Abstract

In this paper development and validation of a simple linear model for estimating radio refractivity from meteorological parameters are presented. Twelve months radiosonde meteorological data for Cross River state which was obtained from Nigerian Meteorological Agency (NIMET) was used to determine the radio refractivity (N). The correlation between the refractivity and the atmospheric temperature (T), atmospheric pressure (P) and relative humidity (U) were examined for twelve months dataset. The correlation values showed that temperature (T) and the product of P, H and T had the highest correlation with respect to N in all the twelve months. Based on the correlation values among the parameters examined, a simple linear model was developed to estimate the radio refractivity. In all the twelve months dataset, the mathematical model gave worst case absolute percentage error of about 3.3%. Two sample meteorological dataset from published articles were also used to validate the model. The model gave a maximum absolute percentage error of 2.46 % for the first test meteorological dataset while it gave a maximum absolute percentage error of 1.25 % for the second test meteorological dataset. In all, the linear model presented in this paper will make it easier to compute the radio refractivity from available meteorological data. The results from the validation dataset showed that the model can also be applied to every other region other than the case study area where the data for the model development were obtained.

Keywords

Refractivity, Radioclimatic Parameter, Refractivity Gradient, Radiosonde, Regression Model

1. Introduction

Most wireless communication systems rely heavily on the atmosphere as a medium for the signal transmission [1, 2, 3, 4] As such, wireless network designers are concerned about the nature of the atmosphere through which the signal propagates from the source (the transmitter) to the destination (the receiver) [5, 6, 7, 8]. Radio waves are significantly affected by the atmospheric conditions; particularly, the radio waves can be reflected, refracted, absorbed or scattered in the atmosphere [3,9, 10]. Among these effects, atmospheric refraction or bending of the radio signal path occurs due to variations of primary radioclimatic parameter, namely temperature, pressure and relative humidity [11, 12, 13, 14]. Therefore, the extent to which the radio wave path will be bent in the atmosphere is called refractivity [11, 14, 15,16].

Atmospheric refractivity has been well studied over the years and some mathematical expressions have been developed to estimate the value of refractivity [17, 18,19]. However, most of the expressions are complex and involve some nonlinear expressions. The complexity makes it more difficult to integrate the refractivity expressions into other formula to develop simple closed-form mathematical expressions needed in wireless link design. In recent years, researchers have tried to develop simple mathematical equations that can be used to estimate the radio refractivity from the atmospheric parameters. Essentially, this paper seeks to add to the body of knowledge concerning radio refractivity by developing simple linear regression model for estimating the atmospheric refractivity from the basic atmospheric parameters, namely, temperature, pressure and relative humidity. According to [18], refractivity, N is related to the temperature, pressure and relative humidity as

\[ N = K(P^2)(\sqrt{T})(\sqrt{U}) \]

where \( K = \) Constant = 0.01064097915; \( P = \) atmospheric pressure in inHg; \( T = \) atmospheric temperature in ºF; \( U = \) relative humidity in % and \( N = \) radio refractivity. Particularly, this paper upholds and employed the idea presented by [18] that refractivity is related to some form of a product of temperature, pressure and relative humidity. The proposed model in this paper is based on empirical data collected from Cross River state in Nigeria. The model is cross-validated with meteorological data obtained from published journal articles on the same issue. The benefit of such model is to simplify the computation complexity and hence reduce the resource
requirement in automated implementation of analysis requiring radio refractivity. The linear model also makes it easier to incorporate the radio refractivity into other mathematical models for parametric analysis.

