We investigate the topological character of lattice chiral Gaussian fermionic states in two dimensions possessing the simplest descriptions in terms of projected entangled-pair states (PEPS). They are ground states of two different kinds of Hamiltonians. The first one, $\mathcal{H}_G$, is local, frustration-free, and gapless. It can be interpreted as describing a quantum phase transition between different topological phases. The second one, $\mathcal{H}_t$, is gapped, and has hopping terms scaling as $1/r^3$ with the distance $r$. The gap is robust against local perturbations, which allows us to define a Chern number for the PEPS. As for (non-chiral) topological PEPS, the non-trivial topological properties can be traced down to the existence of a symmetry in the virtual modes that are used to build the state. Based on that symmetry, we construct string-like operators acting on the virtual modes that can be continuously deformed without changing the state. On the torus, the symmetry implies that the ground state space of the local parent Hamiltonian is two-fold degenerate. By adding a string wrapping around the torus one can change one of the ground states into the other. We use the special properties of PEPS to build the boundary theory and show how the symmetry results in the appearance of chiral modes, and a universal correction to the area law for the zero Rényi entropy.

I. INTRODUCTION

Topological states are quantum states of matter with intriguing properties. They include non-chiral states with topological order, such as the toric code and string net models, as well as chiral topological states. The latter have broken time-reversal symmetry, and possess non-vanishing topological invariants. They include celebrated examples like integer and fractional quantum Hall states, as well as Chern insulators and topological superconductors. They display chiral edge modes which are protected against local perturbations, and cannot be adiabatically connected to states with different values of the topological invariants.

Among others, a remarkable open problem in this field is to classify all topological phases; that is, the equivalence classes of local Hamiltonians that can be connected by a (symmetry preserving) gapped path. For their free fermion versions in arbitrary dimensions, a full classification has been already obtained. For interacting spins, this goal has only been achieved in one dimension, based on the fact that ground states of 1D gapped local Hamiltonians are efficiently represented by Matrix Product States (MPS). In dimensions higher than one, this problem remains open. Still, recent developments reveal that there exist deep intrinsic connections between quantum entanglement and topological states. For instance, topological order is reflected in the universal correction to the entanglement area law, also called topological entanglement entropy. A further proposal has been put forward by Li and Haldane, who suggested that the entanglement spectrum, that is, the eigenvalues of the reduced density operator of a subsystem, contains more valuable information than the topological entanglement entropy.

Projected Entangled Pair States (PEPS), higher dimensional generalizations of MPS, are a natural tool for investigating topological states. By construction, they contain the necessary amount of entanglement required by the entanglement area law. Furthermore, many known topological states, such as the toric code, resonating valence-bond states, and string nets, possess exact PEPS descriptions. Despite the lack of local order parameters, PEPS nevertheless provide a local description for topological states, with the global topological properties being encoded in a single PEPS tensor. For some of the above examples, the connection of topology and the PEPS tensor has been made precise as originating from a symmetry of the PEPS tensor (see also Ref. 19). This symmetry only affects the virtual particles used to build the PEPS, unlike the physical symmetries of the PEPS. It can be grown to arbitrary regions, and has several intriguing consequences: (i) it leads to the topological entanglement entropy; (ii) it gives rise to a universal part in the boundary Hamiltonian acting on the auxiliary particles at a virtual boundary, whose eigenvalues are related to the entanglement spectrum of the subsystem; (iii) it provides topological protection of the edge modes; (iv) it gives rise to string operators that provide a mapping between the different topological sectors; (v) it can also be used to build string operators for anyonic excitations and to determine the braiding statistics; (vi) it determines the ground state degeneracy of the parent Hamiltonian.

Chiral topological states are very different from the above mentioned topological states preserving time-reversal symmetry (known as nonchiral topological states), in that they necessarily have chiral gapless edge modes, which cannot be gapped out by weak perturbations due to the lack of a back-scattering channel. There have been doubts that PEPS can describe chiral topological states, until explicit examples with exact PEPS rep-
representations have been obtained very recently. These chiral PEPS examples are topological insulators and topological superconductors characterized by nonzero Chern numbers, albeit with correlations decaying as an inverse power law. In view of all that, very natural questions arise as whether these chiral topological PEPS fit into the general characterization scheme in terms of a symmetry of a single PEPS tensor, and whether useful information characterizing topological order manifests itself in the boundary Hamiltonian.

In this work, we answer these questions in an affirmative way for a family of topological superconductors similar to the one introduced in Ref. 23. Those are chiral Gaussian fermionic PEPS (GFPEPS), which are free fermionic tensor network states. We give general procedures to build the boundary Hamiltonians and analyze their properties (see also Ref. 24). We first show how to determine the boundary Hamiltonian for GFPEPS, and how the Chern number can be obtained by counting the number of chiral modes defined on the boundary Hamiltonian. Then we show that, as in the case of topological (non-chiral) PEPS, there exists a symmetry in the virtual modes that can be grown to any arbitrary region. We connect this symmetry to the chiral modes on the boundary, and show that it also gives rise to a universal correction to the area law in the zero Rényi entropy (although not in the von Neumann one), and to the boundary Hamiltonian.

Following Refs. 23 and 24, we also build two kinds of (parent) Hamiltonian for which the chiral GFPEPS are ground states, and analyze their properties. The first one, \( \mathcal{H}_g \), is Gaussian, local, frustration free, and gapless. In terms of that Hamiltonian, our states can be interpreted as being at the quantum phase transition between different phases characterized by different Chern numbers. That Hamiltonian is two-fold degenerate on the torus. We use the symmetry to build string operators that allow us to characterize the ground states of \( \mathcal{H}_g \), and that can be continuously deformed without changing the state. The second one, \( \mathcal{H}_b \), is also Gaussian, although gapped, and has a unique ground state on the torus. It is not local, possessing hopping terms decaying as \( 1/|r|^3 \) with the distance \(|r|\). We show that it is topologically stable to the addition of local perturbations. This allows us to consider the state as truly topological, and to define a Chern number which we find equals -1. We also compute the momentum polarization and show that it has the expected properties for a topological state. In addition, we provide a numerical example of a GFPEPS with two Majorana bonds (the number of Majorana bonds corresponds to twice the logarithm of the bond dimension in the normal PEPS language) and Chern number 2 having two symmetries of the above kind.

Given the variety of results obtained in this paper and the different techniques used to derive them, we start with a Section that gives an overview of all of them, and connects them to known properties of topological PEPS. The specific derivations and explicit statements and proofs are given in the following Sections. In Sec. III, a general framework for studying the boundary and edge theories of GFPEPS is developed. Their relation to the Chern number is established. In Sec. IV, we give different examples of GFPEPS, some of them topological and some of them not, in order to provide comparison between the two cases. In Sec. V we completely characterize all PEPS with one Majorana bond with topological character. It turns out that in this case the Chern number can only be 0 or ±1; for the latter case we derive necessary and sufficient criteria. In Sec. VI we prove a necessary and sufficient condition on the symmetry that a PEPS tensor has to possess in order to give rise to a chiral edge state for one Majorana bond, and show how those symmetries can be grown to larger regions and to build string-like operators.

II. Definitions and Results

This Section gives an overview of the main results of this paper. It also reviews in a self-contained way the basic ingredients that are required to derive the results, and to interpret them. It is divided in four subsections. The first one contains the definition of GFPEPS, which are the basic objects in our study. It also contains two Hamiltonians for which they are the ground state. The first one is gapped, has power-law hopping terms, and is the one that appears more naturally in the context of topological insulators and superconductors. The second one follows from the PEPS formalism, is gapless, and has a degenerate ground state. In the second subsection we present a simple family of GFPEPS, similar to the one introduced in Ref. 23, which we will extensively use to illustrate our findings. The third one contains the construction of boundary and edge theories for GFPEPS, which we explicitly use for the simple family. In the last subsection, we make a connection between the behavior observed for this family, and the one that is known for topological (non-chiral) PEPS (Ref. 16). In particular, we show that one can understand it in terms of string operators acting on the so-called virtual particles, which can be moved and deformed without changing the state.

Throughout this Section we will concentrate on the simplest GFPEPS – those which have the smallest possible bond dimension (which will correspond to one Majorana bond, see below). This will allow us to simplify the description and formulas. However, all the constructions given here can be easily generalized to larger bond dimensions, and this will be done in the following Sections. Some of the results, however, explicitly apply to one Majorana bond, so that we will specialize to that case in the following Sections too.
We consider a square $N_v \times N_h$ lattice of a single fermionic mode per site, with annihilation operators $a_j$, where $j$ is a vector denoting the lattice site. We will consider a state, $\Phi$, of a particular form, and Hamiltonians for which it is the ground state.

1. Gaussian Fermionic PEPS

We revise here the GFPEPS introduced in Ref. 25. We will first show how a GFPEPS, $\Phi$, of the fermionic modes is constructed (see Fig. 1).

The basic object in this construction is a fiducial state, $\Psi_1$, of one fermionic (physical) mode, and four additional (virtual) Majorana modes, all of them at site $j$ (Fig 1a).

The corresponding mode operators, $c_{j,L}, c_{j,R}, c_{j,U}, c_{j,D}$, and $c_{j,D}$ (L, R, U, and D, stand for left, right, up and down, respectively), fulfill standard anticommutation relations, $\{c_{j,\alpha}, c_{j,\beta}\} = 2\delta_{j,\alpha}\delta_{\alpha,\beta}$, are Hermitian and anticommute with the other fermionic operators. The state $\Psi_1$ is arbitrary, except for the fact that it must be Gaussian and have a well defined parity. This means that it can be written as

$$|\Psi_1\rangle_j = e^{\mathcal{H}_j}|\Omega\rangle,$$

where $\mathcal{H}_j$ is a quadratic operator in all the mode operators, and the $\Omega$ denotes the vacuum of the virtual and physical modes. One can easily parametrize $\mathcal{H}_j$, and thus $\Psi_1$, but this will not be necessary here, since we will make use of the fact that the state is Gaussian, for which a more appropriate parametrization exists.

The state of the physical fermions, $\Phi$, can be obtained by concatenating all the $\Psi_1$ at different sites in the same way we explain now and is illustrated in Fig. 1. First, take two consecutive lattice sites in the same column, $j$ and $n$, and project the up virtual mode of the first and the down of the latter onto a particular state, i.e.

$$|\Psi_2\rangle_{jn} = \omega_{jn} e^{\mathcal{H}_j + \mathcal{H}_n}|\Omega\rangle,$$

(see Fig 1b). Here $\omega_{jn} = \frac{1}{2}(1 + ic_{j,D}c_{n,U})$, which ensures that $c_{U}$ and $c_{D}$ are maximally entangled (forming a pure fermionic state). Since the modes that we project on are in a well defined state after the projection, we can omit them in the following. In order to simplify the notation, we will denote by $\langle \omega_{jn}|\Psi\rangle$ the state obtained by applying $\omega_{jn}$ and discarding the corresponding modes, and we will say that we have projected onto $\omega_{jn}$. We will also omit the indices representing the lattice sites whenever this does not lead to confusion.

We proceed in the same way, concatenating all the sites corresponding to a column by projecting out the consecutive up and down virtual modes onto the state defined by $\omega_{jn}$. The resulting state is $\Psi_{N_v}$, since we have $N_v$ sites in a column (see Fig 1c). This state contains $N_v$ physical fermionic modes, as well as $2N_v + 2$ virtual Majorana modes, $N_v$ on the left, $N_v$ on the right, one up and one down. Since we will consider here periodic boundary conditions along the vertical direction, we also project out the up and down virtual modes, obtaining $\Phi_1$, a state that corresponds to one column (and thus the subindex). Such a state contains $N_v$ physical fermionic modes, as well as $2N_v$ virtual Majorana modes (see Fig 1d). By construction, the state is translationally invariant along the vertical direction.

In order to obtain the state on the lattice, we have to follow a similar procedure in the horizontal direction (see Fig 1e). For that, we take the states of two consecutive columns, and project each of the right virtual modes (at site $n$) of the other onto $\omega_{jn} = \frac{1}{2}(1 + ic_{j,R}c_{n,L})$. The resulting state, $\Phi_2$, contains $2N_v$ physical fermionic modes, as well as $2N_v$ virtual Majorana modes. We continue...
In order to obtain a translationally invariant state in the horizontal direction too, we have to project each remaining virtual pair of modes on the left and the right onto the state defined by $\omega_{jn}^\prime$. In this case, we will say that we have a state, $\Phi$, on the torus. Otherwise, we can project the virtual modes on the left and the right onto some other state. If we took a product state (of left and right virtual modes) that is translationally invariant in vertical direction itself, we will still keep that property in the vertical direction and the state $\Phi$ will be defined on a cylinder. A subtle point is that, when we perform this last projection in order to generate the physical state $\Phi$, the result may vanish. This happens, for instance, in some of the examples considered in this paper in the torus case. There, we will have to introduce a string operator in the virtual modes for those particular sizes of our system.

The state $\Phi$ on the torus is fully characterized by the fiducial state $\Psi_1$ (and therefore by $\mathcal{H}$), since the construction is carried out by concatenating them with a specific procedure. For the cylinder, $\Phi$ also depends on the states we choose to close the virtual boundaries. From now on we will work on the torus, unless explicitly stated otherwise.

Since the fiducial state $\Psi_1$ is Gaussian and our construction keeps the Gaussian nature, all the states defined above will be Gaussian. For that reason, instead of expressing $\Psi$ and $\Phi$ in the Hilbert space on which the mode operators act, we characterize them in terms of their covariance matrices (CMs). In order to do so, we write each physical fermionic mode operator in terms of two Majorana operators,

$$a_j = (c_{2j-1} - ie_{2j})/2,$$

fulfilling the corresponding anticommutation relations. For a (generally mixed) Gaussian state $\rho$ in a set of Majorana modes, $c_i$, the CM, $\gamma$, is defined through

$$\gamma_{l,m} = \frac{i}{2} \text{tr}(\rho(c_l,c_m)).$$

This is a real antisymmetric matrix, fulfilling $\gamma^\top \gamma \leq \mathbb{1}$, where $\mathbb{1}$ is the identity matrix. The equality $(\gamma^2 = -\mathbb{1})$ is reached iff the state $\rho$ is pure. Thus, the original state $\Psi_1$ will have a CM with four blocks,

$$\gamma_1 = \begin{pmatrix} A & B \\ -B^\top & D \end{pmatrix}$$

where $A, D$ are $2 \times 2$ and $4 \times 4$ antisymmetric matrices, respectively, $B$ is a $2 \times 4$ matrix, and they are constrained by $\gamma_1^2 = -\mathbb{1}$ (since the state $\Psi_1$ is pure). Hence, the state $\Phi$ is completely characterized by those matrices. Concatenating states as explained above can be easily done in terms of the CMs (see Ref. 25 and Sec. 11A below).

