R \) and a capacitor \( C \), in the case of parallel connection is given by

\[ \frac{1}{Z} = \frac{1}{R} + i\omega C \]  

(18)

2.3. Constant Phase Element (CPE)

CPE is a phenomenological term used by Burg in 1984. It is an empirical impedance that its phase angle is independent of frequency. CPE is often related to dispersion attributed to surface inhomogeneities and distributed time constants and obeys Kramers-Kronig relations provided that \( |\alpha| \leq 1 \).

In electrical engineering, CPE behavior is explained as the frequency dispersion of capacitance by dielectric relaxation, where the electric current density follows the change of an electric field with a delay [11]. Fractional calculus was used to express the phenomenon mathematically. In [12], the model of leaky capacitor was discussed and explained its behavior, the expression for capacitance and current is

\[ \ell(t) = C \frac{d^\alpha u(t)}{dt^\alpha}, \quad 0<\alpha<1 \]  

(13)

where \( d^\alpha u(t)/dt^\alpha \) was used as the “fractional-order derivative.”

The mathematical expression of CPE from fractional derivative and in frequency domain was represented as

\[ Z_{\text{CPE}} = Qs^{-\alpha} \]  

(14)
from the self-discharge characteristics of regular capacitors. The second model is from the concept of CPE and fractional-order derivatives.

In the first mathematical model the self-discharge is in exponential form. The voltage across the terminal of the supercapacitor is:

\[ V_c(t) = V_R(t) + V_e(t) \]  

(20)

and the terminal voltage of the supercapacitor in discharging is,

\[ V_e(t) = V_c(t) - V_R(t) \]  

(21)

The voltage \( V(t) \) can be determined from the equation of parallel RC circuit (see Fig. 1), subject to the initial condition that \( V(0) = V_0 \), the \( V_c(t) \) of can be calculated and expressed as

\[ V_c(t) = V_0 \exp \left( -\frac{t}{R_pC_{TOTAL}} \right) \]  

(22)

and

\[ V(t) = V_c(t) + V_{ESR}(t) \]  

(23)

so that,

\[ V(t) = V_0 \left( 1 + \frac{ESR}{R_p} \right) \exp \left( -\frac{t}{R_pC_{TOTAL}} \right) \]  

(24)

Converting the equation into self-discharge and adding exponent “n” to the time constant 1/RC to consider a fractional capacitor.

\[ V_{SC}(t)/V_o = \exp \left( -\left( t - t_0/R_pC \right)^n \right) \]  

(25)

\[ V_{SC}(t) = V_o \left( 1 + \frac{ESR}{R_p} \right) \exp \left( -\left( t - t_0/R_pC \right)^n \right) \]  

(26)

Since \( 1 + \frac{ESR}{R_p} \) is almost equal to 1, the simplified mathematical equation is

\[ V_{SC}(t) = V_o \exp \left( -\left( t - t_0/R_pC \right)^n \right) \]  

(27)

In last equation above, \( V_{SC}(t) \) is the voltage during self-discharge, \( V_0 \) is the maximum voltage after charge, \( t \) is the time of self-discharge, \( t_0 \) is the charging time, \( R_p \) is the leakage resistance, and \( C \) is the maximum capacitance.

To compute for value of \( n \)

\[ \ln(V_c/V_{SC}) = \exp(t/R_pC)^{-n} \]  

(28)

\[ 1 - n = \frac{\ln(\ln(V_c/V_{SC}))}{\ln(t/R_pC)} \]  

(29)

where \( V_c \) is the maximum charged voltage, \( V_{SC} \) is the self-discharge voltage, \( t \) is the time of self-discharge \( R_p \) is the leakage resistance, and \( C \) is the rated capacitance.

In second mathematical model, fractional-order derivative was used to convert an impedance formula in frequency domain for R-CPE circuit.

The formula to compute the total impedance is

\[ Z = ioL + R_s + \sqrt{\frac{R_p}{(io)^nC}} \cdot \coth \left( \frac{(io)^nR_pC}{2} \right) \]  

(30)

and when \( \omega \) is equal to infinity

\[ Z \approx \sqrt{\frac{R_p}{(io)^nC}} \quad (\omega \rightarrow \infty) \]  

(31)

but when \( \omega \) is equal to zero

\[ Z \approx R_s + R_e + \frac{1}{(io)^nC} \quad (\omega \rightarrow 0) \]  

(32)

CPE can be computed as

\[ Z_{CPE} = \frac{1}{(io)^nC} \]  

(33)

and

\[ \alpha = 1 - \gamma \]  

(34)

Using fractional order and laplace transform in solving for the order of the system \( \alpha \).

\[ Z(S) = \frac{1}{CS^{(1-\gamma)}} \]  

(35)

\[ L^{-1}Z(S) = \frac{1}{C}L^{-1}\left( \frac{1}{s^{\alpha}} \right) \]  

(36)

The time domain of \( Z_{CPE} \) is now

\[ Z(t) = \frac{1}{C} \left( t^{1-\gamma} \right) \]  

(37)

Transforming the formula from impedance to voltage

\[ V(t) = I_c \times \left( R_s + R_e + \frac{1}{C^{\alpha}(2-\gamma)} \right) \]  

