Characterization of Hermitian symmetric spaces by fundamental forms

Jun-Muk Hwang\(^1\) and Keizo Yamaguchi\(^2\)

1 Introduction

In [L1] and [L2], Landsberg proved the following

**Theorem A (Landsberg)** Let \( H \) be an irreducible compact Hermitian symmetric space of rank 2, different from the hyperquadric \( Q_n \subset \mathbb{P}_{n+1} \). Let \( H \subset \mathbb{P}_N \) be a minimal non-degenerate equivariant embedding, equivalently, an embedding of \( H \) in \( \mathbb{P}_N \) defined by the complete linear system associated to the ample generator of \( \text{Pic}(H) \cong \mathbb{Z} \). Let \( M \subset \mathbb{P}_N \) be a (not necessarily closed) complex sub-manifold with \( \dim(M) = \dim(H) \) and \( x \in M \) be a point in a neighborhood of which all the integer-valued differential invariants of \( M \) remain constant. If the second fundamental form of \( M \) at \( x \) is isomorphic to the second fundamental form of \( H \) at a point, then \( M \) is projective-linearly equivalent to an open subset of \( H \).

For the reducible case, he proved ([L1, Theorem 1])

**Theorem B (Landsberg)** Let \( M \subset \mathbb{P}_N \) be a complex sub-manifold and \( x \in M \) be a point in a neighborhood of which all the integer-valued differential invariants of \( M \) remain constant. If the second fundamental form of \( M \) at \( x \) is isomorphic to the second fundamental form of a Segre variety \( \mathbb{P}_{n_1} \times \mathbb{P}_{n_2} \subset \mathbb{P}_{(n_1+1)(n_2+1)-1} \), with \( n_1, n_2 \geq 2 \), then \( M \) is projective-linearly equivalent to an open subset of the Segre variety.

We refer the readers to [GH] and [L1] for historical background on problems of this kind and the relation of such questions with other problems in projective algebraic geometry.

Our main result is a generalization of Theorem A to higher-order embeddings and to Hermitian symmetric spaces of higher rank. Precisely, we are going to prove

**Theorem 1** Let \( H \) be a compact Hermitian symmetric space which contains neither \( \mathbb{P}_n, n \geq 1 \) nor \( Q_n, n \geq 2 \) as an irreducible factor. Let \( H \subset \mathbb{P}_N \) be a non-degenerate equivariant embedding, or equivalently, the embedding by a complete linear system on \( H \). Let \( M \subset \mathbb{P}_N \) be a (not necessarily closed) complex sub-manifold with \( \dim(M) = \dim(H) \) and \( x \in M \) be a point in a neighborhood of which all the integer-valued differential invariants of \( M \) remain constant. If the fundamental forms of \( M \) at \( x \) are isomorphic to the fundamental forms of \( H \) at a point, then \( M \) is projective-linearly equivalent to an open subset of \( H \).

Note that for the minimal embedding of a Hermitian symmetric space of rank 2, the second osculating space spans the whole \( \mathbb{P}_N \), so the higher fundamental forms are identically zero. Thus Theorem A is a special case of Theorem 1.

It is well-known that the equivariant embeddings of \( Q_n \subset \mathbb{P}_{n+1}, n \geq 2 \) and \( \mathbb{P}_n, n \geq 1 \) cannot be characterized by their fundamental forms. For example, for the standard embedding of \( Q_n \) in \( \mathbb{P}_{n+1} \) and the second Veronese embedding of \( \mathbb{P}_n \), one has to consider the cubic invariants in

addition to the fundamental forms ([JM], [L1, Theorem 4]). However, even when $H$ contains $P_n$ or $Q_n$ as an irreducible factor, there are cases where our method can be applied. As an example, we will prove the following generalization of Theorem B:

**Theorem 2** Let $M \subset P^N$ be a complex sub-manifold and $x \in M$ be a point in a neighborhood of which all the integer-valued differential invariants of $M$ remain constant. If the fundamental forms of $M$ at $x$ is isomorphic to those of a Segre variety $P_{n_1} \times \cdots \times P_{n_m} \subset P^N, N = \prod_{i=1}^m (n_i + 1) - 1, n_i \geq 2$, then $M$ is projective-linearly equivalent to an open subset of the Segre variety.

For the proof of Theorem 1 and Theorem 2, we use the theory of linear differential equations modelled on Hermitian symmetric spaces due to Y. Se-ashi [S]. This theory reduces the problem to the vanishing of certain Spencer cohomology groups by a reduction theory of principal bundles. In this sense, the proof is fundamentally different from [L1] and [L2], which depend on certain moving frame computation. Of course, one may say that the moving frame method and the reduction theory of principal bundles are just two different formulations of the same procedure. However, we believe that the more conceptual viewpoint of [S] is essential in the treatment of the higher rank and the higher order cases, because a simple-minded moving frame computation would get complicated heavily. We hope that presenting such a geometric application would make the deep work [S] more widely appreciated. See [SYY] for another application.