If we consider the indices $l$ (and $m$) in Eq. (3) as joint indices of the site coordinates $r = (x, y)$ (and $r'$) and the index of the two Majorana modes located at site $r$ ($r'$), the $2 \times 2$ block of $\gamma$ of a GFPEPS for given sites $r$ and $r'$ fulfills

$$\gamma_{r,r'} = \gamma(r-r'),$$

since the construction of the GFPEPS is translationally invariant. Thus, it is convenient to carry out a discrete Fourier transform on $\gamma$. The result is, as outlined in Ref. 25 a block-diagonal matrix with blocks labelled by the momentum vector $k = (k_x, k_y)$. Due to the purity of the state, they are of the form

$$G(k) = \begin{pmatrix} \hat{d}_i(k) & d_i(k)+id_i(k) \\ -\hat{d}_i(k)+id_i(k) & -\hat{d}_i(k) \end{pmatrix}$$

with $\hat{d}_i(k) \in \mathbb{R}$ and $|\hat{d}(k)| = 1$.

The above construction can be trivially extended to more general GFPEPS, where there are $4\chi$ virtual Majorana modes and $f$ fermions per site. In Sec. III we will show how to carry out such a construction for that general case. The case considered in this Section, $\chi = 1$, is much simpler to describe and already possesses all the ingredients to give rise to topological chiral states.

2. Parent Hamiltonians

One can easily construct Hamiltonians for which $\Phi$ is the ground state. For that, we can follow two different approaches. The first one takes advantage of the fact that $\Phi$ is a Gaussian state, whereas the second uses that it is a PEPS.

Our first Hamiltonian is the “flat band” Hamiltonian

$$\mathcal{H}_{fb} = -\frac{i}{4} \sum_{l,m} \gamma_{l,m} e_l e_m$$

where $\gamma$ is the CM of the state $\Phi$, and $e$ are the Majorana modes built out of the physical fermionic modes. Since $\Phi$ is pure, $\gamma^2 = -\mathbb{1}$ and thus it has eigenvalues $\pm i$. Hence, $\mathcal{H}_{fb}$ contains two bands separated by a bandgap of magnitude 2, which are flat. As $\gamma$ is antisymmetric, there exists an orthogonal matrix $O$ such that $O \gamma O$ is block diagonal. Using this, one can easily convince oneself that $\Phi$ is the unique ground state of $\mathcal{H}_{fb}$. Note also that the Hamiltonian $\mathcal{H}_{fb}$ will not be local in general, since $\gamma_{l,m} \neq 0$ for all $l, m$. We also remark that for general $\gamma$ the single particle spectrum of a Hamiltonian of the form (8) is given by the eigenvalues of $-i\gamma$.

We transform Eq. (8) to reciprocal space and write it in terms of the Fourier transformed Majorana modes

$$e_{k,a} = \frac{1}{\sqrt{N_h^2 N_v}} \sum_r e_{r,a} e^{i k \cdot r}$$

Adding columns in the same way, until we obtain $\Phi_{N_h}$, containing $N_v \times N_h$ physical fermionic modes and $2N_v$ virtual Majorana ones (see Fig. 11).
(with \((r, \alpha)\) corresponding to the joint index \(l\) above), so that it takes the form

\[
H_{fb} = -\frac{1}{4} \sum_{k} \sum_{\alpha,\beta=1}^{2} G_{\alpha,\beta}(k) e_{k,\alpha} e_{k,\beta},
\]

where \(G_{\alpha,\beta}(k)\) is given in Eq. \(7\).

The second Hamiltonian can be constructed by invoking the general theory of PEPS (see, e.g., Ref. \(16\)). We can always find a local, positive operator, \(h \geq 0\), acting on a sufficiently large plaquette, that annihilates our state, i.e. \(h_j \Phi = 0\). Here \(j\) denotes the position of the plaquette. In the case of a GFPEPS, \(h_j\) can be chosen to be local. Furthermore, since the state is translationally invariant, we can take

\[
H_\Omega = \sum_j h_j.
\]

Now, this Hamiltonian is local (i.e., a sum of terms acting on finite regions, the plaquettes), frustration free (thus the subscript), and it is clear that \(\Phi\) is a ground state.

For the topological states considered later on, we will see that \(H_{fb}\) is intimately connected to the chiral properties at the edges, as it is well known for topological insulators and superconductors. The other one, \(H_\Omega\) will share other topological properties that makes it akin to Kitaev’s toric code and its generalizations.

**B. A family of topological superconductors**

1. Parameterization of the GFPEPS

Now, we review a family of chiral topological GFPEPS similar to that introduced in Ref. \(23\), which is characterized by a parameter, \(\lambda \in [0, 1]\). The fiducial state \(\Psi_1\) is given by

\[
|\Psi_1\rangle = \left(\sqrt{1-\lambda} \mathbb{1} + \sqrt{\lambda} a^\dagger b^\dagger\right) |\Omega\rangle.
\]

Here, \(b\) is an annihilation operator acting on the virtual modes as follows

\[
b = \frac{1}{\sqrt{2}} (h + v)
\]

where

\[
h = \frac{c_L - ic_R}{2} e^{\frac{i \pi}{4}} \text{ and } v = \frac{c_U - ic_D}{2}.
\]

The corresponding CM \(\gamma_1\) [Eq. \(5\)] is

\[
A = \begin{pmatrix} 0 & 1 - 2\lambda \\ -1 + 2\lambda & 0 \end{pmatrix},
B = \sqrt{\lambda - \lambda^2} \begin{pmatrix} 1 & -1 \\ -1 & 0 \end{pmatrix} - \sqrt{\frac{1}{2}},
D = \begin{pmatrix} 0 & 1 - \lambda & -\frac{\lambda}{\sqrt{2}} & -\frac{\lambda}{\sqrt{2}} \\ -1 + \lambda & 0 & \frac{\lambda}{\sqrt{2}} & \frac{\lambda}{\sqrt{2}} \\ \frac{\lambda}{\sqrt{2}} & \frac{\lambda}{\sqrt{2}} & -1 + \lambda & 0 \end{pmatrix}.
\]

We have sorted the Majorana mode operators as \(e_1, e_2, e_L, e_R, c_U, c_D\).

Later on we will consider other states, topological or not, to illustrate the properties of the boundary theories.

However, the family of states given here will be a central object of our analysis, since it already possesses all the basic ingredients. As it is evident from the definition, the fiducial state \(\Psi_1\) in Eq. \(12\) is an entangled state between the physical and one virtual mode, except for \(\lambda = 0, 1\), whereas for \(\lambda = 1/2\) it is maximally entangled. It has certain symmetries, which will be of utmost importance to understand the topological features of the state \(\Phi\) it generates. Explicitly,

\[
\begin{align}
(\sqrt{\lambda} a^\dagger - \sqrt{1 - \lambda} b^\dagger) |\Psi_1\rangle = 0, \\
(\sqrt{1 - \lambda} a + \sqrt{\lambda} b^\dagger) |\Psi_1\rangle = 0,
\end{align}
\]

with

\[
d_1 = \frac{1}{\sqrt{2}} (-h + v).
\]

The operators \(a, b,\) and \(d_1\) define three fermionic modes (one physical, and three virtual). Equations \(10\) just reflect the fact that for a Gaussian state the physical mode can be entangled at most to one virtual mode, since we can always find a basis in which one virtual mode is disentangled. The latter is precisely the one annihilated by \(d_1\). In fact, \(10\) completely defines the state \(\Psi_1\).

2. Algebraic decay of correlations

The correlation functions of the PEPS defined via Eq. \(12\) decay algebraically, see Ref. \(23\) and Fig. \(2\). This is most easily understood by considering the Fourier transform \(7\). All \(d_i(k)\) are continuous for all \(k\). However, the \(d_i(k)\) have a non-analyticity at \(k = (0, 0)\), where the first derivatives of \(d_x\) and \(d_y\) are discontinuous. For instance, for \(\lambda = 1/2\) in the example of Eq. \(12\), one
obtains
\[
\hat{d}_x(k) = -\frac{2\sin(k_x)(1 - \cos(k_y))}{3 - 2\cos(k_x) - 2\cos(k_y) + \cos(k_x)\cos(k_y)},
\]  
(18)
\[
\hat{d}_y(k) = \frac{2\sin(k_y)(1 - \cos(k_x))}{3 - 2\cos(k_x) - 2\cos(k_y) + \cos(k_x)\cos(k_y)},
\]  
(19)
\[
\hat{d}_z(k) = \frac{1 - 2\cos(k_x) - 2\cos(k_y) + 3\cos(k_x)\cos(k_y)}{3 - 2\cos(k_x) - 2\cos(k_y) + \cos(k_x)\cos(k_y)}.
\]  
(20)

At \(k = (0, 0)\) both the numerators and the common denominator are zero. In Appendix A we show that due to this non-analyticity, correlations in real space decay like the inverse of the distance cubed (up to possible logarithmic corrections).

3. Frustration free Hamiltonian: fragility

The frustration free parent Hamiltonian for this model is obtained by explicitly calculating the state \(\Psi_{2,2}\) obtained when four \(\Psi_1\) on a \(2 \times 2\) plaquette are concatenated without closing the boundaries in horizontal or vertical direction. Thereafter, one calculates the fermionic operator \(a_{\Box}\), acting only on the physical level, which annihilates \(\Psi_{2,2}\, a_{\Box}^\dagger |\Psi_{2,2}\rangle = 0\) (it turns out that exactly one such operator exists for any \(\lambda \in (0, 1)\)). This can be done conveniently in the CM formalism. The parent Hamiltonian, \(\mathcal{H}_\text{ff}\), can then be obtained by setting

\[
h_j(\lambda) \propto a_{\Box,j}^\dagger(\lambda) a_{\Box,j}(\lambda)
\]  
(21)
in Eq. (11). For \(\lambda = 1/2\), for instance, we have

\[
a_{\Box} = e_{a,1,1}(2 + i) + e_{b,1,1} - e_{a,1,2}(1 + 2i) + ie_{b,1,2} - e_{a,2,1} + e_{b,2,1}(-2 + i) + ie_{a,2,2} + e_{b,2,2}(1 - 2i),
\]  
(22)

where \(e_{a,x,y}\) denotes the first physical Majorana mode located at the site with coordinates \((x, y)\) and \(e_{b,x,y}\) the second one. The single-particle spectrum for that case is displayed in Fig. 3. Note that there is a band-touching point at \((k = (0, 0))\, and thus this Hamiltonian is gapless and has a continuous many-body spectrum. That is, it is exactly two-fold degenerate for finite systems, and in the thermodynamic limit it possesses a continuous spectrum right on top of the ground state.

The frustration free Hamiltonian \(\mathcal{H}_\text{ff}\) does not have a protected chiral edge mode, as it is gapless in the bulk: Let us add a translationally invariant perturbation [with variable GFPEPS parameter \(\lambda \in (0, 1)\)],

\[
\mathcal{H}_\text{ff}(\lambda, \mu_0, \nu_0) = H_\text{ff}(\lambda) - \frac{i}{\pi} \sum_{x,y} \left[ \mu_0 e_{a,x,y} e_{b,x,y} + \nu_0 (e_{a,x+1,y} e_{b,x,y} - e_{a,x,y} e_{b,x+1,y}) \right]
\]  
(23)

where \(\mu_0, \nu_0 \in \mathbb{R}\). Note that only \(\mu_0 = \nu_0 = 0\) corresponds to a GFPEPS ground state. After carrying out a Fourier transform, the Hamiltonian can be brought into the form

\[
\mathcal{H}_\text{ff}(\lambda, \mu_0, \nu_0) = \sum_{i=x,y,z} \sum_k d_i^k(a_k^i, a_{-k}^i) \sigma_i \left( \frac{a_k^i}{a_{-k}^i} \right)
\]  
(24)
with σ_i the Pauli matrices, the Chern number can be calculated via

\[ C = \frac{1}{4\pi} \int_{-\pi}^{\pi} \int_{-\pi}^{\pi} \hat{d}'(k) \cdot \left( \frac{\partial \hat{d}'(k)}{\partial k_x} \times \frac{\partial \hat{d}'(k)}{\partial k_y} \right) dk_x dk_y \]  

(25)

with \( \hat{d}'(k) = \frac{\partial \hat{d}(k)}{\partial k} \). Depending on the signs of the parameters \( \mu_0 \) and \( \nu_0 \), the Hamiltonian can be driven by infinitesimally small perturbations to gapped phases with Chern number \( C = 0 \) (trivial), \( C = -1 \) or \( C = -2 \) as shown in Fig. 3. This phase diagram does not depend on the parameter \( \lambda \) as long as \( |\mu_0| \) and \( |\nu_0| \) are sufficiently small. Hence, with respect to the frustration free Hamiltonian, the states defined by Eq. (12) describe critical points in the transition between different topological phases with Chern numbers \( C = -2 \) and \( C = -1 \) and a topologically trivial phase \( (C = 0) \).

We conclude that the frustration free Hamiltonian is gapless and thus not topologically protected. Instead, it is at the critical point between free fermionic topological phases with different Chern numbers.

4. Flat band Hamiltonian: robustness

Let us now consider the stability of the flat band Hamiltonian \( \mathcal{H}_b \) against perturbations. First, we will show analytically that the Hamiltonian is robust even against long-ranged translationally invariant perturbations; and second, we will demonstrate numerically the stability against local disorder. This shows that the Hamiltonian is topologically protected and its Chern number is therefore a meaningful quantity.

Let us first consider translationally invariant perturbations where we assume that the perturbation decays faster than \( 1/r^3 \) in real space (with \( |r| \) the distance). Then, it can be shown (see, e.g., Ref. 34 Proposition 3.2.12) that the perturbation \( \mathcal{H} \) is differentiable in Fourier space, and thus, the perturbed flat band Hamiltonian \( \tilde{\mathcal{H}} = \mathcal{H}_b + \epsilon \mathcal{H} \) is differentiable as well. Moreover, since the Fourier components of \( \mathcal{H} \) are uniformly bounded, the gap of \( \tilde{\mathcal{H}} \) stays open for sufficiently small \( \epsilon \). Thus, the bands of \( \mathcal{H}_b \) are a smooth function of \( \epsilon \), and thus, the Chern number cannot change under sufficiently small perturbations.

