ABSTRACT: Mollusc assemblages of the Orava reservoir, the biggest dam reservoir in Slovakia, were studied in 2020. The reservoir, built in 1941–1953, is situated in north-western Slovakia. Sixteen aquatic mollusc species (13 gastropods, 3 bivalves) were recorded. Valvata piscinalis (O. F. Müller), Radix auricularia (Linnaeus) and Gyraulus parvus (Say) were the most frequent; they were recorded in more than ten sites each. Rich mollusc assemblages, composed mainly of gastropods, were found in sites with rich littoral vegetation of macrophytes. The bivalve diversity and abundance were very small, especially compared to the other studied dam reservoirs. The current results were compared with the previous surveys. The occurrence of Radix lagotis (Schrank) is its first reliable record in Slovakia. Viviparus acerosus (Bourguignat), Aplexa hypnorum (Linnaeus), Anodonta cygnea (Linnaeus), non-native Potamopyrgus antipodarum (Gray) and Physa acuta (Draparnaud) were recorded in this area for the first time and their sites are outside their known range in Slovakia.

KEY WORDS: Mollusca; dam reservoir; mollusc assemblages; Orava; Radix lagotis

INTRODUCTION

Dams have been altering river ecosystems since humans started constructing them. The earliest dams were built 5,000 years ago (Petts & Gurnell 2005). Their primary function was to create perennial sources of water for irrigation. Water retention in dam reservoirs induces physical, chemical and biological changes, which also lead to changes in animal communities. Mollusc assemblages of selected dam reservoirs in the Czech Republic and Slovakia were studied in the last decades (e.g. Dvořák & Beran 2004, Beran & Dvořák 2006, Beran 2007, 2020).

The Orava dam reservoir, with an area of 35.2 km², is the biggest in Slovakia and has existed for almost 70 years. Its mollusc assemblages were studied in the past. In 1990 Šteffek (1991) analysed the sediments near the dam after emptying of the reservoir; his publication included also the results of several earlier visits in 1982, 1986 and 1989. He found 11 species and three species of pea mussels, found also in 1990 and mentioned later in Šteffek & Nagel (2004). Lucijanská (1991) studied the sediments in the reservoir in 1990 and found 12 species. The lack of data on the current composition of the mollusc assemblages, the fact that the previous surveys were mostly based on the contents of sediments and also the possibility to compare changes in the assemblages during more than 30 years were the main reasons for a more detailed survey of 2020. The results of this survey are presented here.
MATERIAL AND METHODS

STUDY AREA

The Orava dam reservoir is situated in north-western Slovakia near the boundary with Poland at an altitude of 601 m a.s.l. and is the largest dam reservoir in Slovakia (35.2 km²). It was created by the construction of a dam between 1941 and 1953 on the former two sources of the Orava River. The average depth of the reservoir is 15 metres. Extensive wetlands are situated around it, especially along the northern shore of the reservoir.

SAMPLING AND MATERIAL PROCESSING

The survey was done in 2020. In total, 12 sites were sampled (Fig. 1, Appendix 1). The main sampling method was washing vegetation and sediments on a metal sieve (diameter 20 cm, 0.8 mm mesh) combined with collecting by hand from the surface of stones, wood and artificial materials (e.g. plastic bags and bottles) and with snorkelling in shallow parts (to the depth of ca. 3 m). Collecting in each site lasted for about 45 minutes (excluding snorkelling). Based on the number of recorded specimens, the molluscs were divided into three categories of abundance (for explanation see Table 1).

Species were identified based on shell characters. When necessary, identification was based on the structure of copulatory organs. Specimens for dissection were killed in hot water and then fixed in 80% ethanol. Selected material of shells and alcohol-preserved specimens is deposited in the author’s collection. Selected material of Radix lagotis (Schrank, 1803) was dissected and identified by Katrin Schniebs (Dresden, Germany). Otherwise classification used follows Horská et al. (2020).

RESULTS

In total, 16 species of aquatic molluscs (13 gastropods, 3 bivalves) were recorded at 12 sites of the Orava dam reservoir (Fig. 1). The assemblages documented at particular sites consisted of 5–9 species. A list of molluscs found at particular sites and estimation of their abundance are shown in Table 1. Only

Table 1. List of aquatic molluscs recorded in the Orava dam reservoir: x – few specimens, xx – scattered occurrence, xxx – abundant occurrence

Fig. 2. Northern shore with the littoral zone overgrown by macrophytes and with extensive wetlands (site No. 8). Photo: LUBOŠ BERAN
Valvata piscinalis, Radix auricularia and Gyraulus parvus were found in more than 10 sites each, *Potamopyrgus antipodarum, Stagnicola turricula, Radix lagotis, Physa acuta* and *Gyraulus crista* were recorded in 5–10 sites each, while the number of sites for the remaining species ranged from one to four.