In Section 2, we will define the fundamental forms in the setting of [S]. In Section 3, an invariant-theoretic result concerning the fundamental forms of the Hermitian symmetric space is proved, which makes it possible to apply the result of [S] in our problem. This reduces the problem to a calculation of Lie algebra cohomology. The computation of cohomology group will be done using Kostant’s harmonic theory in Section 4. This computation had already appeared in [SYY] in the irreducible case.

### 2 Fundamental forms as a system of linear differential equations

We start with recalling some definitions from [S] (see also [SYY]). Let $M$ be a connected complex manifold. We denote by $T$ and $T^*$ the (holomorphic) tangent and the cotangent bundle of $M$ respectively. For a line bundle $E$ on $M$, we denote by $J_p(E)$ the bundle of $p$-jets of $E$. Its fiber at a point $x \in M$ is

$$J_p^x(E) := \mathcal{O}_x(E)/\left(\mathcal{O}_x(E) \otimes m_x^{p+1}\right).$$

We identify $J^0(E) = E$. For each pair of non-negative integers $p \geq q$, we have a natural projection $\pi^p_q : J^p(E) \to J^q(E)$. For a section $s$ of $E$, denote its $p$-jet at $x$ by $j^p_x(s) \in J^p_x(E)$. We have a natural exact sequence of vector bundles

$$0 \longrightarrow \text{Sym}^p T^*(M) \otimes E \longrightarrow J^p(E) \xrightarrow{\pi^p_{p-1}} J^{p-1}(E) \longrightarrow 0.$$

At each $x \in M$, we have the induced exact sequence of vector spaces of the fibers at $x$

$$0 \longrightarrow \text{Sym}^p T^*_x \otimes E_x \longrightarrow J^p_x(E) \xrightarrow{\pi^p_{p-1}} J^{p-1}_x(E) \longrightarrow 0.$$

2
A sub-bundle $R$ of $J^p(E)$ is called a \textit{system of linear differential equations of order $p$} on $E$. A section $s$ of $E$ over an open subset $U \subset M$ satisfying $j^p_x(s) \in R_x$ for each $x \in U$ is called a \textit{solution} of $R$ over $U$. For each non-negative integer $r \leq p$, the subspace $\sigma^r_x(R) \subset \text{Sym}^rT^*_x$ corresponding to $\pi^p_x(R_x) \cap (\text{Sym}^rT^*_x \otimes E_x)$ under an identification $E_x \cong \mathbb{C}$ is called the $r$-\textit{th symbol} of $R$ at $x$. It is independent of the choice of the identification $E_x \cong \mathbb{C}$. The direct sum $\sigma_x(R) = \bigoplus_{r=0}^p \sigma^r_x(R)$ is called the \textit{symbol} of $R$ at $x$. The system $R \subset J^p(E)$ is said to be of \textit{finite type} if $\sigma^0_x(R) = 0$ for general $x \in X$. $R$ is said to be \textit{integrable} if for each $\eta \in R_x$, there exists a solution $s$ over a neighborhood of $x$ for which $j^p_x(s) = \eta$. Such a solution is uniquely determined by $\eta$ when $R$ is of finite type.

Let $R$ (resp. $R'$) be a system of order $p$ on a line bundle $E$ (resp. $E'$) on a complex manifold $M$ (resp. $M'$). We say that the symbol of $R$ at $x \in M$ is isomorphic to the symbol of $R'$ at $y \in M'$ if there exists a linear isomorphism $\theta : T_x \to T_y$ such that the induced linear isomorphism $\theta^* : \text{Sym}^rT^*_x \to \text{Sym}^rT^*_y$ sends $\sigma^r_x(R)$ to $\sigma^r_y(R')$ for each $0 \leq r \leq p$. We say that $R$ is \textit{locally equivalent} to $R'$ if there exists an open subset $U \subset M$ (resp. $U' \subset M'$) and a line bundle isomorphism $\varphi : E|_U \to E'|_{U'}$ such that the induced bundle isomorphism $J^p(\varphi) : J^p(E)|_U \to J^p(E')|_{U'}$ maps $R|_U$ onto $R'|_{U'}$.

Many interesting examples of integrable systems of linear differential equations of finite order arises from the projective differential geometry (e.g. [W]). In modern terms, it can be presented as follows. Let $M \subset \mathbb{P}^N$ be a non-degenerate complex sub-manifold. Let $E$ be the line bundle on $M$ defined by the restriction of the hyperplane line bundle of $\mathbb{P}^N$ and $\Sigma$ be the $(N + 1)$-dimensional space of sections of $E$ coming from the sections of the hyperplane line bundle. Let $p > 0$ be a positive integer such that an element of $\Sigma$ having a zero of order $\geq p$ at a point of $M$ is identically zero. Define $R_x \subset J^p_x(E)$ by

$$R_x := \{j^p_x(s)|s \in \Sigma\}.$$ 

Then over a Zariski-open subset $M^o$ of $M$,

$$R := \bigcup_{x \in M^o} R_x$$

defines a sub-bundle of $J^p(E)|_{M^o}$, called the \textit{hyperplane system} on $M$. By the construction, $R$ is of finite type and integrable. In fact,

$$\pi^p_x(R_x) = \{j^p_x(s)|s \in \Sigma\}.$$ 

**Proposition 1** Let $M$ and $M'$ be two non-degenerate sub-manifolds of $\mathbb{P}^N$. Let $R$ (resp. $R'$) be the hyperplane system on $M$ (resp. $M'$). Assume that $R$ and $R'$ are of the same order. Then $R$ and $R'$ are locally equivalent if and only if there exists a projective linear transformation sending an open subset of $M$ onto an open subset of $M'$.