Let us now turn towards the stability of \( \mathcal{H}_b \) against random disorder, which we have verified numerically. To this end, we randomly added local disorder terms \( \sum_j \mu_j a_j a_j \ (\mu_j \in [-1,1]) \) to the flat band Hamiltonian for \( \lambda = 1/2 \) defined on an \( N_v \times N_t \) torus \( (N_b = N_v) \) as a function of its length \( N_v \). In Fig. 4, we plot the energy gap obtained for 225 random realizations for each system size \( N_v \). As can be gathered from the figure, its gap stays non-vanishing in the thermodynamic limit, indicating that it is topologically protected against disorder.

To summarize, the gap of the flat band Hamiltonian \( \mathcal{H}_b \) is topologically protected against the addition of on-site disorder and (small) translationally invariant perturbations whose hoppings decay faster than the inverse of the distance cubed. Its Chern number is \(-1\).

C. Boundary and Edge Theories

In Ref. 35 a formalism was introduced for spin PEPS to map the state in some region \( \mathcal{R} \) to its boundary. This bulk-boundary correspondence associates to each PEPS a boundary Hamiltonian, \( \mathcal{H}_b \), that acts on the virtual particles. The Hamiltonian faithfully reflects the properties of the original PEPS. In particular, for the toric code,
FIG. 6. Left: The state obtained after cutting out $N$ columns (region $R$) from a translationally invariant GFPEPS is still translationally invariant in the vertical direction. Hence, it can be understood as being defined on a cylinder. The Majorana modes on the left and the right boundary (small blue balls) remain unpaired. Right: Illustration of string operators. Those are defined as operators acting on the virtual Majorana modes lying on a closed string (such as the blue, red and green examples). The projection onto the final physical state $\Phi$ is carried out after applying one or more of those string operators.

or the resonating valence-bond states, that boundary Hamiltonian features their topological character. In this Section we review that theory for GFPEPS and show how one can determine $H_b$ for GFPEPS.

Chiral topological insulators and superconductors, on the other hand, are characterized by the presence of chiral edge modes, featuring robustness against certain bulk perturbations. Here, we also analyze how those features are reflected in $H_b$, as well as the relation of that Hamiltonian with that found for the toric code.

1. Boundary Theories

Given the GFPEPS $\Phi$, let us take a region $R$ of the lattice, trace all the degrees of freedom of the complementary region, $\overline{R}$, and denote by $\rho_R$ the resulting mixed state. As it was shown in Ref. 25, $\rho_R$ can be isometrically mapped onto a state of the virtual particles (or modes) that are at the boundary of the region $R$. That is, there exists an isometry $\mathbb{V}_R$, such that $\rho_R = \mathbb{V}_R \sigma_R \mathbb{V}_R^\dagger$, where $\sigma_R$ is a mixed state defined on those virtual modes.

Here we will take as region $R$ a cylinder with $N$ columns, see Fig. 6. There we have drawn the (red) physical fermions, as well as the (blue) virtual Majorana modes, as they appear in the construction explained above (Fig. 7).

The state $\sigma_R$ is Gaussian and is thus also characterized by a CM, which we will denote by $\Sigma_N$. In Sec. III we will show how to determine it in terms of $\gamma_1$. Here, we just quote the results. We can write

$$\sigma_R = \frac{1}{Z_N} e^{-\mathcal{H}_N^b},$$

where

$$\mathcal{H}_N^b = -\frac{i}{4} \sum_{j,k} (H_N^b)_{j,k} c_j^\dagger c_k,$$ (27)

is the so-called boundary Hamiltonian, with $c_j$ the Majorana operators acting on the left and right boundaries, and $H_N^b$ a $2N_v \times 2N_v$, antisymmetric matrix, given by

$$H_N^b = 2 \arctan(\Sigma_N).$$ (28)

The spectrum of $H_N^b$ coincides with the so-called entanglement spectrum. Here we will be interested in the corresponding single-particle spectrum, i.e. that of $H_N^b$.

Since $H_N^b$ is translationally invariant in the vertical direction, we can easily diagonalize it by using Fourier transformed Majorana modes. It is convenient to define

$$\hat{c}_y = \frac{1}{\sqrt{N_b}} \sum_{y=1}^{N_b} e^{i k_y y} c_y,$$ (29)

separately for the left and right virtual modes, so that $H_N^b$ displays a simple form in their terms. Here, the quasi-momentum is $k_y = 2\pi n / N_v$, with $n = -N_v/2 + 1, \ldots, N_v/2$. Up to a factor of two, the operators $\hat{c}_y^\dagger = \hat{c}_{-k_y}$ fulfill canonical commutation relations for fermionic operators, $\{\hat{c}_y, \hat{c}_y^\dagger\} = 2 \delta_{k_y, k'_y}$, for $k_y \neq 0, \pi$. For $k_y = 0, \pi$, they are Majorana operators (i.e., $\hat{c}_0^\dagger = \hat{c}_0$, and $\hat{c}_\pi^\dagger = \hat{c}_\pi$). This latter fact is crucial to understand the topological properties of the original state $\Phi$, as we will discuss in Sec. IV.

The single-particle spectrum (dispersion relation, since we have translational invariance) will be labeled by $k_y$. For the GFPEPS determined by Eq. (12) for $\lambda \in (0, 1)$ we will show that in the limit $N \to \infty$ one can write

$$H_N^b = \bigoplus_{k_y \neq 0, \pi} \left( \hat{H}_N^L(k_y) \oplus \hat{H}_N^R(k_y) \right) \oplus \hat{H}_N^{LR}(0) \oplus \hat{H}_N^{LR}(\pi)$$ (30)

where $\hat{H}_N^L(k_y)$ and $\hat{H}_N^R(k_y)$ correspond to virtual fermionic modes on the left and right, respectively, which are decorrelated from each other. For $k_y = 0$ and $k_y = \pi$, however, there is a single unpaired Majorana mode in each boundary. For the above family of chiral GFPEPS, the $k_y = 0$ Majorana modes pair up, giving rise to an entangled state between the left and the right boundaries, which is why we obtain the structure of Eq. (30) for the single-particle boundary Hamiltonian.

The Chern number, $C$ (up to a sign), is given by the number of right-movers minus the number of left-movers on one of the boundaries. For the simple case considered in this Section, with one Majorana bond, $|C| = 0, 1$. For GFPEPS with more Majorana bonds, one can build the boundary Hamiltonian in the same fashion, as we will show in the next Section. In that case, the Chern number is determined ditto, but it may be larger than one.

In Fig. 7 we plot the single-particle dispersion relation of the right boundary as a function of $k_y$, for the state generated by (12) for different values of $\lambda$ and $N \to \infty$ (we will provide an analytical formula for that limit in Sec. IV. It displays chirality, and the Chern number is $-1$. The mode at $k_y = \pi$ has zero “energy”, indicating
that the state of the left and right Majorana modes with such a momentum are in a completely mixed state. If we construct a fermionic operator using those two modes, the boundary state \( \sigma_R \) at momentum \( \pi \) has infinite temperature, and thus is an equal mixture of zero and one occupation. If we do the same with the modes at \( k_y = 0 \), the opposite is true, namely they are in a pure state (the vacuum mode of the fermion mode built out of the two Majorana modes from the left and the right). Thus, as anticipated, the left and right boundaries are in an entangled state, which reflects the topological properties of the state. In Sec. III we will show that all the features displayed by this example are intimately related.

As a second example, we take a state that does not display any topological features. Its explicit form is given in Sec. IV.C. The dispersion relation for the right boundary is shown in Fig. 8. Since the energy band of the boundary Hamiltonian does not connect the valence and conduction bands, the Chern number is zero. Furthermore, both at \( k_y = 0, \pi \) the "energy" vanishes, showing that the left and right boundaries are unentangled.

In Sec. IV we present further examples: We give an example of a GFPEPS displaying \( C = 2 \). We also investigate the Chern insulator presented in Ref. 22, and the resulting Hamiltonian, which has as many degrees of freedom as there are virtual Majorana modes, is the edge Hamiltonian, \( \mathcal{H}_N^e \). We now write

\[
\mathcal{H}_N^e = -\frac{i}{4} \sum_{l,m} (H_N^e)_{l,m} c_l c_m, \tag{31}
\]

and in Sec. III.C we show that one obtains that \( H_N^e = \Sigma_N \). Thus, up to a scale transformation (cf. Eq. 28), we see that the edge Hamiltonian is nothing but the boundary Hamiltonian, whenever we take the flat-band Hamil-
tonian as the parent Hamiltonian of our GFPEPS. This agrees with the statement of Ref. [37] and indicates that our results on the boundary Hamiltonian can be translated to the edge Hamiltonian constructed in the outlined way.

D. Symmetries, degeneracy, and Topological Entropy

Here, we will first briefly review how the topological properties of PEPS in spin systems are reflected in the symmetries of the corresponding fiducial state $\Psi_1$. Then we will show that for the GFPEPS considered in previous subsections, a similar behavior is present.

1. Spins

For PEPS in spin systems, all the properties are encoded in the single tensor which is used to build the state. In the language used in this paper, this tensor is equivalent to $\Psi_1$, since it is given by its coefficients in a basis. In particular, for topological states like the double model, there exist operators $U_g$, where $g$ is an element of a group $G$ and $U_g$ a unitary representation of it, acting on the virtual particles which leave $\Psi_1$ invariant. Those operators can be concatenated to string operators defined on the virtual modes on the boundary, so that for any state appearing during the construction of the PEPS $\Phi$, there exist other operators fulfilling the same property. Those operators can be built starting out from $U_g$ in a systematic way. This implies that for any region $\mathcal{R}$, there exists operators $U_g$ acting on the virtual particles at the boundary, such that

$$U_g \sigma_{\mathcal{R}} = \sigma_{\mathcal{R}} U_g = \sigma_{\mathcal{R}}.$$  (32)

For double models the operators $U_g$ can be written as products of operators acting on each of the virtual particles of the boundary.

From Eq. (32) it follows that $\sigma_{\mathcal{R}}$ is supported on a proper subspace of the virtual system, that corresponding to the eigenvalue 1 of all $U_g$, i.e.,

$$\sigma_{\mathcal{R}} = \frac{1}{Z_N} e^{-\nu_N} \mathcal{P}.$$  (33)

Here $\mathcal{P}$ is a non-local operator which projects onto that subspace. This fact has two consequences: (i) the zero Rényi entropy (which is the logarithm of the dimension of that subspace) does not coincide with the logarithm of the dimension of the Hilbert space of the virtual particles on the boundary of $\mathcal{R}$; (ii) there is a non-local constraint on the boundary and edge Hamiltonian. Those two features are thus related to the topological character of the PEPS. Note that (i) may also imply in some cases that there is a correction to the area law, what is usually called the topological entropy. That is, the von Neumann entropy of $\sigma_{\mathcal{R}}$ scales like the number of virtual particles on the boundary of $\mathcal{R}$ minus a universal constant, which is directly related to the topological properties of the model under study. The property (ii) acts as a superselection rule in the boundary and edge theories, since any perturbation in the bulk will not change that subspace. Additionally, in the spin lattices studied in Ref. [36], $\mathcal{H}_N^b$ is local (contains hoppings that decay exponentially with the distance) whenever the frustration free parent Hamiltonian of the state $\Phi$ is gapped.

Another consequence of (32) is apparent if we take a PEPS defined on the torus. Then, we can attach different string operators $U_g$ and $U_g'$ around the two different cuts of the torus (see Fig. 6). This means that during the construction of the PEPS, we apply those operators to the virtual particles at the position where the strings appear before applying the projections $\omega$ and $\omega'$. Because of the symmetry, those string operators can be moved without changing the state. However, they cannot be discarded given the topology of the torus. The states for each pair of $U_g$ and $U_g'$ are ground states of the parent, frustration free Hamiltonian of the PEPS as well, and for some particular $g, g'$ they are linearly independent. Thus, that Hamiltonian is degenerate and in fact all its ground states can be generated by applying the string operators on circles around the torus. Furthermore, anyonic excitations can be understood as the extreme points of open strings, and the braiding properties related to the group $G$.

2. Fermionic systems

Now we show that an analogous phenomenon is present in our chiral topological models. That is, as PEPS, they also possess a symmetry in $\Psi_1$ which is inherited for larger regions, and that gives rise to properties (i) and (ii). Besides that, the parent Hamiltonian $\mathcal{H}_g$ is degenerate on the torus, and the different ground states can be obtained by attaching to the virtual modes string operators around the torus. The strings can be deformed, without changing the state. However, there are some differences, too. First of all, the von Neumann entropy of $\sigma_{\mathcal{R}}$ does not display a universal correction, which we attribute to the long-range properties of the parent Hamiltonian $\mathcal{H}_g$ of the state $\Phi$ (see Refs. [23] and [24]). For the same reason, the hoppings in $\mathcal{H}_N^b$ decay according to a power law. Furthermore, the ground-state subspace of the parent Hamiltonian, $\mathcal{H}_g$, is doubly degenerate on the torus, and some topologically inequivalent string configurations give rise to the same state.

Let us consider any region $\mathcal{R}$, and denote by $\Psi_{\mathcal{R}}$ the state obtained by projecting all the virtual modes within region $\mathcal{R}$ onto the state generated by $\psi_{\mathcal{R}}$, as they appear in the PEPS construction. We arrive at a state of the physical modes in $\mathcal{R}$ and the virtual ones sitting at the boundary of $\mathcal{R}$. For instance, if we take as $\mathcal{R}$ a cylinder with $N$ columns, the state $\Psi_{\mathcal{R}} = \Phi_N$ (see Fig. 6).
We can write
\[
\Phi = \langle \omega_{\partial R, \partial R} | \Psi_R, \Psi_R \rangle, \tag{34}
\]
where \(\omega_{\partial R, \partial R}\) projects out all the virtual modes at the boundaries of \(R\) and its complement \(R\).

If a contour \(C\) encloses a connected region \(R\), for chiral GFPEPS with one Majorana bond, there is a fermionic operator \(d_C\) such that
\[
d_C | \Psi_R \rangle = 0. \tag{35}
\]
For any contour, we will say that the state
\[
| \Phi_C \rangle = \langle \omega_{\partial R, \partial R} | d_C | \Psi_R, \Psi_R \rangle, \tag{36}
\]
is a GFPEPS with a string along the contour \(C\). In Sec. VI D we will show how this string operator can be deformed continuously for a chiral GFPEPS without changing the state we are building. However, if a contour wraps up around one of the sections of the torus, we cannot get rid of it by continuous deformations.

Let us denote by \(C_{h,v}\) contours wrapping the torus horizontally and vertically, respectively. We show in Sec. VI D that if we build the family of chiral GFPEPS starting out from \(\Psi_1\) according to Eq. (12), we obtain \(\Phi = 0\) after the last projection. However, the states obtained if we add a certain string along any of those contours coincide, \(\Phi_{C_{h,v}} \propto \Phi_{C_{h,v}}\), and in the following that is the state that we will consider. We also show that if we insert string operators along the two contours \(C_h\) and \(C_v\), the state \(\Phi_{C_h C_v}\) we obtain is orthogonal to the previous one, but it is also a ground state of \(H_H\).

