Abstract: In this study, Al–Y$_2$O$_3$ nanocomposites were synthesized via mechanical alloying and microwave-assisted sintering. The effect of different levels of yttrium oxide on the microstructural and mechanical properties of the Al–Y$_2$O$_3$ nanocomposites were investigated. The density of the Al–Y$_2$O$_3$ nanocomposites increased with increasing Y$_2$O$_3$ volume fraction in the aluminum matrix, while the porosity decreased. Scanning electron microscopy analysis of the nanocomposites showed the homogeneous distribution of the Y$_2$O$_3$ nanoparticles in the aluminum matrix. X-ray diffraction analysis revealed the presence of yttria particles in the Al matrix. The mechanical properties of the Al–Y$_2$O$_3$ nanocomposites increased as the addition of yttria reached to 1.5 vol. % and thereafter decreased. The microhardness first increased from 38 Hv to 81 Hv, and then decreased to 74 ± 4 Hv for 1.5 vol. % yttria. The Al–1.5 vol. % Y$_2$O$_3$ nanocomposite exhibited the best ultimate compressive strength and yielded a strength of 359 ± 7 and 111 ± 5 MPa, respectively. The Al–Y$_2$O$_3$ nanocomposites showed higher hardness, yield strength, and compressive strength than the microwave-assisted mechanically alloyed pure Al.

Keywords: aluminum; yttrium oxide (yttria); mechanical alloying; microwave sintering; microstructure and mechanical properties

1. Introduction

Metal matrix composites (MMCs) find noteworthy applications in many engineering sectors due to their superior properties such as high strength, high-temperature capability, specific modulus, and good wear resistance compared to monolithic base materials. The mechanical performances of MMCs often show greater improvement than can be achieved by conventional strengthening methods in monolithic alloys [1–4].

Aluminum (Al)-based metal matrix composites (AMMCs) are an excellent choice for automotive, aerospace, defense, and nuclear power sectors because of their lightweight and favorable mechanical, thermal, and physical properties. Aluminum (Al)-based metal matrix composites are capable of achieving high strength, high-fatigue resistance, high-wear and corrosion resistance, and good compatibility with various manufacturing processes [5–8].

At present, ceramic particle-reinforced Al-matrix nanocomposites have been prepared primarily by mechanical alloying, forging, and casting routes [9–11]. Among these methods, mechanical alloying (MA) has been widely used to fabricate Al-matrix nanocomposites due its cost-effectiveness, simplicity,
and its ability to improve the properties vis-a-vis those of the unreinforced matrix [12,13]. There are many sintering techniques such as conventional, spark plasma, vacuum, and microwave sintering processes [14–17]. Among these techniques, the microwave sintering process is a heating method that offers the ability to balance the radiant and microwave heating effects. In this process, heat is generated within the sample by rapid oscillation of dipoles at microwave frequencies. Microwave sintering provides efficient internal heating, and energy is supplied directly to the material. Therefore, this process avoids the significant temperature gradient between the surface and interior. Microwave sintering is a high-technology heating process that can save both energy and time [18].

In AMMCs, the most common types of reinforcement that can be used are SiC, Si₃N₄, Y₂O₃, TiC, and Al₂O₃ [19–23]. Among these ceramics, Y₂O₃ was selected as the reinforcement to be used in this study due to its high strength, hardness, melting point, and thermal conductivity [24–26]. Yttria is an air-stable particle, white in color and solid in substance. By adding the yttria to the aluminum, the strength, corrosion resistance, and wear properties are improved [27]. Yttria is well sintered to a high density and low coefficient of thermal expansion, and has excellent strength properties [28,29]. According to the authors’ knowledge, there are no reports in the literature on Al–Y₂O₃ nanocomposites processed by mechanical alloying and microwave sintering.

Therefore, in this current research, Al–Y₂O₃ nanocomposites were prepared by mechanical alloying and microwave heating, and the effect of Y₂O₃ addition on the microstructure and mechanical performance of Al–Y₂O₃ nanocomposites were investigated.