2. Methodology

The radiosonde meteorological data for Cross River state, Nigeria was obtained from Nigerian Meteorological Agency (NIMET) for the twelve months in 2013. The dataset of atmospheric temperature (T), atmospheric pressure (P) and relative humidity (U) was extracted from the radiosonde meteorological data. Radio refractivity (N) was computed for each set of T, U and P for the twelve months. The correlation among the parameters N, T, U, P and TUP where TUP is the product of T, U and P were computed. The correlation values show that T and TUP had the highest correlation values with respect to N for all the twelve months. Therefore, a multiple linear regression was developed for estimating the radio refractivity (N) for the values of T and TUP. The prediction performance of the model was determined in terms of model estimation percentage error (e%). Afterwards, two meteorological datasets from published research articles [18, 20] were used to validate the model. The atmospheric refractivity (N) is determined as follows [14, 21, 22];

\[ N = \frac{77.6}{T} \left( p \right) + 4810 \left( \frac{e}{T} \right) \]  

(1)

Where

- T is the absolute temperature in Kelvin
- p is the atmospheric pressure in hPa
- e is the water vapour pressure

Furthermore, the atmospheric water vapour pressure can be determined using the relation:

\[ e = 6.112 \left( \frac{U}{100} \right) \exp \left( \frac{17.5(T)}{T + 240.4} \right) \]  

(2)

Where U is the relative humidity in % and T is the atmospheric temperature (Celsius). The statistical correlation between two parameters x and y is computed as follows;

\[ Correlation(x, y) = \frac{\sum_{i=1}^{n}(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^{n}(x_i - \bar{x})^2 \sum_{i=1}^{n}(y_i - \bar{y})^2}} \]  

(3)

Absolute Percentage error between the actual value \( X_a \) and the estimated value \( X_e \) is computed as ;

\[ Absolute \ Percentage \ error \ (%) = \left( \frac{|X_a - X_e|}{X_a} \right) \times 100 \]  

(4)

3. Results and Discussion

Two months (January and June) radiosonde meteorological data for Cross River for the year 2013 are given in Table 1 along with the computed radio refractivity and correlation values among the parameters, N, T, P, H and TUP. The The graph of relative humidity, U(%) and atmospheric pressure, P[hPa] versus refractivity gradient, N for the month of January 2013 is given in Figure 1 while Figure 2 shows the graph of temperature, T(C) and atmospheric pressure, P[hPa] versus refractivity gradient, N for the month of January 2013.

Table 2. June Radiosonde meteorological data for Cross River for the year 2013 along with the computed radio refractivity and correlation values among the parameters, N, T, P, H and TUP.
From the correlation values in Table 1 and Table 2, T and TUP have the highest correlation values in the two months. Similarly, for the T and TUP, high correlation values were also observed in all the twelve months considered. Hence, a multiple linear regression model was developed for estimating N from the values of T and TUP. There is a positive correlation between N and T, P and TUP which shows a direct proportional relationship between N and T, P and TUP. However, there is a negative correlation between N and U which shows inverse proportionality.

The model was developed using XURU online regression tool where the values of T is X1, TUP is X2 and N is Y. The dataset of T, TUP and N for the 12 months were pasted into the text box provided in Xuru Multiple Linear Regression (MLR) webpage and the model obtained from the Xuru MLR is given as:

\[ N = 2.38(T) + 0.000051[(T)(U)(P)] + 198.38 \]  

The model prediction performance in terms of absolute estimation percentage error (%) for the months of January and June 2013 are given in Table 3 and Table 4 respectively. According to Table 3 and Table 4, the maximum absolute estimation percentage error is 0.09 % for the month of January and 0.98 % for the month of February. Among the twelve months dataset used to develop the model, the highest value of maximum absolute estimation percentage error was 3.22 % and it was observed in the month of May, which is shown in Table 5.

4. Conclusions

The study examined the correlation among radio refractivity and the meteorological parameters, namely atmospheric temperature (T), atmospheric pressure (P) and relative humidity (H). The correlation values showed that there is a positive correlation between N and T, P and TUP (that is, the product of T, U and P) which means that N is directly proportional to T, P and TUP. However, there is a negative correlation between N and U which indicated inverse proportionality between N and U. In all, T and TUP showed highest correlation values for the model training datasets; as such the two parameters were used in the development of the linear regression model that can be used to estimate the radio refractivity for the available meteorological dataset. The model performance was validated with meteorological data extracted from published journal articles. The results showed that the model can estimate refractivity with a maximum prediction error of about ±3.35%. Furthermore, the model can be applied in computing refractivity in any climatic region.