The frustration free Hamiltonian has certainly very interesting properties, although we cannot determine them unambiguously given our results. It is not only at a quantum phase transition point between free fermionic (gapped) phases with Chern numbers \(C = 0, -1\) and \(-2\), but it furthermore carries features of states described by PEPS with long-range topological order: Its ground state manifold is obtained by inserting strings along the non-trivial loops of the torus. Hence, our results also allow to interpret the local parent Hamiltonian as being at the edge of a topologically ordered interacting phase.

The existence of the operators \(d_C\) in Eq. (35) for any simply connected region \(R\) has another important consequence. It follows that we can build a unitary operator \(U = 1 - 2d_0^*d_C\) such that Eq. (32) is fulfilled for the boundary operator. As a consequence, we also have Eq. (38) with \(P = 1 - d_0^*d_C\). Note that in our case \(G = \mathbb{Z}_2\) is represented by \(\{1, U\}\). Thus, we conclude that the properties of the previous paragraph (i) (topological correction to zero Rényi entropy) and (ii) (non-local constraint on boundary and edge Hamiltonian) are fulfilled as in the standard PEPS case. Note that if \(R\) lies on a cylinder as in Fig. 6, we can also give the interpretation that, as in the case of a Majorana chain, there are two Majorana modes at the boundaries building a fermionic mode in the (pure) vacuum state. As a consequence, we can write \(\sigma_\mathcal{R}\) for the cylinder as in Eq. (33), where \(P\) projects onto the subspace where that mode is in the vacuum.

In addition to the zero Rényi entropy \(S_0(N_v)\), we have also numerically computed the von Neumann entropy \(S_{\text{vN}}(N_v)\) for the example given in Eq. (12) for \(\lambda = 1/2\). Both are shown in Fig. 9 as a function of \(N_v\): While the zero Rényi entropy clearly shows a topological correction of \(\ln(2)\), similar to the toric code model, the von Neumann entropy does not exhibit such a correction. As we prove in Appendix B, this follows from the fact that \(S_{\text{vN}}(N_v)\) forms a discrete approximation to the integral over the modewise entropy, which is sufficiently smooth in \(k_\mu\) to ensure fast convergence. The same happens for all Rényi entropies \(S_\alpha\) except for \(\alpha = 0\). This is consistent with the result of, e.g., Ref. 33 (where, however, only non-chiral topological states have been considered).

In order to further investigate the topological properties of our model, we have also computed the so-called momentum polarization\(^{27}\) (see also Refs. 32, 40 and 41), which measures the topological spin and chiral central charge of an edge\(^{27}\). For a state \(|\varphi\rangle\) on a cylinder, it is defined as \(\mu(N_v) = \langle \varphi | T_L | \varphi \rangle\), where \(T_L\) is the translation operator on the left half of the cylinder. It can thus be rephrased in terms of the (many-body) entanglement spectrum \(\lambda_\alpha\) of the left half, which implies that in the framework of PEPS, it can be naturally evaluated on the virtual boundary between the two parts of the system. In particular, for GFPEPS it can be expressed as a function of the (single-particle) spectrum of the boundary Hamiltonian \(H_N^\mathcal{B}\), as shown in Fig. 11. In Ref. 27, it has been shown that (for systems with CFT edges) \(\mu(N_v) = \exp(-\alpha N_v - 2\pi i \tau/N_v + \ldots)\), with a non-
universal $\alpha$, and a universal $\tau$ which carries information about the topological properties of the system. In Appendix B we prove that for GFPEPS, $\mu(N_v)$ exactly follows the above behavior, and $\tau$ is indeed universal: Remarkably, it only depends on whether the boundary Hamiltonian exhibits a divergence, but not at all on its exact form. In particular, for our example, we analytically obtain a $\tau$ which corresponds to a chiral central charge of $c = 1/2$, independently of $\lambda$, in accordance with expectations.

Finally, an interesting behavior is also observed for the boundary Hamiltonian, Eq. (28), for $N \to \infty$. On the right boundary we perform the Fourier transform to position space $[H^R_{\infty}]_{n,m}$. Then, for $y \gg 1$, $[H^R_{\infty}]_{n,n+y} \propto \log(y)/y + O(1/y)$, see Appendix C. Thus, the decay is not exponential as it is the case for gapped phases in spins, but follows a power law. We plot the hopping amplitudes $||H^R_{\infty}||_{1,1+y}$ of the above chiral family for $\lambda = 1/2$ in Fig. 10.

III. DETAILED ANALYSIS

In this Section, we provide a detailed derivation of the boundary and edge theories for GFPEPS. We start in Sec. III A by formally introducing GFPEPS, and then provide the derivation of boundary theories (III B) and edge theories (III C) for GFPEPS.

A. GFPEPS

The construction of GFPEPS given in Sec. III A can be defined more generally for $f$ physical fermionic modes per site and $\chi$ Majorana bonds between them. We again start with an $N_v \times N_v$ lattice, now with $\chi$ left, right, up and down Majorana modes per site, $c_{j,L,\kappa}, c_{j,R,\kappa}, c_{j,U,\kappa}$ and $c_{j,D,\kappa}$ respectively, where $\kappa = 1, \ldots, \chi$ is the index of the Majorana bonds. At each site $j$ they are jointly with the physical modes in a Gaussian state as in Eq. (1). The procedure to construct the GFPEPS is the same, except that there are now $\chi$ virtual bonds between any two neighboring sites, i.e., here we have to set

$$
\omega_{jn} = \frac{1}{2\chi} \prod_{\kappa=1}^{\chi} (1 + ic_{j,D,\kappa}c_{n,U,\kappa}),
$$

(37a)

$$
\omega'_{jn} = \frac{1}{2\chi} \prod_{\kappa=1}^{\chi} (1 + ic_{j,R,\kappa}c_{n,L,\kappa}),
$$

(37b)

for the vertical and horizontal bonds, respectively. We will again denote by $\omega_{jn}$ ($\omega'_{jn}$) the map which applies $\omega_{jn}$ ($\omega'_{jn}$) and discards the corresponding virtual modes. For simplicity, in the following we will call the states generated by the operators (37) out of the vacuum maximally entangled states. The remaining procedure of how to concatenate them is the same as in Sec. III A, cf. also Fig. 1.

In this scenario the CM is likewise given by Eq. (5), just that the blocks $A$, $B$, and $D$ now have sizes $2f \times 2f$, $2f \times 4\chi$, and $4\chi \times 4\chi$, respectively. We are interested in how to determine the CMs of the different states $\Psi_{N_v}$, $\Phi_{N_v}$, and $\Phi$ involved in the construction of the GFPEPS. It is based on two operations (see Fig. 1): (i) building the state of $l + m$ modes out of two states of $l$ and $m$ modes, respectively, i.e., taking tensor products; (ii) projecting some of the modes onto some state (given by $\omega$ or $\omega'$). Apart from that, we will also extensively use in other parts of this paper: (iii) tracing out some modes.

In terms of the CM, those operations are performed as follows. (i) — joining two systems: the resulting CM is a $2 \times 2$ block diagonal matrix, where the two diagonal blocks are given by the CM of the state of the $l$ and $m$ modes, respectively. The operation (ii) — projecting out some of the modes, is slightly more elaborate. Let us consider an arbitrary state (pure or mixed) with CM $\gamma_1$ with blocks $A, B, D$ [as in Eq. (5)], and we want to project the last modes (corresponding to matrix $D$) onto some other state of CM $\omega$. The resulting CM is given by

$$
\gamma_1' = A + B(D + \omega^{-1})^{-1}B^T.
$$

(38)

Typically, we will have to project onto the states generated by (37). Their CM is very simple,

$$
\omega = \begin{pmatrix}
0 & -I \\
I & 0
\end{pmatrix}.
$$

(39)
which are collectively denoted by $\partial(R)$, the region $R$ of freedom are denoted by for the (inner) boundary of region $\bar{R}$.

After cutting the bonds as indicated in (a), the region $R$ has unpaired virtual indices at its boundary which are collectively denoted by $\partial R$. (c) The same is true for the (inner) boundary of region $\bar{R}$, whose virtual degrees of freedom are denoted by $\partial \bar{R}$.

Finally, in the case of operation (iii)—tracing out some of the modes, one simply has to take the corresponding subblock of the CM. This block is the CM of the reduced state. For instance, if one traces out the physical degrees of freedom of the state described by the CM \[\bar{\gamma}\] one obtains a (generally mixed) state defined on the virtual degrees of freedom with CM $D$. Conversely, one can also build the CM of a purification of a mixed state $D$, as

$$
\begin{pmatrix}
-D & \sqrt{1 + D^2} \\
-\sqrt{1 + D^2} & D
\end{pmatrix}
$$

Operations (i) and (ii) can be used to build the CM of the state $\Phi$ out of that of $\Psi_1$. In this Section we will extensively use all presented operations to construct the boundary and edge states and Hamiltonians.

B. Boundary Theories

1. Boundary Theories in GFPEPS

We will now show how to derive boundary theories in the framework of fermionic Gaussian states, by only using their description in terms of CMs rather than the full state. We consider a bipartition of the PEPS $\Phi$ into two regions $R$ and $\bar{R}$ (Fig. 11) and are interested in the reduced state $\rho_R = \text{tr}_{\bar{R}}(\rho(\Phi/\Phi))$. We proceed as follows. First, we consider the states where all virtual bonds within those regions have been projected out, leaving only virtual particles at the boundaries of those regions (which are denoted by $\partial R$ and $\partial \bar{R}$, respectively) unpaired. Hence, we are left with two states, which are defined on the physical degrees of freedom of these regions plus the virtual degrees of freedom of the respective boundaries (see Fig. 11b,c). We define their CMs as

$$
\Gamma = \begin{pmatrix} L & F \\ -F^T & G \end{pmatrix} \quad \text{and} \quad \tilde{\Gamma} = \begin{pmatrix} L & F \\ -F^T & G \end{pmatrix}
$$

respectively, where the first (second) block corresponds to the physical (virtual) degrees of freedom. The whole GFPEPS $\Phi$ could be obtained by pairwise projecting their virtual degrees of freedom on maximally entangled states, and thus, according to Eq. (38), its CM is

$$
\gamma = \begin{pmatrix} L & 0 \\ 0 & \tilde{L} \end{pmatrix} + \begin{pmatrix} F & 0 \\ 0 & \tilde{F} \end{pmatrix} \begin{pmatrix} G & \mathbb{1} \\ -\mathbb{1} & \tilde{G} \end{pmatrix}^{-1} \begin{pmatrix} F & 0 \\ 0 & \tilde{F} \end{pmatrix}^T.
$$

The CM of $\rho_R$ is given by the (1,1) block of Eq. (42), that is

$$
\gamma_R = L + F(G + \tilde{G}^{-1})^{-1}F^T.
$$

As explained in Sec. III C we are interested in a state $\sigma_{\partial R}$ defined on the virtual degrees of freedom located on $\partial R$, which is isometric to $\rho_R$. Naively, one could think that its CM is given by the (2,2) block of $\Gamma$, i.e., $G$, which corresponds to a reduced state acting on that boundary. However, this is not the case in general, since the state described by the CM $G$ is usually not isometric to $\rho_R$. As outlined in Ref. 35, $\sigma_{\partial R}$ is given by a symmetrized version which takes into account $\partial R$ and $\partial \bar{R}$. In fact, we can construct $\sigma_{\partial R}$ by first finding the appropriate purification of $\rho_R$, and then tracing the physical modes. We will carry out that task in two steps. First, we will conveniently rotate the basis of the physical Majorana modes in region $R$ and afterwards truncate the redundant degrees of freedom (projection). Both taken together correspond to the application of an isometry on $\rho_R$.

We start with an orthogonal basis change in the basis of physical Majorana modes $\{e_l\}$ in region $R$. The new ones are given by an orthogonal matrix $M$,

$$
e'_m = \sum_l M_{m,l} e_l.
$$

This obviously does not change the spectrum of $\rho_R$. By performing this basis change, the CM $\Gamma$ gets modified to

$$
\Gamma' = \begin{pmatrix} M & 0 \\ 0 & \mathbb{1} \end{pmatrix} \begin{pmatrix} L & F \\ -F^T & G \end{pmatrix} \begin{pmatrix} M^T & 0 \\ 0 & \mathbb{1} \end{pmatrix}.
$$
Note that this CM corresponds to a pure state, as Γ does. We choose \( M \) in such a way that \( \Gamma' \) decouples into a purification of the virtual state and a trivial part on the remaining physical level. This is always possible if the region \( R \) contains more degrees of freedom than \( \partial R \) and can be done practically by using a singular value decomposition of \( F \). Then,

\[
\Gamma' = \begin{pmatrix} Z & 0 & 0 \\ 0 & -G & \sqrt{I+G^2} \\ 0 & -\sqrt{I+G^2} & G \end{pmatrix},
\]

(45)

where \( Z \) is the CM of a pure state defined on the physical level and the remaining non-trivial part of \( \Gamma' \) corresponds to a purification of \( G \) (note that the first and second block correspond to the physical degrees of freedom and only the third block to the virtual ones). We discard the decoupled physical part and project the virtual degrees of freedom (together with those of region \( \bar{R} \), given by \( G \)) on the maximally entangled state. This yields the relevant part of Eq. (43), which is the CM of \( \sigma_R \)

\[
\Sigma_N = -G + \sqrt{G^2 + (G + G^{-1})^{-1}} \sqrt{I + G^2},
\]

(46)

which is defined on the modes at the boundary. (We denote it by \( \Sigma_N \), since \( R \) will be typically taken to lie on a cylinder, cf. Fig. 4 with \( N \) columns. However, Eq. (46) is true for any bipartition \( R, \bar{R} \).

In order to obtain the boundary Hamiltonian

\[
H^b_N = \frac{1}{2} \sum_{l,m} H^b_{N(l,m)} c_l c_m,
\]

which reproduces the entanglement spectrum, we can then use the relation

\[
H^b_N = 2 \arctan(\Sigma_N),
\]

(47)

Note that for \( G = G \), Eq. (46) yields a trivial entanglement spectrum, \( \Sigma_N = 0 \), while for \( G = -G \), one finds \( \Sigma_N = -2G(I - G^{-1})^{-1} \), which gives a factor of \( \frac{1}{2} \) in the entanglement temperature (i.e., the effective strength of \( H^b_N \)) with respect to \( G \),

\[
H^b_N = 4 \arctan(G),
\]

corresponding to the case \( \sigma_L = \sigma_R \) in Ref. [34].