**Proof.** The ‘if’ part is trivial. Let us prove the ‘only if’ part. Let $E$ (resp. $E'$) be the restriction of the hyperplane line bundle on $M$ (resp. $M'$). Let $\Sigma$ (resp. $\Sigma'$) be the sections of $E$ (resp. $E'$) coming from the global sections of the hyperplane line bundle on $\mathbb{P}^N$. If $R$ and $R'$ are locally equivalent, there exists an open subset $U \subset M$ (resp. $U' \subset M'$) and an isomorphism of line bundles $\varphi : E|_U \to E'|_{U'}$ mapping $R|_U$ onto $R'|_{U'}$. The solutions of $R|_U$ are sent to the solutions of $R'|_{U'}$. By the assumption that $R$ and $R'$ are of finite type, every local solution of
For $x \in M^o$, the symbol $\sigma^r_x(R) \subset \text{Sym}^r T^*_x$ is called the \textbf{r-th fundamental form} of $M$ at $x$ and is denoted by $F^r_x(M)$. We decree $F^r_x(M) = 0$ for $r \geq p$. For two sub-manifolds $M, M' \subset \mathbb{P}_N$, we say that the fundamental forms of $M$ at $x \in M$ are isomorphic to the fundamental forms of $M'$ at $y \in M'$, if there exists a linear isomorphism $\theta : T_x \to T_y$ such that the induced linear map $\theta^r : \text{Sym}^r T^*_x \to \text{Sym}^r T^*_y$ sends $F^r_x(M)$ to $F^r_y(M')$ for each $r \geq 0$.

\textbf{Remark} Usually, the $r$-th fundamental form of $M$ at $x$ is defined as a linear map $\text{Sym}^r T_x \to N^r_x$ where $N^r_x$ is the $r$-th normal space at $x$ (e.g. [GH]). Our $F^r_x(M) \subset \text{Sym}^r T^*_x$ is the image of the dual of this linear map.

\section{Fundamental forms of Hermitian symmetric spaces}

We start with a few definitions regarding representations of abelian Lie algebras on graded vector spaces.

Let $W = \bigoplus^p_{r=0} W_r$ be a finite-dimensional graded vector space with $\dim W_0 = 1$. For each integer $k$, define

$$\mathfrak{gl}(W)_k := \{X \in \mathfrak{gl}(W) | X(W_r) \subset W_{k+r} \text{ for all } r\}.$$ 

Let $V$ be a finite dimensional vector space and $\mu : V \to \mathfrak{gl}(W)$ be a representation of the abelian Lie algebra $V$ such that $\mu(V) \subset \mathfrak{gl}(W)_{-1}$. Setting $p_{-1} = \mu(V)$, define inductively for each $k \geq 0$,

$$p_k := \{X \in \mathfrak{gl}(W)_k | [p_{-1}, X] \subset p_{k-1}\}.$$ 

Then the graded Lie subalgebra $p = \bigoplus_{k=-1}^\infty p_k$ of $\mathfrak{gl}(W)$ is called the \textbf{prolongation} of $\mu$. For each non-negative integer $r$, define a homomorphism $\chi^\mu_r : W_r \to \text{Sym}^r V^* \otimes W_0$ by

$$\chi^\mu_r(w)(X_1, \ldots, X_r) := \mu(X_1) \cdots \mu(X_r)(w)$$

for $w \in W_r$ and $X_1, \ldots, X_r \in V$. The right hand side is symmetric in $X_1, \ldots, X_r$ because $\mu$ is a representation of the abelian Lie algebra $V$. After fixing an identification $W_0 = \mathbb{C}$, we denote by $\chi^\mu : W \to \bigoplus_{r=0}^p \text{Sym}^r V^*$ the graded vector space homomorphism obtained as the sum of $\bigoplus_{r=0}^p \chi^\mu_r$. The homomorphism $\chi^\mu$ is called the \textbf{symbol map} of the representation $\mu : V \to \mathfrak{gl}(W)_{-1}$. The following proposition is obvious.

\textbf{Proposition 2} For $X \in V$, let $\iota(X) : \text{Sym}^r V^* \to \text{Sym}^r V^*$ denote the inner multiplication by $X$. Then the image of $\chi^\mu$ is invariant under $\iota(X)$ for any $X \in V$ and

$$\iota(X) \circ \chi^\mu(w) = \chi^\mu(\mu(X) \cdot w)$$

for every $X \in V$ and $w \in W$.