2. Materials and Methods

Pure Al (99.5% purity, with an average particle size of 10 µm) and Y₂O₃ nanoparticles (99.99% purity, with an average particle size of 50–70 nm) were purchased from Alfa Aesar (Tewksbury, MA, USA) and selected as raw materials for the synthesis of Al–Y₂O₃ nanocomposites.

Aluminum–yttria composites were prepared with 0, 0.5, 1.0, 1.5, and 2.0 vol. % yttria nanoparticle contents. The mixture of powders was blended at room temperature using a Planetary Ball Mill (PM 200) for 2 h, with a rotation speed of 200 rpm. No balls were used during the blending of powders. The mixed powder (~1.0 gm) was compacted into cylindrical pellets by applying a pressure of 50 MPa with a holding time of 1 min. The compacted cylindrical pellets were sintered in a microwave sintering furnace at a temperature of 550 °C with a heating rate of 10 °C/min and providing a dwell time of 30 min. The microwave furnace had an alumina insulation and silicon carbide susceptor. The silicon carbide susceptor was used to increase the heating rate and hybrid heating. Alumina insulation prevents heat loss and is used as well to protect the interior walls of the microwave oven. The compacted pellets were placed at the center of the cavity and sintering was conducted at the multimode cavity [30]. Figure 1 shows the schematic representation of the microwave sintering furnace.

The density of the sintered samples was calculated using Archimedes’ principle. The porosity of the samples was calculated by the theoretical and experimental density of the composite samples. The X-ray diffraction (XRD, PANalytical X’pert Pro, PANalytical B.V., Almelo, The Netherlands) analysis was performed to identify the phases present in Al–Y₂O₃ nanocomposites. The XRD patterns were recorded in the 2θ range of 20–90° with a step size of 0.02° and a scanning rate of 1.5°/min. The microstructural characterization and determination of the distribution of the yttria nanoparticles in the aluminum matrix were carried out using scanning electron microscopy (SEM, JeolNeoscope JSM6000, Tokyo, Japan) and energy dispersive X-ray spectroscopy (EDS, Tokyo, Japan).

The microhardness of the Al–Y₂O₃ nanocomposites was determined using Vickers microhardness tester (MKV-h21, USA). Microhardness analysis was carried out to investigate the effect of yttria on the hardness of the Al–Y₂O₃ nanocomposite, carrying the load of 25 gf and a dwell time of 10 s, for each sample with an average of five successive indentations. Compressive strength analysis was performed at room temperature using a universal testing machine (Lloyd), under an engineering strain rate of 10⁻⁴/s.
The respective data of each sample were obtained by an average of three successive values of test results. From the load–displacement curves, 0.2% offset compressive yield strength (CYS), ultimate compressive strength (UCS), and compressive strain were determined.

3. Results and Discussion

3.1. Density and Porosity of Al–Y$_2$O$_3$ Nanocomposites

Density and porosity values of the microwave sintered Al–Y$_2$O$_3$ nanocomposites with different contents of yttria in the Al matrix are shown in Table 1.

| Composition         | Theoretical Density (g/cc) | Experimental Density (g/cc) | Porosity (%) |
|---------------------|-----------------------------|----------------------------|--------------|
| Pure Al             | 2.700                       | 2.679 ± 0.005              | 0.78         |
| Al–0.5 vol. % Y$_2$O$_3$ | 2.712                       | 2.701 ± 0.004              | 0.41         |
| Al–1.0 vol. % Y$_2$O$_3$ | 2.723                       | 2.741 ± 0.007              | 0.33         |
| Al–1.5 vol. % Y$_2$O$_3$ | 2.735                       | 2.728 ± 0.006              | 0.26         |
| Al–2.0 vol. % Y$_2$O$_3$ | 2.746                       | 2.741 ± 0.008              | 0.18         |

It can be observed that the density of the composite gradually increased with the increase of the yttria content since the density of yttria (5.01 g/cc) is higher than that of Al (2.70 g/cc). Generally, the higher relative density of sintered samples influences the mechanical properties of the composites. The porosity of the composites decreased by increasing the amount of yttria content. The decrease in porosity with increasing yttria content shows that the presence of the hard yttria particles did not impair the densification of the Al powder [31]. Microwave heating was one of the main reasons for the low porosity of the synthesized composites.