A crucial point to observe in the result for the boundary theory is that \( \Sigma_N \) only depends on the CMs \( G \) and \( G \), which characterizes the reduced state of the virtual degrees of freedom at the boundaries of \( R \) and \( \bar{R} \). We can therefore trace the physical degrees of freedom from the beginning and only ever need to consider \( G \) and \( \bar{G} \).

While this observation is also true for general PEPS, it is particularly useful when working with GFPEPS in terms of CMs, as it allows us to completely neglect the physical part of the CM right from the beginning.

Let us finally briefly comment on the relation of the boundary theory as given by \( \Sigma_N \) to the construction of the boundary theory for general PEPS derived in Ref. [33]. There, the part of the PEPS which describes \( R \) (corresponding to the CM \( \Gamma \)) is interpreted as a linear map \( \chi^R \) from the boundary to the bulk degrees of freedom, which is then decomposed as \( \chi^R = \nu^R \rho^R \), with \( \nu^R \) an isometry and \( \rho^R = \nu^R \rho^R \), where \( \rho^R \) is the reduced density matrix of \( R \) on the virtual system (corresponding to \( G \)). This is exactly identical to the decomposition \( \chi^R = \gamma^R \rho^R \), in particular, \( M \) describes the isometry \( \nu^R \rho^R \), and the \((2+3,2+3)\) block of \( \Gamma' \) describes the map \( \nu \rightarrow \sqrt{\tau_R} \nu \sqrt{\tau_R} \) (realized by projecting the \((3,3)\) part onto \( \nu \)). Finally, \( \bar{G} \) describes the analogous state \( \tau_R \) obtained from the part \( \bar{R} \), and thus, \( \Sigma_N \) is exactly identical to the boundary theory \( \sqrt{\tau_R} \tau_R \sqrt{\tau_R} \) derived in Ref. [35].

2. Boundary Theories on the torus

We will focus now on the situation where the GFPEPS is placed on a square lattice on a long torus, where we take the length of the torus to infinity. The two regions \( R \) and \( \bar{R} \) are then obtained by cutting the torus into two halves, and are thus given by (identical) long cylinders with diameter \( N_y \) and length \( N \rightarrow \infty \), cf. Fig. 5. As we have seen, the central object in the description is the CM \( G \) at the boundary of region \( R \), \( \partial R \), obtained after tracing out the physical system (and correspondingly for \( \bar{R} \)). In the case of a cylinder, \( R \) is given by the left and right boundary of the cylinder together. In the following, we will show how to determine \( G \) given the CM \( \gamma_1 \) defining the GFPEPS, without having to construct the CM of the whole state \( \Phi_N \).

As we have seen in the preceding Subsection, the boundary theory is entirely determined by the CM of the virtual part of the initial state \( \Psi_1 \). We thus start by decomposing the CM of the virtual system of \( \Psi_1 \) into

\[
D = \begin{pmatrix} H & K \\ -K^\top & V \end{pmatrix}.
\]

(48)

Here, \( V \) corresponds to the vertical and \( H \) to the horizontal Majorana modes, respectively. We now concatenate one column of tensors, closing its vertical boundary, leaving us with a CM which describes the left and right virtual indices of the column (cf. Fig. [11]-d). This is done by employing Eq. (33) for the corresponding subblocks of \( V \) of each pair of (cyclically) consecutive states \( \Psi_1,j \) and \( \Psi_{1,k} \). Due to translational invariance, this is conveniently expressed in the Fourier basis (with \( k_y \) the quasi-momentum in \( y \)-direction): In this basis the \( D \)'s of one column form a block-diagonal matrix, while

\[
\hat{\omega}(k_y) = \begin{pmatrix} 0 & e^{i k_y} \mathbb{1}_\chi \\ -e^{-i k_y} \mathbb{1}_\chi & 0 \end{pmatrix}
\]

(\( \mathbb{1}_\chi \) denoting the \( \chi \times \chi \) identity matrix) since the \( \omega \)'s of one column form a circulant matrix with the two blocks coupling the “up” and “down” indices of adjacent \( V \)'s. In Fourier space, the CM describing the left and right virtual modes of one column is thus

\[
\hat{D}_1 = H + K (V + \hat{\omega}^{-1})^{-1} K^\top.
\]

(48)

(We use the hat to denote dependence on \( k_y \) in the following; the subscript \( N \) of \( D_N \) indicates the number of columns.) Taking advantage of the fact that the matrix
inverse can be written in terms of determinants, one immediately finds that each entry of \( \hat{D}_1 \) is a complex ratio of trigonometric polynomials (i.e., polynomials in \( e^{\pm ik_y} \)) with a degree bounded by the dimension of \( \hat{\omega} \), i.e., \( 2\chi \).

The matrix \( \hat{D}_1 \) consists itself of four blocks,

\[
\hat{D}_1 = \begin{pmatrix} \hat{R}_1 & \hat{S}_1 \\ -\hat{S}_1^\dagger & \hat{T}_1 \\ \end{pmatrix},
\]

(49)

corresponding to the left and right indices, respectively. Let us now see what happens if we contract two columns. We will consider the general case where the two columns can be different — for instance, each of them could have been derived by contracting some number of single columns \( \Phi_1 \); this will allow us to easily derive recursion relations. We thus have two columns described by

\[
\hat{D} = \begin{pmatrix} \hat{R} & \hat{S} \\ -\hat{S}^\dagger & \hat{T} \\ \end{pmatrix}
\]

and \( \hat{D}' = \begin{pmatrix} \hat{R}' & \hat{S}' \\ -\hat{S}'^\dagger & \hat{T}' \\ \end{pmatrix} \),

with a column of maximally entangled states connecting them: The CM of both blocks concatenated is then according to Eq. (38)

\[
\hat{D}'' = \begin{pmatrix} \hat{R} & 0 \\ 0 & \hat{T}' \\ \end{pmatrix} + \begin{pmatrix} -\hat{S} & 0 \\ 0 & \hat{T} \end{pmatrix} \begin{pmatrix} \hat{T} & 1 \\ -1 & \hat{T}' \end{pmatrix}^{-1} \begin{pmatrix} -\hat{S}^\dagger & 0 \\ 0 & \hat{S}^\dagger \end{pmatrix}.
\]

(50)

Using the Schur complement formula for the matrix inverse in the middle, this gives a recursion relation for the blocks \( \hat{R}, \hat{S}, \) and \( \hat{T} \), which serves several purposes. In particular, by choosing \( \hat{D} = \hat{D}' \), we can obtain an iteration formula for \( \hat{D}_n \) describing \( 2^n \) columns, which quickly converges towards the infinite cylinder limit \( \hat{D}_\infty \), thus being very useful for numerical study. Moreover, as we will see in Sec. IV in certain cases it can also be used to analyze the convergence of the transfer operator, or, by choosing \( \hat{D}' = \hat{D}'' \) and \( \hat{D} = \hat{D}_1 \), to determine the explicit form of the fixed point \( \hat{D}_\infty \).

Finally, given the fixed point \( \hat{D}_\infty \), as well as \( \hat{D}_\infty \) corresponding to the boundary \( \partial \mathcal{R} \), it is now straightforward to determine the boundary Hamiltonian using eqs. (46) and (28) for \( N \to \infty \). Note that in the particular case of a torus which we consider, \( \hat{D}_\infty \) can be obtained from \( \hat{D}_\infty \) by exchanging the blocks corresponding to the left and right boundary.

C. Edge theories

1. Derivation of edge theory

We will now turn our attention towards the edge Hamiltonian, which describes the effective low-energy physics obtained at an edge of the system.

As explained in Sec. III C the GFPEPS \( \Phi \) is the ground state of the flat band Hamiltonian \( \mathcal{H}_{fb} = -i \sum_{l,m} \gamma_{l,m} \mathcal{E}_{m} \), Eq. (8), where \( \gamma \) is the CM of the whole state \( \Phi \), Eq. (12). The restriction of \( \mathcal{H}_{fb} \) to a region \( \mathcal{R} \) of the system is then given by

\[
\mathcal{H}_\mathcal{R} = -i \sum_{l,m} \gamma_{l,m} e^{2\pi i m},
\]

(51)

where the sum now only runs over modes in \( \mathcal{R} \), and \( \gamma_{l,m} \) is determined by Eq. (13).

Let us now perform the basis transformation \( M \), Eq. (44): Following Eq. (43), the CM of \( \mathcal{R} \), \( \gamma_{\mathcal{R}} \), is then transformed to

\[
\gamma_{\mathcal{R}'} = \begin{pmatrix} Z & 0 \\ 0 & \Sigma_N \end{pmatrix},
\]

with \( \Sigma_N \) given by Eq. (16), and at the same time, \( \mathcal{H}_\mathcal{R} \) is transformed into an isomorphic Hamiltonian \( \mathcal{H}_\mathcal{R}' = -i \sum_{l,m} \gamma_{l,m} e^{2\pi i m} \). We thus see that the spectrum of \( \mathcal{H}_\mathcal{R}' \) (and thus of \( \mathcal{H}_\mathcal{R} \)) consists of two parts: First, the (1,1)-block of \( \gamma_{\mathcal{R}'} \) corresponds to bulk modes at energy \( \pm 1 \). Second, the (2,2) box \( \Sigma_N \) corresponds to modes at generally smaller energy, which are thus related to restricting \( \mathcal{H}_{fb} \) to region \( \mathcal{R} \); those modes are related to the boundary degrees of freedom via the purification in the (2+3,2+3) block of \( \Gamma' \), Eq. (45). We thus find that the edge Hamiltonian, i.e., the low-energy part of the truncated flat band Hamiltonian, is given by

\[
\mathcal{H}_N^e = \Sigma_N,
\]

(52)

with \( \mathcal{H}_N^e = -i \sum_{l,m} \gamma_{l,m} e^{2\pi i m} \), Eq. (61). Except for additional bulk modes with energy \( \pm 1 \), \( \mathcal{H}_N^e \) in fact exactly reproduces the spectrum of the truncated flat band Hamiltonian. The relation (52) allows us to transfer the results on the boundary theory \( \Sigma_N \) of GFPEPS one-to-one to their edge Hamiltonian \( \mathcal{H}_N^e \). Note that the resulting relation between entanglement spectrum and edge Hamiltonian, \( \mathcal{H}_N^e = 2 \arctan(H^{\infty}_N) \), corresponds to the one derived by Fidkowski\textsuperscript{32}.

The derivation of the edge Hamiltonian in this section is again identical to the edge Hamiltonian introduced for general PEPS in Ref. 22. Using the same notation as in the last paragraph of Sec. III B the edge Hamiltonian for general PEPS is obtained by projecting the physical Hamiltonian onto the boundary using the isometry \( V_e \). This projection is exactly accomplished by rotating with \( M \) and subsequently considering only the (2,2) block of \( \gamma_{\mathcal{R}'} \), and thus, the edge Hamiltonian obtained here is identical to the one of Ref. 22, with the bulk Hamiltonian taken to be the flat band Hamiltonian.

2. Localization of edge modes

In the case of a cylinder, on which we focus, the edge Hamiltonian \( H_N^e \) is supported on the auxiliary modes both on the left and the right edge (cf. Fig. 11). However, as we will show in the following, the edge Hamiltonian (as well as the boundary theory) on the two edges decouples for almost all \( k_y \), and moreover, the corresponding
physical edge modes are localized at the same edge as the virtual modes. An important consequence of that is that we can use the virtual edge Hamiltonian to compute the Chern number of the system, as it is known that the Chern number corresponds to the winding number of the edge modes localized at one of the edges of the system.\(^{14,15}\)

In order to answer both of these questions, we will first need to demonstrate some properties of the CM \(\Gamma \equiv \Gamma_N\), Eq. (41), which describes the GFPEPS \(\Phi_N\) (Fig. 11) on a cylinder of length \(N \gg 1\). Since the system is translationally invariant in vertical direction, we can equally well carry out our analysis in Fourier space, and we will do so in the following. By combining Eqs. (46), (47), and (48) we immediately find that \(\Phi_1\) is described by a CM of the form

\[
\hat{\Gamma}_1 \equiv \begin{pmatrix}
\hat{A}_1 & \hat{B}_{1,R} & \hat{B}_{1,T} \\
-\hat{B}_{1,R}^\dagger & \hat{R}_1 & S_1 \\
-\hat{B}_{1,T}^\dagger & -\hat{S}_1^\dagger & \hat{T}_1
\end{pmatrix},
\]

with \(\hat{R}_1, \hat{S}_1,\) and \(\hat{T}_1\) defined in Eq. (49). The concatenation of \(N\) columns is then given by the Schur complement

\[
\hat{\Gamma}_N = \hat{P}_N + \hat{Q}_N \hat{V}_N^{-1} \hat{Q}_N^\dagger,
\]

with

\[
\hat{P}_N = \begin{pmatrix}
\hat{R}_1 & -\hat{B}_{1,R}^\dagger & 0 & \cdots \\
\hat{B}_{1,R} & \hat{A}_1 & 0 & \cdots \\
0 & 0 & \hat{A}_1 & \cdots \\
\vdots & \vdots & \ddots & \ddots \\
0 & \hat{A}_1 & -\hat{B}_{1,T}^\dagger & \hat{T}_1
\end{pmatrix},
\]

\[
\hat{Q}_N = \begin{pmatrix}
\hat{S}_1 & \hat{B}_{1,R} & \hat{B}_{1,T} \\
\hat{B}_{1,T} & \cdots & \hat{B}_{1,R} & \hat{B}_{1,T} \\
\vdots & \ddots & \ddots & \ddots \\
\hat{B}_{1,R} & \hat{B}_{1,T} & \hat{B}_{1,R} & \hat{B}_{1,T}
\end{pmatrix},
\]

\[
\hat{V}_N = \begin{pmatrix}
\hat{T}_1 & 1 & 0 & \cdots & 0 \\
-1 & \hat{R}_1 & \hat{S}_1 & \cdots & 0 \\
0 & -\hat{S}_1^\dagger & \hat{T}_1 & 1 & \cdots \\
\vdots & \vdots & \vdots & \ddots & \ddots \\
0 & \hat{S}_1^\dagger & \hat{T}_1 & 1 & \cdots \\
-1 & \hat{R}_1 & \hat{S}_1 & \cdots & 1
\end{pmatrix},
\]

where we have moved the virtual edge modes on the left (right) boundary to the left (right) corner of the CM, as indicated by the lines above.