Now let $l = l_{-1} + l_0 + l_1$ be a semi-simple graded Lie algebra. Let $L$ be a connected Lie group with Lie algebra $l$ and $L'$ be a connected subgroup of $L$ with Lie algebra $l' = l_0 + l_1$. Then the homogeneous space $L/L'$ is a compact Hermitian symmetric space. Conversely, for any compact Hermitian symmetric space, let $l$ be the Lie algebra of global holomorphic vector fields and $l'$ be
the subalgebra consisting of vector fields vanishing at a base point. Then there exists a grading 
\( l = l_{-1} + l_0 + l_1 \) such that \( l' = l_0 \oplus l_1 \).

Given a non-degenerate equivariant embedding of the Hermitian symmetric space \( L/L' \subset P S^* \)
for a finite-dimensional vector space \( S \), we get a faithful irreducible representation \( \rho : l \to gl(S) \)
such that
\[
S_0 := \{ s \in S | \rho(l_{-1})(s) = 0 \}
\]
is 1-dimensional. Define for \( r \geq 0 \),
\[
S_{r+1} := \rho(l_1)(S_r).
\]
There exists \( p > 0 \) such that \( S_r \neq 0 \) for \( r = 0, 1, \ldots, p - 1 \) and \( S_r = 0 \) for \( r \geq p \). Moreover
\[
S = \bigoplus_{r=0}^{p} S_r.
\]
Set \( V := l_{-1} \) and let \( \nu : V \to gl(S) \) be the representation obtained by restricting \( \rho : l \to gl(S) \)
to \( l_{-1} \). Then \( \nu : V \to gl(S)_{-1} \) with respect to the grading \( S = \bigoplus_{r=0}^{p} S_r \).

We recall the following result on the prolongation of \( \nu \).

**Proposition 3** ([S, Proposition 4.4.1], or [SYY, (2.5)] for the irreducible case) Regard
\( l \) as a subalgebra of \( gl(S) \) by the given faithful irreducible representation \( \rho : l \to gl(S) \). Let \( z \) be
the centralizer of \( l \) in \( gl(S) \). For the representation \( \nu : V := l_{-1} \to gl(S)_{-1} \), the prolongation is
\( p_{-1} \cong V \) (i.e. \( \nu \) is injective), \( p_0 = l_0 + z, p_1 = l_1 \) and \( p_k = 0 \) for \( k \geq 2 \). In particular, \( p \) is a
reductive graded Lie algebra whose semi-simple part is the graded semi-simple Lie algebra \( l \).

The following result on the symbol map of \( \nu \) is contained in [S]. Note that \( l_{-1} \) is naturally
identified with the tangent space of the Hermitian symmetric space \( L/L' \) at the base point.

**Proposition 4** Let \( V := l_{-1} \) and \( \nu : V \to gl(S)_{-1} \) be the representation obtained by restricting
\( \rho : l \to gl(S) \) with respect to the grading \( S = \bigoplus_{r=0}^{p} S_r \). Then \( \chi^\nu : \bigoplus_{r=0}^{p} S_r \to \bigoplus_{r=0}^{p} \text{Sym}^r V^* \) is
injective and the image \( \chi^\nu(S_r) \subset \text{Sym}^r V^* \) coincides with the \( r \)-th fundamental form \( F_\nu^r(L/L) \subset \text{Sym}^r(L_{-1}) \) of \( L/L' \subset P S^* \).

**Proof.** The injectivity of \( \chi^\nu \) is [S, Proposition 4.3.1]. That the image \( \chi^\nu(S_r) \subset \text{Sym}^r V^* \)
coincides with the \( r \)-th fundamental form is [S, Proposition 2.4.1]. \( \square \)

Now we regard \( S = \bigoplus_{r=0}^{p} S_r \) as a graded vector subspace of \( \bigoplus_{r=0}^{p} \text{Sym}^r V^* \) by the injection
\( \chi^\nu \). By Proposition 2, the action of \( V \) on \( S \) by \( \nu \) coincide with the restriction of the inner
multiplication. The following invariant-theoretic result implies the ‘rigidity’ of the fundamental
forms of Hermitian symmetric spaces.

**Proposition 5** Regard \( S = \bigoplus_{r=0}^{p} S_r \) as a graded subspace of \( \bigoplus_{r=0}^{p} \text{Sym}^r V^* \) as explained above.
Let \( P = \bigoplus_{r=0}^{p} P_r \) be a graded subspace of \( \bigoplus_{r=0}^{p} \text{Sym}^r V^* \) which has the same discrete invariants
as \( S \) under the action of \( GL(V) \). Then \( P \) is in the \( GL(V) \)-orbit of \( S \). In other words, there exist
finitely many \( GL(V) \)-invariant \( Z \)-valued functions on the Grassmannian \( Gr(\dim S, \bigoplus_{r=0}^{p} \text{Sym}^r V^*) \)
of \( (\dim S) \)-dimensional subspaces in \( \bigoplus_{r=0}^{p} \text{Sym}^r V^* \), such that if all these functions have the same
values on \( P \) and \( S \), then \( P \) is in the orbit of \( S \) under the \( GL(V) \)-action on the Grassmannian.