Rich assemblages composed mainly of gastropods were found at sites with littoral zone overgrown by macrophytes (sites No. 3, 5–9, 11–12, Fig. 2) while sites with sparse macrophyte vegetation were inhabited by fewer species (e.g., sites No. 1–2, 4, 10, Fig. 3). The diversity and abundance of bivalves were very small. Only three species were found at one or two sites each and always as few specimens.

Due to the existence of historical data (Lučivjanská 1991, Šteffek 1991, Šteffek & Nagel 2004), the present results could be compared with the earlier surveys (Table 2).

Abundant populations of *Viviparus acerosus* which is listed as Vulnerable in the Red List of molluscs of Slovakia (Šteffek & Vavrová 2006) were found at three sites and this record is outside its known range in Slovakia. *R. lagotis* was found in seven sites. It is the first reliable record of this species in Slovakia.

The native *Aplexa hypnorum, Anodonta cygnea* and the non-native *Potamopyrgus antipodarum* and *Physa acuta* were found in this area for the first time and their sites are outside the known range in Slovakia (Horsák et al. 2020).

### Table 2. List of aquatic molluscs recorded at different periods: 1982–1990 (Lučivjanská 1991, Šteffek 1991, Šteffek & Nagel 2004); 2020 – this study

| *Pisidium obtusale* (Lamarck, 1818) |          |      |

Number of species: 16
DISCUSSION

The Orava dam reservoir provides appropriate habitats for abundant populations of species, which prefer standing waters; it differs from natural habitats of the area, such as nutrient-poor small rivers, brooks, springs, or small wetlands. Although it is situated at higher altitude, the reservoir is inhabited by richer mollusc assemblages and by many species, which are more common in lowlands. A similar situation is observed, for example, in the Lipno dam reservoir (48.7 km²) in the Czech Republic which is situated in the altitude of 725 m a.s.l. The Vltava River upstream of the reservoir is inhabited by poor assemblages, which are typical of nutrient-poor waters, while the reservoir harbours rich mollusc assemblages composed of 26 species; for many of them the Lipno reservoir is the highest-situated site of occurrence in the Czech Republic (Beran & Dvořák 2006).

The small abundance and poor diversity of bivalves in the Orava reservoir are surprising. While abundant populations of six species (5 unionids) were found in 2020 in the second biggest dam reservoir in Slovakia, Zemplínská Šírava (Beran 2020), 10 bivalves (4 unionids) in the Lipno dam reservoir in the Czech Republic (Dvořák & Beran 2004, Beran & Dvořák 2006), or 14 bivalves (4 unionids) in each of the two studied dam reservoirs in Poland: the Zegrzyński reservoir and the Sulejów reservoir (Jurkiewicz-Karnkowska 2004), only very scattered occurrences of three species (2 unionids) were found in the Orava reservoir. The Zemplínská Šírava reservoir and the two reservoirs in Poland are situated in the valleys of bigger rivers so the higher number of bivalves is understandable, but the Lipno reservoir lies at an even higher altitude than the Orava reservoir and yet its number of bivalves is significantly higher. It is possible that some smaller bivalves of the family Sphaeriidae may occur in tributaries of the Orava reservoir. A similar phenomenon was observed in the case of the Švihov dam reservoir in the Czech Republic in the Elbe River basin, more than 100 km away from its known range mentioned in Lisický (1991) and Horská et al. (2020). Its unintentional introduction by humans, in connection with recreational activities, or by migratory birds, can be considered. The existence of dam reservoirs as sites, which attract recreational activities and/or are important for migratory birds may favour introduction of this species and also of other molluscs occurring in the reservoir. A similar phenomenon was observed in the case of the Švihov dam reservoir in the Czech Republic in the Elbe River basin, more than 100 km away from the native populations of V. acerosus in the Danube River basin in Southern Moravia (Beran et al. 2019). This dam reservoir is a source of drinking water and entry is not allowed, so the introduction by migratory birds is more likely than by humans pursuing recreational activities. The occurrence of two non-native species (P. antipodarum, P. acuta) outside their known range in Slovakia confirms their continuing spread.

ACKNOWLEDGEMENTS

I thank Tomáš Čejka for providing publications with historical data, Katrín Schniebs for identification of R. lagotis and the anonymous reviewers for their valuable comments.