Let us now first show that the two virtual edges are decoupled. To this end, we consider the reduced state of the virtual system of \(\Phi_N\), which is given by the CM \(G\) in Eq. (11): evidently, vanishing off-diagonal blocks in \(G\) (and \(\hat{G}\)) imply that any coupling between the two boundaries in \(\Sigma_N\), Eq. (10), vanishes as well. \(G\) is given by the two outer blocks of \(\hat{G}_N\). Obviously, the only way in which these two blocks can couple is via \(\hat{V}_N^{-1}\).

We now invoke a result on the inverse of banded matrices.\(^{16}\) Given a banded matrix \(A_b\), it holds that 

\[
|\langle A_b^{-1}\rangle_{ij} | \leq \text{const.} \times \beta^{i-j}, \text{where } \beta < 1 \text{ depends on the ratio of the largest and smallest eigenvalue of } A_b A_b^\dagger \text{ (and } \beta \to 1 \text{ if the ratio diverges). Using this result, we find that the coupling between the two edges in } G \text{ is exponentially suppressed in the length } N \text{ of the cylinder, as desired, as long as the ratio of the eigenvalues of } \hat{V}_N \hat{V}_N^\dagger \text{ does not diverge. Its largest eigenvalue is clearly bounded by } 4, \text{ since } \hat{V}_N \hat{V}_N^\dagger \text{ is the sum of two CMs. To lower bound the smallest eigenvalue, observe that } \hat{V}_N \hat{V}_N^\dagger \text{ is again a banded Toeplitz matrix, which we can regard as a subblock of a larger circulant matrix. This circulant matrix can in turn be diagonalized using a Fourier transform, and we find that it is of the form } (\hat{D}_1 + \hat{\omega}^{-1}(k_x, k_y))(\hat{D}_1 + \hat{\omega}^{-1}(k_x, k_y))^\dagger. \text{ On the other hand, det } [\hat{D}_1 + \hat{\omega}^{-1}(k_x, k_y)] \text{ is exactly the energy spectrum of the local parent Hamiltonian as constructed in Ref. 22, and thus, } \hat{V}_N^{-1} \equiv \hat{V}_N^{-1}(k_y) \text{ has exponentially decaying entries if and only if the parent Hamiltonian is gapped for the given value of } k_y \text{ (which is the case for almost all } k_y).\]

As we have seen, (almost) all virtual edge modes on the left and right of the cylinder decouple. In the following, we will show that also the physical modes corresponding to these edge modes are exponentially localized around the corresponding boundary. To this end, we fix \(N \gg 1\) and consider the CM \(\Gamma'\), Eq. (42), which is obtained by an orthogonal transformation from the original CM \(\Gamma \equiv \Gamma_N\). In \(\Gamma'\), the edge modes are supported on the \((2,2)\) block, and we need to figure out how the inverse of the orthogonal transformation \(M\), Eq. (44), maps these back to the physical modes.

To this end, note that in order to prepare an arbitrary state in the \((2,2)\) block of \(\Gamma'\), Eq. (45), we just need to project the \((3,3)\) block on an (unphysical) CM \(X\) via the Schur complement formula Eq. (48). In particular, we can use this to occupy or deplete a specific mode. (We assume \(\chi\) to be even; otherwise, one can simply group pairs of modes.) Consequently, by projecting the original CM \(\Gamma_N\) onto the very same \(X\), we will exactly occupy or deplete the corresponding physical mode. Now, we can make use of Eq. (48), together with the aforementioned result on inverses of banded matrices: Given \(X\) and \(X'\) such that projecting onto \(X\) (\(X'\)) occupies (depletes) a certain mode at one boundary, and denoting by \(\gamma(X)\) \([\gamma(X')]\) the corresponding CMs after the projection, we
have that
\[ \gamma(X) - \gamma(X') = \hat{Y} \left[ \hat{Z} + X^{-1} - (\hat{Z} + X'^{-1}) \right] \hat{Y}^\dagger, \]
where \( \hat{Y} \) and \( \hat{Z} \) denote the corresponding submatrices of \( \Gamma_N \). Importantly, \( \hat{Y} \) decays exponentially in distance as it is a column of \( \Gamma_N \). Since we have that
\[ [\gamma(X) - \gamma(X')]_{l,m} = 2i(v_l v_m^* - w_l w_m^*) \]
with \( \sum_l v_l c_l \) and \( \sum_l w_l c_l \) the creation/annihilation operator for the corresponding physical mode, it follows that \( v_l \) and \( w_l \) decay exponentially with the distance from the corresponding boundary, i.e., the physical edge mode corresponding to a given virtual edge mode is localized around that edge.

IV. FURTHER EXAMPLES

In this Section, we will present further examples for both chiral and non-chiral GFPEPS, and discuss their respective boundary theories. In Subsection A, we discuss a Chern insulator with \( C = -1 \); in Subsection B, we discuss a model with \( C = 2 \) which has entangled edge modes at incommensurate values of \( k_y \); and in Subsections C and D, we discuss two non-chiral models.

A. GFPEPS describing a Chern insulator with \( C = -1 \)

In the following, we study the family of chiral GFPEPS presented in Ref. 22, which are particle number conserving and describe a Chern insulator with \( C = -1 \). They can be decoupled into two copies of a topological superconductor which closely related to the family of Eq. 17. This family has \( f = 2 \) physical fermionic modes per site, \( \chi = 2 \) Majorana bonds, and \( \gamma_1 \) [Eq. 15] is defined via
\[
A = (-1 + 2\eta) \begin{pmatrix} W & 0 \\ 0 & -W \end{pmatrix},
\]
\[
B = \left( \eta - \eta^2 \right) \begin{pmatrix} 1 & -1 + \eta \\ 1 & 1 \\ 1 & -1 + \eta \\ 1 & 1 \\ 1 & -1 + \eta \\ 1 & 1 \\ 1 & -1 + \eta \\ 1 & 1 \\ 1 & -1 + \eta \\ 1 & 1 \\ 1 & -1 + \eta \\ 1 & 1 \\ 1 & -1 + \eta \\ 1 & 1 \end{pmatrix},
\]
\[
D = \begin{pmatrix} 0 & (-1 + \eta) & 0 & (-1 + \eta) \\ (-1 - \eta) & \eta & (-1 + \eta) & \eta \\ \eta & (-1 - \eta) & \eta & (-1 + \eta) \\ (-1 + \eta) & \eta & (-1 - \eta) & \eta \end{pmatrix},
\]
where \( \mathbb{1} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \), \( W = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \) and \( \eta \in (0, 1) \). The ordering of the physical Majorana modes is \( \{c_1, c_2\} \), and the blocks of \( D \) are ordered according to left, right, up, and down virtual modes.

The boundary \( \hat{\Sigma}_\infty(k_y) \) can be computed using the results of Sec. V and we find it to be of the form
\[
\Sigma_\infty = \left( \bigoplus_{k_y \neq \pi} \left( \hat{\Sigma}_\infty^{\mathbb{R}}(k_y) \oplus \hat{\Sigma}_\infty^{\mathbb{R}}(k_y) \right) \oplus \hat{\Sigma}_\infty^{\mathbb{R}}(\pi) \right) \otimes \mathbb{1}
\]
with \( \hat{\Sigma}_\infty^{\mathbb{R}}(\pi) = \left( \begin{pmatrix} 0 & \pm 1 \\ \mp 1 & 0 \end{pmatrix} \right) \), the sign depending on whether the horizontal length \( N \) of the cylinder is even or odd. In Fig. 12 we show the spectrum of the boundary Hamiltonian of the above model (top panel). Moreover, we illustrate how for \( N \to \infty \) the edge Hamiltonian for a single edge converges (middle panel) and how the coupling between the two edges vanishes (bottom panel).

The Chern number can now be determined by counting the number of times the bands of \( -i\Sigma_\infty^{\mathbb{R}}(k_y) \otimes \mathbb{1} \) (or, alternatively, of \( -i\hat{H}_\infty^{\mathbb{R}}(k_y) \otimes \mathbb{1} \)) cross the Fermi level. Obviously, the spectrum of the boundary and edge Hamiltonian consists of two bands lying on top of each other. In the language of topological superconductors, this would give rise to a Chern number of \(-2\). However, since we assume particle number conservation (as we deal with a Chern insulator), the Chern number is given by the number of fermionic chiral modes of the edge or boundary Hamiltonian, respectively. There is only one such fermionic chiral mode (annihilation operator \( a_{k_y} \)), which is obtained by combining the two chiral Majorana modes on the right edge, \( \hat{c}_{1,k_y} \) and \( \hat{c}_{2,k_y} \), with equal dispersion to \( a_{k_y} = \frac{1}{2}(\hat{c}_{1,k_y} - i\hat{c}_{2,k_y}) \). In this case, combining the Majorana modes does not make the system topologically trivial, since both of them have the same chirality. Therefore, the (particle number conserving) Chern number is \( C = -1 \).

B. GFPEPS with Chern number \( C = 2 \)

In the following, we provide an example of a topological superconductor with \( \chi = 2 \) and Chern number \( C = 2 \). The model has been constructed numerically such that it exhibits discontinuities in \( \hat{\Sigma}_\infty(k_y) \) and thus pure fermionic modes between the edges maximally entangled modes between the edges at \( k_y = \pm 1 \); it thus demonstrates that for \( \chi > 1 \), there is no constraint (in terms of simple fractions of \( \pi \)) on the possible values of \( k_y \). The CM \( D \) of the example is given by
\[
D \approx \begin{pmatrix} 0 & -0.326 & -0.250 & 0.510 & 0.297 & 0.071 & -0.434 & -0.030 \\ 0.326 & 0 & 0.044 & -0.074 & -0.513 & 0.032 & -0.051 & 0.577 \\ 0.250 & -0.044 & 0 & -0.467 & 0.036 & 0.635 & -0.423 & -0.125 \\ -0.510 & 0.074 & 0.467 & 0 & 0.148 & 0.156 & 0.169 & 0.216 \\ -0.295 & 0.513 & -0.036 & -0.148 & 0 & -0.161 & -0.296 & 0.237 \\ -0.071 & -0.032 & -0.603 & -0.156 & 0.161 & 0 & 0.042 & 0.521 \\ 0.434 & 0.051 & 0.423 & -0.169 & 0.296 & -0.042 & 0 & 0.047 \\ 0.030 & -0.577 & 0.125 & -0.216 & -0.237 & -0.521 & -0.047 & 0 \end{pmatrix}.
\]
It has been obtained by numerically optimizing \( D \) such that one of the eigenvalues of \( \Sigma_\infty^{\mathbb{R}}(k_y) \) (where \( N = 2^{29} \)) jumps from \( \pm i \) to \( \mp i \) for some \( k_y \in [0.999, 1.001] \), while restricting half of the eigenvalues of \( D \) to be between \( \pm 0.61 \) such as to prevent \( D \) from converging to a pure state. As \( \Sigma_\infty^{\mathbb{R}}(k_y) = [\Sigma_\infty(k_y)]^\dagger \) (with * indicating the
complex conjugate), this automatically yields another identical discontinuity at \( k_y = -1 \). Note that \( D \) can be purified to a state with \( f = 2 \) physical fermions.

The spectrum of \(-i\hat{H}_R^\infty(k_y)\) is plotted in Fig. 13. Due to the discontinuities at \( k_y \pm 1 \), it crosses the Fermi energy twice from below, thus describing a topological superconductor with Chern number \( C = 2 \). At \( k_y = \pm 1 \), one of the eigenvalues of \(-i\hat{H}_R^\infty(k_y)\) diverges, and thus \( \Sigma_{LR}^\infty(k_y) \) is non-trivial, coupling one of the two virtual Majorana modes between the left and the right end of the cylinder.

C. GFPEPS with Chern number \( C = 0 \)

The following example provides a family of non-topological GFPEPS with Chern number \( C = 0 \). It has one parameter \( \mu \), and its matrix \( D \) is given by

\[
D = \begin{pmatrix}
0 & 0 & \frac{-i}{2} & f(\mu) \\
0 & 0 & f(\mu) & -\mu \\
\frac{\mu}{2} & -f(\mu) & 0 & 0 \\
-f(\mu) & \mu & 0 & 0 \\
\end{pmatrix}
\]  

(56)

with \( f(\mu) = \sqrt{1 - \frac{\mu^2}{4} + \frac{\mu^4}{4}} \) and \( \mu \in (0, 1) \). \( A \) and \( B \) can be obtained by choosing an arbitrary purification.

We find that the left and right boundary, Eq. 50, decouple for all \( k_y \). The dispersion relation for the right boundary is shown in Fig. 8. Since the energy band of the boundary Hamiltonian crosses the Fermi energy once with positive and once with negative slope for all \( \mu \in (0, 1) \), the Chern number is always zero.

FIG. 12. Analysis of the boundary and edge Hamiltonian of the model of Sec. IV A using the form of Eq. 55. Top: Boundary Hamiltonian \(-i\hat{H}_R^\infty(k_y)\) for different values of \( \eta \). Middle: Convergence of the right edge spectrum \( \hat{\Sigma}_N \) for \( \eta = 1/2 \) and increasing cylinder length \( N = 1, 3, 8, 100 \). For \( N = 100 \), the spectrum is already well converged. Bottom: Magnitude of the corresponding off-diagonal element of \( \hat{D}_N \) which describes the coupling of the two boundaries (cf. Sec. III B 2), for cylinder lengths \( N = 1, 3, 8, 100 \), illustrating the exponential decoupling in \( N \).

FIG. 13. Eigenvalue spectrum of \(-i\hat{H}_R^\infty(k_y)\) for the example of Sec. IV B. Since \( \chi = 2 \), there are two bands. They diverge at \( k_y = \pm 1 \), respectively, where only one mode of \( \hat{H}_R^\infty(k_y) \) is defined. Since the Fermi level at \( E = 0 \) is crossed two times from below, \( C = 2 \). The dispersionless bulk bands of the (truncated) flat band Hamiltonian \( H_R \) correspond to an energy of \( \pm \infty \).
D. GFPEPS with flat entanglement spectrum and \( C = 0 \)

The last example we consider is taken from Ref.\textsuperscript{25} it does not display any topological features. It is given by

\[
\gamma_1 = \begin{pmatrix}
0 & 0 & \frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} & 0 & 0 \\
0 & 0 & 0 & 0 & \frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} \\
-\frac{1}{\sqrt{2}} & 0 & 0 & 0 & \frac{1}{2} & \frac{1}{2} \\
\frac{1}{\sqrt{2}} & 0 & 0 & 0 & \frac{1}{2} & \frac{1}{2} \\
0 & -\frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} & 0 & 0 & 0 \\
0 & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & 0 & 0 & 0
\end{pmatrix}.
\]

(57)

Since \( \tilde{D}_N = \tilde{\hat{D}}_N \), and thus \( \hat{G} = \tilde{G} \), the entanglement spectrum and edge Hamiltonian of this model are totally flat, i.e., \( \Sigma_N = 0 \) according to Eq. \textsuperscript{16}, and the Chern number is zero.