**Proof.** By Proposition 2, \( S \) is invariant under \( \iota(X) \) for all \( X \in V \). Since \( \dim \iota(X) P \) and
\( \dim(P \cap \iota(X) P) \) must be equal to the corresponding dimensions for \( S \), we conclude that \( P \)
is also invariant under \( \iota(X) \). Moreover the action of \( \iota(X) \) and \( \iota(Y) \) on \( P \) commute for any \( X, Y \in V \). Thus we have a representation \( \mu : V \to \mathfrak{gl}(P)_{-1} \). The dimension of the prolongation of \( \mu \) and the dimension of the prolongation of \( \nu : V \to \mathfrak{gl}(S) \) are equal by the assumption on \( P \). So are the dimensions of their radicals. This implies, by Proposition 3, the prolongation \( p = p_{-1} + p_0 + p_1 + \cdots \) of \( \mu \) is reductive and isomorphic to \( l_{-1} + (l_0 + z) + l_1 \). By the same reasoning, the action of the prolongation \( p \) on \( P \) is isomorphic to the irreducible representation of \( l \) on \( S \). In particular, \( \mu : V \to \mathfrak{gl}(P)_{-1} \) is isomorphic to \( \nu : V \to \mathfrak{gl}(S)_{-1} \) under a linear automorphism of \( V \) and a graded vector space isomorphism \( P \cong S \). Consider \( \chi^\mu : P \to \bigoplus_{r=0}^p \text{Sym}^r V^* \). The image \( \chi^\mu(P) \subset \bigoplus_{r=0}^p \text{Sym}^r V^* \) is completely determined by the structure of \( P \) as a \( V \)-module. Thus \( \dim \chi^\mu(P) = \dim \chi^\nu(S) \) and \( \chi^\mu(P) \) is in the \( GL(V) \)-orbit of \( \chi^\nu(S) \). But by our definition of \( S \) as the subspace of \( \bigoplus_{r=0}^p \text{Sym}^r V^* \), \( \chi^\nu(S) = S \). Since \( \dim \chi^\mu(P) \cap P \) is an integer-valued invariant of \( P \), we conclude \( P = \chi^\mu(P) \) is in the \( GL(V) \)-orbit of \( \chi^\nu(S) = S \). □

4 Vanishing of Spencer cohomology

Let \( l = l_{-1} + l_0 + l_1 \) be a graded semi-simple Lie algebra associated to a Hermitian symmetric space as explained in Section 3. We recall the description of the gradation of \( l \) in terms of the root system. Let \( h \subset l_0 \) be a Cartan subalgebra of \( l \). Then there exists a unique element \( Z \in h \), called the characteristic element, with the property that

\[
l_i = \{ X \in l \mid [Z, X] = iX \}
\]

for each \( i = -1, 0, 1 \). Choose a simple root system \( \Delta = \{ \alpha_1, \ldots, \alpha_\ell \} \) such that \( \alpha_\ell(Z) \geq 0 \) for all \( \ell, \ldots, \ell' \). Then \( Z \) determines a partition \( \Phi^+ = \Phi_0^+ \cup \Phi_1^+ \) of the set of positive roots by \( \Phi_k^+ = \{ \alpha \in \Phi^+ | \alpha(Z) = k \} \) for \( k = 0, 1 \), such that

\[
l_{-1} = \bigoplus_{\alpha \in \Phi_1^+} g_{-\alpha} \\
l_0 = h \oplus \bigoplus_{\alpha \in \Phi_0^+} (g_\alpha \oplus g_{-\alpha}) \\
l_1 = \bigoplus_{\alpha \in \Phi_1^+} g_\alpha
\]

where \( g_\alpha \) is the root space. Define

\[
\Delta_1 = \{ \alpha_{i_1}, \ldots, \alpha_{i_m} \} := \{ \alpha \in \Delta \mid \alpha(Z) = 1 \}.
\]

Recall

\[
<\beta, \gamma> = \frac{2(\beta, \gamma)}{(\gamma, \gamma)}
\]

for \( \beta, \gamma \in h^* \). Let \( \lambda_1, \ldots, \lambda_\ell \) be the fundamental weights and \( h_{\alpha_1}, \ldots, h_{\alpha_\ell} \) be the co-roots, namely,

\[
<\lambda_i, \alpha_j> = \delta_{ij}, \quad \beta(h_{\alpha_i}) = <\beta, \alpha_i> \quad \text{for all } \beta \in h^*.
\]

By a direct computation, we have

**Lemma 1** Suppose \( \lambda_{i_1} + \cdots + \lambda_{i_m} = \sum_{i=1}^r a_i \alpha_i \). Then \( Z = \sum_{i=1}^r a_i h_{\alpha_i} \).
Let \( W \) be the Weyl group of the root system \( \Phi \). For an element \( \sigma \in W \), put \( \Phi_\sigma = \sigma(\Phi^+) \cap \Phi^+ \). Define
\[
W^0 := \{ \sigma \in W \mid \Phi_\sigma \subset \Phi^+_1 \}
\]
\[
W^0(1) := \{ \sigma \in W^0 \mid \sharp(\Phi_\sigma) = 1 \}
\]
where \( \sharp(\Phi_\sigma) \) is the number of roots in \( \Phi_\sigma \). For \( \alpha_i \in \Delta \), let \( \sigma_i \in W \) be the corresponding reflection.