3.2. XRD Analysis of Al–Y$_2$O$_3$ Nanocomposites

The X-ray diffraction (XRD) patterns of the microwave sintered pure Al and Al–Y$_2$O$_3$ nanocomposites with different amounts of Y$_2$O$_3$ are shown in Figure 2a. Figure 2b shows the enlarged patterns of the Al–1.5 vol. % Y$_2$O$_3$ nanocomposite. The XRD patterns clearly indicate the presence of Y$_2$O$_3$ nanoparticles in the Al composite matrix. Due to the small volume of yttria reinforcement present in these composites, the yttria peaks were very small compared to the aluminum matrix peaks. Also, it can be seen that the intensity of the yttria diffraction peaks increased with the increasing of yttria percentage. The XRD results show that the main elements of Al (higher peak) and Y$_2$O$_3$ (lower peak) are present in Al–Y$_2$O$_3$ nanocomposites.
3.3. SEM Analysis of Al–Y₂O₃ Nanocomposites

The SEM and EDS images of the microwave sintered Al–Y₂O₃ nanocomposites with different contents of yttria are shown in Figure 3. The results of microstructural characterization revealed that yttria particulates were present individually and in relatively smaller clusters indicating an improvement in their distribution. The EDS analysis confirms the aluminum and yttria particles present in the Al matrix. The EDS mapping spectrum of all nanocomposites were mainly composed of Al, Y, and O elements, as shown in Figure 3b,d,f. The microcracks were restricted by the presence of hard and homogeneous yttria particles in the Al-matrix and influenced the microstructure and mechanical properties of Al–Y₂O₃ nanocomposites. The specimen with 2 vol. % of yttria particles shows the decreasing of the interparticle distances as the concentration of the nanoparticles increased.

3.4. Microhardness of Al–Y₂O₃ Nanocomposites

Vickers microhardness was measured on all specimens to study the effect of Y₂O₃ content on the microhardness. Figure 4 shows the results of the microhardness of the Al–Y₂O₃ nanocomposites with different content of yttria. From the Table 2, the microhardness of the composite increased as the yttria increased of up to 1.5 vol. % and then decreased at 2.0 vol. % Y₂O₃. The considerable increase in hardness could be attributed to the presence of homogeneously distributed hard ceramic nanoparticles and dispersion hardening effect [34]. Al–2.0 vol. % Y₂O₃ nanocomposites show a decreased microhardness value, which was mainly due to the agglomeration of the yttria and increasing presence of clustering of yttria in the case of the Al matrix [35]. The microhardness of the microwave sintered samples in this study was found to be higher than the vacuum sintering and arc-melting samples [36].

The increment of microhardness in the composite materials was due to the presence of hard ceramic particles.

Table 2. Microhardness, yield strength, and ultimate compressive strength of Al–Y₂O₃ nanocomposites.

| Composition       | Microhardness (Hv) | YS (MPa) | UCS (MPa) | Compression Strain (%) |
|-------------------|--------------------|----------|-----------|------------------------|
| Pure Al           | 38 ± 3             | 69 ± 2   | 318 ± 5   | >60                    |
| Al–0.5 vol. % Y₂O₃| 46 ± 4             | 71 ± 4   | 329 ± 6   | >60                    |
| Al–1.0 vol. % Y₂O₃| 63 ± 2             | 87 ± 3   | 337 ± 3   | >60                    |
| Al–1.5 vol. % Y₂O₃| 81 ± 3             | 126 ± 5  | 374 ± 6   | >60                    |
| Al–2.0 vol. % Y₂O₃| 74 ± 5             | 111 ± 5  | 359 ± 7   | >60                    |