V. FULL SOLUTION FOR \( \chi = 1 \)

In this Section, we will use the recursion relation \textsuperscript{50} to explicitly derive the boundary and edge theories for GFPEPS with one Majorana mode per bond, \( \chi = 1 \). We will then use this result to show that the presence of chiral edge modes is related to the occurrence of Majorana modes maximally correlated between the two edges, i.e., a fermionic mode in a pure state shared between the two edges.

We start by deriving a closed expression for the boundary and edge Hamiltonian for \( \chi = 1 \). In this case, \( \hat{D} \)

\[
\hat{D} = \begin{pmatrix}
i\hat{r} & i\hat{s} \\
i\hat{s}^* & i\hat{t}
\end{pmatrix},
\]

(58)

with scalar functions \( \hat{r} \equiv \hat{r}(k_y) \in \mathbb{R}, \hat{t} \equiv \hat{t}(k_y) \in \mathbb{R} \), and \( \hat{s} \equiv \hat{s}(k_y) \). Note that for given \( k_y \), the eigenvalues need not to come in complex conjugate pairs. However, they are still bounded by one, which implies that for \( \hat{r} \hat{t} \geq 0 \),

\[
1 - \sqrt{\hat{r} \hat{t}} \geq |\hat{s}| \text{ with equality iff } |\hat{s}| = 1,
\]

(59)

which in turn implies that for all \( \hat{r} \) and \( \hat{t} \),

\[
1 - \hat{r} \hat{t} \geq |\hat{s}| \text{ with equality iff } |\hat{s}| = 1.
\]

(60)

(For \( \hat{r} \geq 0 \) and \( \hat{t} \geq 0 \), Eq. \textsuperscript{59} follows from \( 2 \geq -i(1, \frac{\hat{s}}{\hat{t}}) \hat{D}_1(1, \frac{\hat{s}}{\hat{t}})^\dagger = \hat{r} + \hat{t} + 2|\hat{s}| \geq 2\sqrt{\hat{r} \hat{t}} + 2|\hat{s}| \), and similarly for \( \hat{r} \leq 0 \) or \( \hat{t} \leq 0 \).)

Let us now study what happens when we concatenate cylinders; for the CM of \( N \) columns, we will write \( \hat{D}_N \) and \( \hat{r}_N, \hat{s}_N, \) and \( \hat{t}_N \). The iteration relation \textsuperscript{59} yields the following iteration relations for the matrix elements:

\[
\hat{r}'' = \hat{r} + \hat{r}' \frac{\hat{s}_N^2}{1 - \hat{r} \hat{t}}
\]

(61a)

\[
\hat{t}'' = \hat{t} + \hat{t}' \frac{\hat{s}_N^2}{1 - \hat{r} \hat{t}}
\]

(61b)

\[
\hat{s}'' = \frac{\hat{s}_N \hat{s}'}{1 - \hat{r} \hat{t}}.
\]

(61c)

For \( \hat{z} = \hat{z}' = \hat{z}_N \) (\( \hat{z} = \hat{r}, \hat{s}, \hat{t} \), and \( \hat{z}'' = \hat{z}_{2N} \), with \( N \) a power of 2 (i.e., doubling the number of columns in each step), we obtain

\[
\hat{r}_{2N} = \hat{r}_N (1 + \hat{\xi}_N)
\]

(62a)

\[
\hat{t}_{2N} = \hat{t}_N (1 + \hat{\xi}_N)
\]

(62b)

\[
\hat{s}_{2N} = \frac{\hat{s}_N \hat{z}_N}{\hat{z}_N}
\]

(62c)

with

\[
\hat{\xi}_N = \frac{\hat{s}_N^2}{1 - \hat{r}_N \hat{t}_N}.
\]

(63)

Assume for now \( |\hat{s}_N| < 1 \): Then, \( \hat{\xi}_N \Rightarrow \hat{\xi}_N < 1 \Rightarrow |\hat{s}_{2N}| < 1 \), and thus \( |\hat{s}_1| < 1 \) implies \( |\hat{s}_N| < 1 \). Moreover, Eq. \textsuperscript{62} implies \( |\hat{s}_{2N}| < |\hat{s}_N| \), which in turn implies that \( |\hat{s}_N| \) converges; similarly, since \( \hat{\xi}_N \geq 0 \), \( \hat{r}_N \) and \( \hat{t}_N \) monotonously move away from zero and thus converge. We therefore find that for \( |\hat{s}_N| < 1 \), all matrix elements converge.

On the other hand, \( |\hat{s}_1| = 1 \) implies that \( \hat{r}_1 = \hat{t}_1 = 0 \) (as \( \hat{D}_1 \) must have spectral radius \( \leq 1 \)), and thus \( \hat{z}_{\infty} = \hat{z}_\infty = 0 \), while \( |\hat{s}_\infty| = 1 \). An explicit analysis of the possible \( \hat{D}_1 \) for \( \chi = 1 \), using Eq. \textsuperscript{18}, shows that \( \hat{r}_1(k_y) = \hat{t}_1(k_y) = 0 \) can only be the case for \( k_y = 0 \) or \( k_y = \pi \), unless both vanish identically (in which case the fixed point and the GFPEPS are trivial).

In order to determine the fixed point for \( |\hat{s}_1| < 1 \) (\( N \rightarrow \infty \)), we now consider the scenario where \( \hat{z} = \hat{z}'' = \hat{z}_\infty \) and \( \hat{z}' = \hat{z}_1 \), i.e., where we append a single column to an infinite cylinder. From \textsuperscript{61a}, we find that

\[
\hat{\xi}_\infty = \hat{\xi}_1 + \hat{\xi}_1 \frac{|\hat{s}_\infty|}{1 - \hat{r}_1 \hat{t}_\infty} \frac{|\hat{s}_\infty|}{1 - \hat{r}_1 \hat{t}_\infty}
\]

and thus \( \hat{\xi}_\infty = 0 \) for \( \hat{\xi}_1 \neq 0 \) and similarly if \( \hat{\xi}_1 \neq 0 \); if \( \hat{r}_1 = \hat{t}_1 \), Eq. \textsuperscript{61c} yields \( \hat{z}_\infty = \hat{s}_\infty \hat{s}_1 \), which as well implies \( \hat{s}_\infty = 0 \) as long as \( |\hat{s}_1| < 1 \). On the other hand, Eq. \textsuperscript{61b} yields a quadratic equation for \( \hat{t}_\infty \),

\[
\hat{r}_1 \hat{t}^2 + (1 + \hat{r}_1 \hat{t}_1 - |\hat{s}_1|^2) \hat{t}_\infty + \hat{t}_1 = 0,
\]

(64)

and similarly for \( \hat{r}_\infty \) by exchanging \( \hat{r} \) and \( \hat{t} \). Of the two solutions

\[
\hat{r}_\infty = \frac{\hat{\Delta}_1 \pm \sqrt{\hat{\Delta}_1^2 - 4\hat{\Delta}_1 \hat{\Delta}_2}}{2\hat{\Delta}_1}
\]
[where \( \hat{\Delta}_1 = 1 + \hat{r}_1 \hat{t}_1 - |\hat{s}_1|^2 = \text{det}(i\hat{D}_1) + 1 \geq 0 \), the fixed point is always given by \( \hat{r}_\infty, \hat{t}_\infty \). This is seen by noting that \( -1 \leq \hat{t}_{\infty} \leq 1 \) implies that \( \pm 2\hat{r}_1 - \hat{\Delta}_1 \geq \sqrt{\hat{\Delta}_1^2 - 4\hat{r}_1 \hat{t}_1} \) (with \( \pm \) the sign of \( \hat{r}_1 \)), squaring which yields \( 0 \geq (\hat{r}_1 + 1)(\hat{t}_1 + 1) - |\hat{s}_1|^2 = \text{det}(i\hat{D}_1 + \hat{I}) \), and thus \( \hat{t}_{\infty} \) can only be physical if \( \hat{t}_1 \) has an eigenvalue \( \pm 1 \); and these remaining cases can be easily analyzed by hand. We thus find that the fixed point CM is of the form

\[
\hat{D}_\infty = \begin{pmatrix}
  i\hat{r}_{\infty}^+ & 0 \\
  0 & i\hat{r}_{\infty}^-
\end{pmatrix},
\]

except when \( |\hat{s}_1| = 1 \), which we found can only happen at \( k_y = 0, \pi \) (in which case \( \hat{s}_1(k_y) \) is real).

In order to obtain the boundary theory, we need to combine the expression for \( \Sigma_N \), Eq. (50), with the fact that \( \hat{G} \) and \( \hat{G} \) are given by \( \hat{G} = i\hat{r}_\infty \hat{t}_\infty \) and \( \hat{G} = i\hat{r}_\infty \hat{t}_\infty \), with the exception of the singular points in \( k_y \)-space where \( |\hat{s}_\infty| = 1 \). In particular, the two boundaries can be described independently almost everywhere, and we obtain for the edge theory of the right edge \( (\hat{t}_\infty = \hat{t}_1, \hat{r}_\infty = \hat{r}_\infty) \)

\[
\Sigma R_\infty(k_y) = -i\hat{t}_\infty - i(1 - \hat{t}_{\infty}^2)(\hat{t}_\infty - \hat{r}_\infty)^{-1} = i \frac{\hat{r}_1 - \hat{t}_1}{\sqrt{\hat{\Delta}_1^2 - 4\hat{r}_1 \hat{t}_1}},
\]

with the boundary Hamiltonian given by \( \hat{H}^R_{\infty}(k_y) = 2\arctan(\Sigma R_\infty(k_y)) \); for the opposite edge, \( \hat{r} \) and \( \hat{t} \) need to be interchanged. For the points with \( |\hat{s}_1| = |\hat{s}_\infty| = 1 \), on the other hand, the two boundaries are in a maximally entangled state of the Majorana modes with the corresponding \( k_y \).

Clearly, \( \Sigma R_\infty(k_y) \) [Eq. (55)] is continuous unless the denominator becomes zero. For the latter to happen, one first needs that \( \hat{r}_1 \hat{t}_1 \geq 0 \), and with this, \( \hat{\Delta}_1^2 - 4\hat{r}_1 \hat{t}_1 = 0 \) is equivalent to \( 1 - \sqrt{\hat{r}_1 \hat{t}_1} = |\hat{s}_1| \), which using Eq. (49) implies that \( |\hat{s}_1| = 1 \), which can only be the case for \( k_y = k_y^0 = 0, \pi \). In order to analyze how \( \Sigma R_\infty(k_y) \) behaves around such a point, we expand to first order in \( \delta k_y = k_y - k_y^0 \): Then, \( \hat{r}_1 = \hat{r}_1^0 \delta k_y + O(\delta k_y^2) \), \( \hat{t}_1 = \hat{t}_1^0 \delta k_y + O(\delta k_y^2) \), and \( |\hat{s}_1| = 1 + O(\delta k_y^2) \) (since \( |\hat{s}_1| \leq 1 \)). One immediately finds that

\[
\Sigma R_\infty(k_y) = i \frac{(\hat{r}_1^0 - \hat{t}_1^0) \delta k_y + O(\delta k_y^2)}{\sqrt{-4\hat{r}_1^0 \hat{t}_1^0 \delta k_y^2 + O(\delta k_y^2)}} = i \text{sign}(\delta k_y) \frac{\hat{r}_1^0 - \hat{t}_1^0}{\sqrt{-4\hat{r}_1^0 \hat{t}_1^0}} + O(\delta k_y),
\]

this is, \( \Sigma R_\infty(k_y) \) exhibits a discontinuity unless \( \hat{r}_1^0 = \hat{t}_1^0 \). In order to relate \( \hat{r}_1^0 \) and \( \hat{t}_1^0 \), we observe that the eigenvalues of \( \hat{D}_1 \) around \( k_y^0 \) are \( i(\pm 1 + \frac{1}{2}(\hat{r}_1^0 + \hat{t}_1^0)) \delta k_y + O(\delta k_y^2) \), and thus \( \hat{r}_1^0 + \hat{t}_1^0 = 0 \), which implies that

\[
\Sigma R_\infty(k_y) = i \text{sign}(\delta k_y) \text{sign}(\hat{r}_1^0(k_y^0)).
\]

VI. SYMMETRY AND CHIRALITY

As we have seen in the preceding section, the existence of a chiral edge mode is equivalent to the existence of a maximally entangled Majorana mode between the left and right edge of the cylinder at \( k_y^0 = 0 \) or \( k_y^0 = \pi \). In the following, we will show that this mode can be understood as arising from a local symmetry of the state \( \Psi_1 \) which defines the GFPEPS (Eq. (1)).

Concretely, in part A we will demonstrate that a certain symmetry of \( \Psi_1 \) leads to a maximally entangled Majorana pair between the left and right edge and thus a chiral edge state. In part B we will show the opposite – that a maximally entangled Majorana pair between the left and the right implies \( \Psi_1 \) having a certain symmetry. In part C we uncover these kinds of symmetries in the examples presented in the previous sections. In part D we consider again the example given by Eq. (12) and outline how strings of symmetry operators can be used to construct all ground states of its frustration free parent Hamiltonian \( \mathcal{H}_\Pi \).

We will generally restrict the discussion in this Section to the case of \( \chi = 1 \) Majorana mode per bond, though some of the results (in particular in Subsection A) directly generalize to larger \( \chi \).