**Lemma 2** \( W^0(1) = \{ \sigma_\alpha \mid \alpha \in \Delta_1 \} = \{ \sigma_{i_1}, \ldots, \sigma_{i_m} \} \).

**Proof.** The inclusion \( \{ \sigma_{i_1}, \ldots, \sigma_{i_m} \} \subset W^0(1) \) is immediate. By [H, 10.3 Lemma A], elements of \( W^0(1) \) are simple reflections. If \( \sigma_i \in W^0(1) \), then \( \Phi_{\sigma_i} = \{ \sigma_i \} \) and \( \Phi_\sigma \subset \Phi^+_1 \). Thus \( \alpha_i \in \Delta_1 \). \( \square \)

For a finite-dimensional \( l \)-module \( \Gamma \) for which the weights of \( Z \) are integers, let \( \Gamma_p \) be the subspace of \( \Gamma \) consisting of eigenvectors of \( Z \) with eigenvalue \( p \in \mathbb{Z} \). Set \( C^{p,q} := \Lambda^q(L^-_1)^* \otimes \Gamma_{p-1} \) and define \( \partial : C^{p,1} \to C^{p-1,2} \) by
\[
\partial c(X_0, X_1) = X_0 \cdot c(X_1) - X_1 \cdot c(X_0)
\]
for \( c \in C^{p,1} = (L^-_1)^* \otimes \Gamma_{p-1} \) and \( \partial : C^{p+1,0} \to C^{p,1} \) by
\[
\partial c(X) = X \cdot c
\]
for \( x \in \Gamma_p \). For each integer \( p \), the \( p \)-th **Spencer cohomology group** associated to \( \Gamma \) is defined by
\[
H^{p,1}(L^-_1, \Gamma) := \frac{(\text{Ker} \partial : C^{p,1} \to C^{p-1,2})}{(\text{Im} \partial : C^{p+1,0} \to C^{p,1})}.
\]
They give the decomposition of the Lie algebra cohomology group
\[
H^1(L^-_1, \Gamma) = \oplus_p H^{p,1}(L^-_1, \Gamma)
\]
which is just the \( Z \)-eigenspace decomposition.

Given a faithful irreducible \( l \)-module \( S \) with \( \dim S_0 = 1 \), \( g \subset \mathfrak{gl}(S) \) be the prolongation of \( L^-_1 \)-action on \( S \) as defined in the last section. Let \( g^\perp \subset \mathfrak{gl}(S) \) be the orthogonal complement with respect to the Killing form on \( \mathfrak{gl}(S) \). Then \( g^\perp \) is an \( l \)-module where the weights of \( Z \) are integers. So \( H^{p,1}(L^-_1, g^\perp) \) makes sense.

Let \( R \) be a system of linear differential equations of order \( p \) on a complex manifold \( M \). Given a graded subspace \( S = \bigoplus_{i=0}^p S_i \subset \text{Sym}^\bullet V \) for a vector space \( V \), \( \dim V = \dim M \), we say that the symbol \( \sigma_x(R) \) is isomorphic to \( S \) if there exists a linear isomorphism \( \psi : T^*_x \to V \) such that the induced graded linear isomorphism \( \text{Sym}^\bullet T^*_x \to \text{Sym}^\bullet V \) sends \( \sigma_x(R) \) onto \( S \).

We will reduce the proof of Theorem 1 and Theorem 2 to the vanishing of certain Spencer cohomology groups by using the following result of Y. Se-ashi. Theorem 3 appeared as Theorem 5.1.2, Theorem 5.2.2 and Theorem 5.3.1 in [S]. We recommend [SYY, 2.4] for an over-view of its proof, where it appeared as ‘Theorem A’.

**Theorem 3 (Se-ashi)** Let \( H \subset P_N \) be an equivariantly embedded Hermitian symmetric space and \( F = \bigoplus_{r=0}^p F^r \) be the fundamental forms at a point of \( H \). Assume that \( H^{p,1}(L^-_1, g^\perp) = 0 \) for all \( p \geq 1 \). Suppose a system \( R \) on a line bundle \( E \) of a complex manifold \( M \) has its symbol
at each point \( x \in M \) isomorphic to \( F \). Then \( R \) is locally equivalent to the hyperplane system on \( H \subset \mathbb{P}_N \).