Figure 4. Microhardness of Al–Y$_2$O$_3$ nanocomposites.
3.5. Compressive Analysis of Al–Y$_2$O$_3$ Nanocomposites

The compressive test was conducted on the microwave sintered pure Al and Al–Y$_2$O$_3$ nanocomposites and strengths were compared. Figure 5a shows the engineering stress–strain curves of the Al–Y$_2$O$_3$ nanocomposites with different content of yttria. Figure 5b shows the corresponding mechanical data of Al–Y$_2$O$_3$ nanocomposites.

![Figure 5. (a) The compressive stress–strain curves and (b) strength (yield and ultimate) of the Al–Y$_2$O$_3$ nanocomposites.](image)

The yield strength and ultimate compressive strength of Al–Y$_2$O$_3$ nanocomposites show increased values up to 1.5 vol. % of yttria then decreased as shown in Table 2. Al–1.5 vol. %Y$_2$O$_3$ nanocomposites show the maximum yield strength (YS) of 126 ± 5 MPa and ultimate compressive strength (UCS) of 374 ± 6 MPa at a uniform strain of ~60%. These results show the improvement of mechanical properties of Al–Y$_2$O$_3$ nanocomposites compared to the pure Al. The increased mechanical properties of the Al–Y$_2$O$_3$ nanocomposites are attributed to the dispersion hardening effect and homogeneous distribution of hard reinforcements in the Al-matrix [37]. Al–2.0 vol. % Y$_2$O$_3$ nanocomposites show a decreased microhardness value, mainly due to the agglomeration of nanoparticles and grain growth [38]. Reinforcement amounts, density, heating mechanisms factors also govern the variation of the mechanical properties. However, compression properties of the microwave sintered Al–1.5 vol. % Y$_2$O$_3$ nanocomposites are interestingly superior to those of other reinforced AMMCs [39–43].

There are several strengthening mechanisms to enhance materials’ mechanical properties like hardness and compressive strength of the composite materials. The strengthening of the composites is not only dependent on unique strengthening mechanisms, but it also depends on several strengthening mechanisms.

In the present study, the strengthening mechanism of the Al–Y$_2$O$_3$ nanocomposites mainly depended on dispersion hardening due to the hard yttria particles present in the aluminum matrix. The increase in strength and hardness may be attributable to Orowan strengthening [44,45].

3.6. Fractography of Al–Y$_2$O$_3$ Nanocomposites

Figure 6 shows the fracture surface images of microwave sintered pure Al and Al–Y$_2$O$_3$ nanocomposites under compressive loading. The SEM observations in nanocomposites show typical shear mode fractures and cracks obtained at a 45° to the fracture surfaces with respect to the compressive loading axis. It can be observed that the compressive deformations obtained in pure aluminum and aluminum composites with yttria are different, due to the work hardening behavior. The plastic deformations are restricted by the presence of the second phase in Al–Y$_2$O$_3$ nanocomposites [46].
4. Conclusions

The Al–Y₂O₃ nanocomposites were successfully synthesized by mechanical alloying and microwave sintering method. The influence of yttria nanoparticles on the microstructure and mechanical properties of the Al–Y₂O₃ nanocomposites were investigated in detail. The density of the composites increased with the increasing of yttria content while porosity decreased. The SEM analysis showed the homogeneous distribution of yttria particles in aluminum composites. The Al–Y₂O₃ nanocomposites exhibited better mechanical properties compared to pure Al. The optimum hardness (81 ± 3 Hv), yield strength (126 ± 5 MPa), and ultimate compression strength (374 ± 6 MPa) and compressive strain (~60%) values were obtained for the Al–1.5 vol. % Y₂O₃ nanocomposite. This significant enhancement in mechanical properties in Al–1.5 vol. % Y₂O₃ nanocomposites make them potential candidates for automotive applications.