(38)

\[ V(t) = I_c \times \left( R_s + R_e + \frac{\left( t - t_{cut-off} \right)^{1-\gamma}}{C^{\alpha}(2-\gamma)} \right) - I_c \times \left( R_s + R_e + \frac{(t-2t_{cut-off})^{1-\gamma}}{C^{\alpha}(2-\gamma)} \right) \]  

(39)

where ESR and \( V_o \)

\[ ESR = R_s + R_e \]  

(40)

\[ V_o = I_c \times ESR \]  

(41)

and the equation for charging and self-discharge are

\[ V(t) = V_o + I_c \frac{1}{C} \left( t^{1-\gamma} \right) \]  

- charging \( (2-\gamma)! \)  

(42)

\[ V(t) = V_o + I_c \left( \frac{1}{C} \left( t^{1-\gamma} - (t - t_{cut-off})^{1-\gamma} \right) \right) \]  

- self-discharge \( (2-\gamma)! \)  

(43)

where \( V(t) \) is the voltage self-discharge, \( V_o \) is the initial voltage before self-discharge, \( I_c \) is the charging current, \( t \) as the self-discharge time and \( C \) is the rated capacitance.

4. Derivation of self-discharge mathematical model

The concept of complex number conversion from rectangular to polar form can be applied in both potential and impedance to prove their equality.

\[ Z = |Z(\omega)| \cdot e^{i\theta} \]  

(polar form)
The two mathematical models of self-discharge is almost equal to each other,

\[ V_{SC}(t) = V_o + I_C \left( \frac{e^{-t}}{\omega (2\pi)^k} \right) = V_{SC}(t) = V_o \times \exp \left[-\left( t - t_o/R_p C \right)^n \right] \]

equation in the left side is in rectangular form while equation at the right side is in polar form.

First, consider equation at the left side where

\[ V_o = I_C \times ESR \tag{44} \]

while

\[ \left( \frac{e^{-t}}{\omega (2\pi)^k} \right) = Z(t) \tag{45} \]

so

\[ V_{SC}(t) = V_o + V(t) \tag{46} \]

\( V_o \) is the real part of the potential while \( V(t) \) is the imaginary part of the potential.

Then, consider equation at the right side where \( V_o \) is the magnitude and

\[ \exp \left[-\left( t - t_o/R_p C \right)^n \right] \tag{47} \]

is the angle in polar form.

However, \( \gamma \) is almost equal to \( n \), where \( \gamma \) came from \( \alpha \) (CPE) with equation

\[ \alpha = 1 - \gamma \tag{48} \]

and to prove the relationship between \( n \) and \( \alpha \), we can use the parallel R-CPE and RC circuit and plot.

The real and imaginary part of impedance can be written as

\[ Z = \frac{1}{R} + i\omega, C \tag{51} \]

In Fig. 3 where \( n = 1 \), the real part of impedance equal to its imaginary part and produce an equation of

\[ C = \frac{1}{\omega p} \tag{52} \]

so

\[ \omega_p = \frac{1}{R_C} \tag{53} \]

while in R-CPE

\[ \omega_p = \frac{1}{(RQ)^{1/n}} \tag{54} \]

Assuming that \( \omega_p \) and \( \omega'_p \) for both parallel R-CPE and R-C circuits (fig. n) are equivalent

\[ \frac{1}{R_C} = \frac{1}{(RQ)^{1/n}} \tag{55} \]

To calculate ‘real’ capacity \( C \):

\[ C = R \frac{1+n}{\pi}, Q \frac{1}{\pi} \tag{56} \]

\[ Q \frac{1}{\pi} = \frac{C}{R \frac{1}{\pi}} \tag{57} \]

Raised both sides by \( n \) :

\[ Q = \frac{C^n}{R^{1-n}} \tag{58} \]

\[ Q = C^n R^n R^{-1} \tag{59} \]

\[ \frac{1}{Z_{CPE}} = \frac{(RQ)^n (i\omega)^n}{R} \tag{60} \]

and if the last equation above \( Z_{CPE} \) can be computed using a real capacity \( C \) and resistance where \( n \) is equal to \( \alpha \).

5. Mathematical Model vs. Actual Simulation

Three commercially available supercapacitors were used in the actual simulation using 580 Battery Test System and Bplot software. Both supercapacitors were charge with constant current of 1 mA and held in constant voltage of 2.5V for two hours.

| Component                  | A   | B   | C   |
|----------------------------|-----|-----|-----|
| Rated Capacitance (F)      | 3.3 | 4.7 | 10  |
| Rated Voltage (V)          | 2.5 | 2.5 | 2.5 |
| Temperature Range (°C)     | -25 to 60 | -26 to 60 | -40 to 70 |
The first mathematical model was used to compare with the actual simulation done in potentiostat since both model and experiment is in time domain. The mathematical model is in good agreement with the actual simulation results as seen in Fig. 4, Fig. 5 and Fig. 6. Table II shows the computed and extracted parameters from the mathematical model and actual simulation.

| Component | A     | B     | C     |
|-----------|-------|-------|-------|
| n         | 0.208 | 0.215 | 0.215 |
| ESR (Ω)   | 2.028 x10^{-03} | 3.168 x10^{-04} | 4.000 x10^{-02} |
| Leakage Current (A) | 6.692 x10^{-06} | 4.467 x10^{-06} | 3.125 x10^{-02} |