For the computation of the Spencer cohomology we will use Kostant’s result. The following is a translation of [K, Theorem 5.14] into our situation (cf. [SYY, 2.5 Theorem B]). See also [Y, 5.1] for a stream-lined review of Kostant theory. Note that \( \mathfrak{l}_1 = (\mathfrak{l}_1)^{\ast} \) by the Killing form.

Theorem 4 (Kostant) Let \( \Gamma \) be an irreducible \( \mathfrak{l} \)-module and \( \gamma \) be its lowest weight. Then we have an \( \mathfrak{l}_0 \)-module decomposition

\[
H^1(\mathfrak{l}_1, \Gamma) = \bigoplus_{\sigma \in W^0(1)} \mathcal{H}^{\xi_\sigma}
\]

where \( \mathcal{H}^{\xi_\sigma} \) is the irreducible \( \mathfrak{l}_0 \)-module with the lowest weight \( \xi_\sigma := \sigma(\gamma) + \alpha \) for the simple root \( \alpha \) satisfying \( \sigma = \sigma_\alpha \).

This has the following consequence for the Spencer cohomology groups.

Proposition 6 Let \( Z \in \mathfrak{h} \) be the characteristic element of the graded Lie algebra \( \mathfrak{l} \). Let \( \Gamma \) be an irreducible \( \mathfrak{l} \)-module such that the weights of \( Z \) on \( \Gamma \) are integers. Let \( \gamma \) be the lowest weight of \( \Gamma \). Then \( H^{p,1}(\mathfrak{l}_1, \Gamma) \neq 0 \) only if \( p - 1 = \sigma_{ik}(\gamma)(Z) \) for some \( i_k \).

Proof. \( H^{p,1}(\mathfrak{l}_1, \Gamma) \) is the eigenspace of \( Z \) with eigenvalue \( p \). By Theorem 4, it is non-zero if there exists \( \sigma_i \in W^0(1) \) such that

\[
p = \xi_{\sigma_i}(Z) = \sigma_i(\gamma)(Z) + \alpha_i(Z).
\]

Thus the result follows from \( W^0(1) = \{ \sigma_{i_1}, \ldots, \sigma_{i_m} \} \) by Lemma 2 and \( \alpha_{ik}(Z) = 1 \). \( \square \)

The following is an honest generalization of [SYY, Theorem 2].

Proposition 7 Let \( \mathfrak{l} = \mathfrak{l}_1 + \mathfrak{l}_0 + \mathfrak{l}_1 \) be the graded semi-simple Lie algebra associated to a Hermitian symmetric space which contains neither a projective space nor a hyperquadric as an irreducible factor. Then for any irreducible \( \mathfrak{l} \)-module \( \Gamma \),

\[
H^{p,1}(\mathfrak{l}_1, \Gamma) = 0 \text{ for all } p \geq 1.
\]

Proof.

\[
\sigma_{ik}(\gamma)(Z) = (\gamma - \langle \gamma, \alpha_{ik} \rangle \alpha_{ik})(Z)
= \gamma(Z) - \langle \gamma, \alpha_{ik} \rangle.
\]

By Lemma 1,

\[
\sigma_{ik}(\gamma)(Z) = (a_{ik} - 1) \langle \gamma, \alpha_{ik} \rangle + \sum_{i \neq i_k} a_i \langle \gamma, \alpha_i \rangle.
\]

Since \( \gamma \) is the lowest weight, we have \( \langle \gamma, \alpha_i \rangle \leq 0 \) for \( i = 1, \ldots, \ell \) and \( \langle \gamma, \alpha_j \rangle < 0 \) for some \( j \). Since \( a_i \) is an entry of the inverse matrix of the Cartan matrix, \( a_i > 0 \). In particular, if \( a_{ik} > 1 \), then \( \sigma_{ik}(\gamma)(Z) < 0 \) for every \( \gamma \). The only cases when \( a_{ik} \leq 1 \) are the following (e.g. [H, 13.2 Table 1]).
• $a_{ik} = \frac{\ell}{\ell + 1}$ when $\alpha_{ik}$ is the root $\alpha_1$ of $A_\ell, \ell \geq 1$.

• $a_{ik} = 1$ when $\alpha_{ik}$ is the root $\alpha_2$ of $A_3$.

• $a_{ik} = 1$ when $\alpha_{ik}$ is the root $\alpha_1$ of $B_\ell, \ell \geq 2$.

• $a_{ik} = 1$ when $\alpha_{ik}$ is the root $\alpha_1$ of $D_\ell, \ell \geq 4$.

In these cases, the corresponding irreducible factor of the Hermitian symmetric space is a projective space or a hyperquadric. □

**Proof of Theorem 1.** Applying Proposition 7 to each irreducible factor of $g^\perp$, we see that $H^{p,1}(\mathbb{L}_-, g^\perp) = 0$ for all $p \geq 1$. By Proposition 5, the fundamental forms of $M$ at each point of a neighborhood of $x$ are isomorphic to the fundamental forms of $H$ at a point. Thus Theorem 1 follows from Theorem 3 and Proposition 1. □

To prove Theorem 2, let us study the corresponding $l$-modules. Let $l = \mathfrak{sl}_{n_1 + 1} \oplus \cdots \oplus \mathfrak{sl}_{n_m + 1}$ with $n_i \geq 2$ for all $i = 1, \ldots, m$. Let us denote the simple roots of $\mathfrak{sl}_{n+j+1}$ by $\{\alpha_{ij}^1, \ldots, \alpha_{ij}^{n_j}\}$ using the standard enumeration of simple roots of the simple Lie algebra of type $A$. For the Hermitian symmetric space $P_{n_1} \times \cdots \times P_{n_m}$, the corresponding gradation of $l$ has

$$\Delta_l = \{\alpha_{1}^1, \alpha_{1}^2, \ldots, \alpha_{1}^{m}\}.$$

The fundamental weights of $l$ are denoted by

$$\lambda_{1}^1, \ldots, \lambda_{n_1}^1, \lambda_{2}^1, \ldots, \lambda_{n_2}^1, \ldots, \lambda_{1}^{m}, \ldots, \lambda_{n_m}^{m}.$$

Let $U^j = C^{n_j + 1}$ be the basic representation space of $\mathfrak{sl}_{n+j+1}$ corresponding to the fundamental weight $\lambda_j^1$. Let $S := (U^1)^* \otimes \cdots \otimes (U^m)^*$ be the basic representation space of $l$. Using $\mathfrak{gl}( (U^1)^*) = C \cdot \text{Id} + \mathfrak{sl}( (U^1)^*)$ and $\mathfrak{sl}( (U^1)^*) \cong \mathfrak{sl}(U^1)$, we have the $l$-module decomposition

$$\mathfrak{gl}(S) = \left( C \cdot \text{Id} + \mathfrak{sl}(U^1) \oplus \cdots \oplus \mathfrak{sl}(U^m) \right) + g^\perp$$

where $g^\perp$ is a sum of tensor products of the form $\mathfrak{sl}(U^{i_1}) \otimes \cdots \otimes \mathfrak{sl}(U^{i_k})$ for some $k \geq 2$. By Proposition 1, Proposition 5 and Theorem 3, the proof of Theorem 2 is reduced to the following.

**Proposition 8** In the above notation, $H^{p,1}(\mathbb{L}_-, g^\perp) = 0$ for all $p \geq 1$.

**Proof.** Let $\gamma$ be the lowest weight of $\mathfrak{sl}(U^{i_1}) \otimes \cdots \otimes \mathfrak{sl}(U^{i_k}), k \geq 2$. By Proposition 6, it suffices to show, for each $\ell = 1, \ldots, m$,

$$\gamma(Z) - \langle \gamma, \alpha_1^{i} \rangle \leq -1.$$

Since the adjoint representation $\mathfrak{sl}(U^j)$ has highest weight $\lambda_j^1 + \lambda_{n_j}$,

$$\gamma = - \sum_{j=1}^{k} (\lambda_{1}^{i_j} + \lambda_{n_j}^{i_j}).$$

When $\lambda_{1}^1 = \sum_{i=1}^{n_j} a_{i}^j \alpha_{i}^j$, Lemma 1 says

$$Z = \sum_{j=1}^{m} \sum_{i=1}^{n_j} a_{i}^j h_{\alpha_{i}^j}.$$
Using (e.g. from [H, 13.2 Table 1]) \( a_{i_j}^j = \frac{n_j}{n_j + 1} \) and \( a_{n_j}^j = \frac{1}{n_j + 1} \), we have

\[
\gamma(Z) = -\sum_{j=1}^k (a_{i_j}^j + a_{n_j}^i) = -k
\]

while

\[
-<\gamma, \alpha_\ell^i> = <\lambda_{i_j}^i + \lambda_{n_j}^i, \alpha_1^i> = 1 \text{ when } \ell = i_j \text{ and }
\]

\[
-<\gamma, \alpha_\ell^i> = 0 \text{ when } \ell \neq i_1, \ldots, i_k.
\]

Thus \( \gamma(Z) - <\gamma, \alpha_1^i> \leq -1. \quad \blacksquare \)

**Remark** When \( n_1 = 1 \) and \( 2 \leq n_2, \ldots, n_m \), the adjoint representation \( sl(U^1) \) has highest weight \( 2\lambda_1^1 = \alpha_1^1 \). Thus \( g^\perp \) has an irreducible factor with lowest weight

\[
\gamma = -2\lambda_1 - \lambda_2 - \lambda_{n_2}^2.
\]

Then the same calculation as in the proof of Proposition 8 shows

\[
\gamma(Z) = -2a_1^1 - a_1^2 - a_{n_2}^2 = -2
\]

\[
-<\gamma, \alpha_1^i> = 2.
\]

Thus \( H^{1,1}(L_{-1}, g^\perp) \neq 0. \) It is not known whether \( P_1 \times P_{n_2} \times \cdots P_{n_m} \) with \( 2 \leq n_2, \ldots, n_m \) is determined by its fundamental forms. For \( m = 2 \), this was conjectured to be true in [L1, Section 6].