A. Sufficiency of local symmetry

We start by showing how a symmetry in \( \Psi_1 \) induces a symmetry on a whole column, \( \Phi_1 \), and how this subsequently gives rise to a maximally correlated mode between the two edges of a cylinder. Since \( \Psi_1 \) is a pure
Gaussian state where four virtual Majorana modes are entangled with one physical fermionic mode, there must be a virtual fermionic mode which is in the vacuum, i.e.,

\[ d_1 = \alpha_L c_L + \alpha_R c_R + \alpha_U c_U + \alpha_D c_D \]  

(66)
on the virtual system which annihilates \( \Psi_1 \),

\[ d_1 |\Psi_1\rangle = 0 \]  

(67)
as already discussed in Sec. [11][d_1 \text{ corresponds to the eigenvector of } D, \text{ Eq. (3), with eigenvalue } -i, \text{ and describes a fermionic mode}]. We will refer to \( d_1 \) as a symmetry, since it corresponds to a \( \mathbb{Z}_2 \) symmetry of \( \Psi_1 \) with \( U_1 = 1 - 2d_1^\dagger d_1 \). On the other hand, for the virtual fermionic modes \( \omega_{12} \) (the indices denoting the vertical positions), Eq. (37), it holds that

\[ \langle \omega_{12} | (1 - ic_{1,D}c_{2,U}) = 0 \]  

(68)
By combining Eqs. (67) and Eq. (28), we can now study how the symmetry \( d_1 \) behaves when we concatenate two or more sites by projecting onto \( \langle \omega_{12} \rangle \) (we assume \( \alpha_U \neq 0 \) for now, and define \( \theta := i\alpha_D/\alpha_U \)):

\[ 0 = \langle \omega_{12} | \left( [\alpha_L c_{1,L} + \alpha_R c_{1,R} + \alpha_U c_{1,U} + \alpha_D c_{1,D}] |\Psi_1, \Psi_1\rangle_{1,2} + \theta [\alpha_L c_{2,L} + \alpha_R c_{2,R} + \alpha_U c_{2,U} + \alpha_D c_{2,D}] |\Psi_1, \Psi_1\rangle_{1,2} \right) 
\]

\[ = d_2 \langle \omega_{12} | |\Psi_1, \Psi_1\rangle_{1,2} = d_2 |\Psi_2\rangle \]
with

\[ d_2 = \alpha_L (c_{1,L} + i\theta c_{2,L}) + \alpha_R (c_{1,R} + i\theta c_{2,R}) + \alpha_U c_{1,U} + \theta \alpha_D c_{2,D} \]
the symmetry of the concatenated state \( \Psi_2 \), Fig. 1b and Fig. 14a. The argument can be easily iterated, and we find that

\[ d_N |\Psi_N\rangle = 0 \]
with

\[ d_N = \alpha_L \sum_{y=1}^{N_x} \theta^{y-1} c_{y,L} + \alpha_R \sum_{y=1}^{N_x} \theta^{y-1} c_{y,R} + \alpha_U c_{1,U} + \theta \alpha_D c_{N_x,D} \]

(69)
Let us now see what happens when we close the boundary between sites \( N_x \) and 1, which yields \( |\Phi_1\rangle = \left( \omega_{N_x,1} |\Psi_{N_x}\rangle \right) \), Fig. 1c: Since \( \langle \omega_{N_x,1} | (c_{N_x,D} + ic_{1,U}) = 0 \), we find that

\[ d_0 |\Phi_1\rangle = 0 \]
(70)
(Fig. 1d-f) whenever \( \theta^{N_x} = 1 \). This leads to two requirements for the existence of \( d_0 \) fulfilling Eq. (69):

First, \( |\alpha_U| = |\alpha_D| \), and second, the momentum \( k_y^0 \)
of \( d_0 \) (defined via \( e^{ik_y^0 s} = \theta \)) must be commensurate with the lattice size. Whenever these requirements are fulfilled, we thus find that the local symmetry \( d_1 \), Eq. (66), gives rise to a symmetry \( d_0 \propto \alpha_L c_{L,k_y} + \alpha_R c_{R,k_y} \)
(71), on the whole column (i.e., on \( D_1 \)), at momentum \( e^{ik_y^0} = i\alpha_D/\alpha_U \). Note that we only need to assume that either \( \alpha_U \) or \( \alpha_D \) is non-zero; if both are zero, the condition \( d_0 \) implies that the horizontal virtual modes entirely decouple from the physical system, and the GFPEPS describes a product of one-dimensional vertical chains.

We have thus found that a certain local symmetry induces a symmetry on a column \( \Phi_1 \), which forces the Majorana modes with a specific momentum on both ends of the column to be correlated. This is equivalent to demanding that for this \( k_y^0 \) \( D_1(k_y^0) \) has an eigenvalue \( -i \). For \( k_y^0 = 0, \pi \), this implies that \( |\tilde{s}_1(k_y^0)| = 1 \), as the diagonal elements of \( D_1(k_y^0) \) are zero due to \( D_1(-k_y^0) = D_1^*(k_y^0) \).

The symmetry of a single column is passed on when concatenating columns, this is, when going from \( \Phi_1 \) to \( \Phi_N \), Fig. 1d-f, in analogy to the arguments given before. In order for this to lead to a coupling between the two edge modes in the limit of an infinite cylinder, as observed in the examples with chiral edge modes, it is additionally required that \( |\alpha_L| = |\alpha_R| \). Otherwise the symmetry becomes localized at a single boundary. This can be understood by exchanging horizontal and vertical directions, leading to \( e^{ik_x^0} = i\alpha_L/\alpha_R \) (and \( k_y^0 = 0, \pi \), too).

As we have seen in the last Section, a coupling between the left and the right edge for \( \chi = 1 \) can only emerge, if \( k_y^0 = 0, \pi \) (and analogously \( k_x^0 = 0, \pi \)). Thus, we have to require \( \alpha_D/\alpha_U = \pm i, \alpha_R/\alpha_L = \pm i \) for a symmetry

\[ a) \quad d_1 = 0 \]
\[ b) \quad d_2 = 0 \]
\[ c) \quad d_0 = 0 \]

FIG. 14. Concatenation of a symmetry. (a) Symmetry \( d_1 \) annihilating the state \( \Psi_1 \) of virtual and physical Majorana fermions on one site. For a chiral state with \( \chi = 1 \) it can be concatenated as described in the text to a symmetry \( d_2 \) annihilating the state \( \Psi_2 \) defined on two sites (b). Proceeding in the same manner and closing the vertical boundary, one obtains a symmetry \( d_0 \) annihilating one column \( \Phi_1 \) (c).
leading to a chiral edge state. Since there can only be one such symmetry for \( \chi = 1 \) (otherwise the virtual and physical system decouple), we conclude that there can be a maximally entangled Majorana mode only for \( k^0_y = 0 \) or \( k^0_y = \pi \), but not for both of them (and similarly for \( k_z \)). We thus find that \( d_1 \) must be of the form
\[
d_1 = \alpha_L (c_L + ic_R) + \alpha_U (c_U + ic_D) \, .
\] (\( \alpha_L, \alpha_U \neq 0 \)) in order to be stable under concatenation.

Let us finally show that in order to have a non-trivial Chern number, there is an additional constraint on \( \alpha_L \) and \( \alpha_U \), namely that
\[
\arg \left( \frac{\alpha_L}{\alpha_U} \right) \notin \{ 0, \pi, \pm \frac{\pi}{2} \} \, .
\] (72)

This can be directly verified by explicitly constructing \( D \) (given \( d_1 \)), the only remaining freedom is the eigenvalue of the non-pure mode), where one finds that the diagonal (off-diagonal) elements of \( K \) [cf. Eq. (71)] vanish exactly if \( \arg \left( \frac{\alpha_L}{\alpha_U} \right) = 0, \pi \) [\( \arg \left( \frac{\alpha_L}{\alpha_U} \right) = \pm \frac{\pi}{2} \)]. As we have seen in the last section, this in turn is equivalent to a trivial (completely flat) edge spectrum, and thus to a trivial Chern number.

In summary, we find that we have a non-trivial Chern number whenever we have exactly one symmetry \( d_1 \) which satisfies Eqs. (71) and (72).

**B. Necessity of an on-site symmetry**

Let us now show the converse statement of the previous subsection: We will show that for \( \chi = 1 \), a maximally entangled Majorana pair between the left and right boundary of a cylinder at \( k^0_y = 0, \pi \), which is equivalent to the presence of a chiral edge mode, implies the existence of a local symmetry of the form Eq. (71).

Following the results in Sec. 4 we can find the presence of a maximally entangled Majorana pair on the boundary of a cylinder of arbitrary length is equivalent to the presence of the symmetry on a single column (i.e., a cylinder of length \( N = 1 \)), that is,
\[
\hat{D}_1(k^0_y) = \left( \begin{array}{cc} 0 & \mp 1 \\ \pm 1 & 0 \end{array} \right) \, .
\] (73)

According to Eq. (48), we also have
\[
\hat{D}_1(k^0_y) = H + K \left( V - \left( \begin{array}{cc} 0 & \pm 1 \\ \pm 1 & 0 \end{array} \right) \right)^{-1} K^\top \, .
\] (74)

where the upper sign is for \( k^0_y = 0 \) and the lower for \( k^0_y = \pi \) (and is unrelated to the sign in Eq. (71)). We choose in both cases the upper sign; the other cases can be treated analogously. Then, Eq. (74) tells us that \( \langle \omega_L | \Psi_1 \rangle \) (with \( \langle \omega_L | \) corresponding to the projection on \( \frac{1}{2} | 1 + ic_D \rangle \)) is in a maximally entangled state of the two horizontal Majorana modes. This maximally entangled state fulfills
\[
\langle \omega_L | \omega_R | \Psi_1 \rangle = 0 \, .
\] (75)

with \( \langle \omega_R | \) corresponding to the projection on \( \frac{1}{2} | 1 + ic_R \rangle \).

We now parameterize the reduced density matrix of the virtual system \( \rho_{\text{vir}} \) in the basis \( \{ \Omega_{\text{vir}}, | \omega_\nu \rangle, | \omega_\tau \rangle, | \omega_\nu \rangle, | \omega_\tau \rangle \} \) (\( \Omega_{\text{vir}} \) denoting the projection on the vacuum of the virtual particles and their subsequent discard). According to Eq. (75) its matrix representation is
\[
\rho_{\text{vir}} = \frac{1}{4} \begin{pmatrix} \rho_{00} & 0 & 0 & 0 \\ 0 & \rho_{hh} & \rho_{hv} & 0 \\ 0 & \rho_{vh} & \rho_{vv} & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \, .
\] (76)

From it, we can calculate the elements of \( D \) via \( D_{pq} = \frac{1}{2} \text{tr} (\rho_{\text{vir}} c_p \rho_v c_q) \) with \( p, q = L, R, U, D \), cf. Eq. (4), and obtain
\[
D = \begin{pmatrix} 0 & -\rho_{00} - \rho_{hh} + \rho_{vv} & 2\rho_{hh} - 2\rho_{hv} & 2\rho_{hv} - 2\rho_{hh} \\ -\rho_{00} - \rho_{hh} + \rho_{vv} & 0 & 2\rho_{hh} - 2\rho_{hv} & 2\rho_{hv} - 2\rho_{hh} \\ 2\rho_{hh} - 2\rho_{hv} & 2\rho_{hv} - 2\rho_{hh} & 0 & -\rho_{00} - \rho_{hh} + \rho_{vv} \\ 2\rho_{hh} - 2\rho_{hv} & 2\rho_{hv} - 2\rho_{hh} & -\rho_{00} - \rho_{hh} + \rho_{vv} & 0 \end{pmatrix} \cdot
\] (77)

The fact that \( \rho_{\text{vir}} \) describes a Gaussian state is used by inserting this into Eq. (74), which gives
\[
\rho_{00} = 1 - \sqrt{(\rho_{hh} - \rho_{vv})^2 + 4|\rho_{hv}|^2} \, .
\] (78)

Given this restriction, one can check that \( D \) in Eq. (77) has an eigenvalue \( -i \) with the corresponding symmetry \( d_1 = \alpha_L (c_L - ic_R) + \alpha_U (c_U - ic_D) \) fulfilling Eq. (71), where \( \alpha_L = 2\rho_{hv}^*, \alpha_U = -\rho_{hh} + \rho_{vv} - \sqrt{(\rho_{hh} - \rho_{vv})^2 + 4|\rho_{hv}|^2} \). After considering all possible sign cases in Eqs. (72), (74), one arrives at Eq. (71). We thus find that for a GFPEPS with \( \chi = 1 \), a (unique) symmetry of this form with \( \arg \left( \frac{\alpha_L}{\alpha_U} \right) \notin \{ 0, \pi, \pm \frac{\pi}{2} \} \) and \( \alpha_L, \alpha_U \neq 0 \) is both necessary and sufficient to have a divergence in the boundary spectrum, and thus a Chern number \( C = \pm 1 \). The states simultaneously fulfilling Eq. (71) and \( \arg \left( \frac{\alpha_L}{\alpha_U} \right) \in \{ 0, \pi, \pm \frac{\pi}{2} \} \), on the other hand, are the transition points between GFPEPS with Chern number \( C = -1 \) and \( C = +1 \).

**C. Symmetries in the considered examples**

We will now study the symmetries in the examples given in Sec. 5 and relate them to chiral edge modes in the light of the results of the previous subsections.

1. **Chern insulator with Chern number \( C = -1 \)**

For the Chern insulator introduced in Sec. 5A we consider only one copy of the two superconductors constituting the Chern insulator. Doing so is trivial on the virtual level, since the matrix \( D \) is block-diagonal with two identical blocks. Each of those blocks has an eigenvalue \( -i \) corresponding to the symmetry
\[
d_1 = -e^{-i \frac{\pi}{2}} c_L - e^{i \frac{\pi}{2}} c_R - ic_U + c_D \quad (79)
\]
for any $\eta \in (0, 1)$. Thus, the state $\Psi_1$ possesses two symmetries, $d_1^{(1,2)}$, with $d_1^{(1)}|\Psi_1\rangle = d_1^{(2)}|\Psi_1\rangle = 0$. Both of them are the form (79), with one containing only the first Majorana operator in left, right, down, up direction and the other only the second Majorana operator.

2. GFPEPS with Chern number $C = 2$

Let us now consider the topological superconductor with Chern number $C = 2$ introduced in Sec. IV.B in the following, all equalities are to be understood up to numerical accuracy. By diagonalizing the CM $D$ of the virtual system, one obtains two linearly independent eigenvectors with eigenvalue $-i$, i.e., there exist two operators $d_1^{(0,1)}$ such that $(x_0d_1^{(0)} + x_1d_1^{(1)})|\Psi_1\rangle = 0$ for all $x_i$. In order to find a basis $d_1^{(\pm)}$ of operators which reveals the symmetries of the model, we start from the state $\Phi_1$ on one column, which has zero modes at momenta $k_y = \pm 1$. We first focus on the symmetry at $k_y = k_y^0 = 1$, where we find that horizontal modes of $\Phi_1$ at momentum $k_y^0$ are annihilated by an operator $\sum_{\kappa=1}^{2} \alpha_{L,\kappa}^{(+)}[c_{L,\kappa}(k_y^0) - ie^{ik_y^0}c_{R,\kappa}(k_y^0)]$ with $k_y^0 = -2.58$ (see Ref. [3] for the values of the $\alpha$’s). This suggests to try to construct a $d_1^{(+)}$ which contains the above operator: it turns out that $x_0d_1^{(0)} + x_1d_1^{(1)}$ indeed contains an operator of this form, which at the same time acts on the vertical modes as $\sum_{\kappa} \alpha_{U,\kappa}^{(+)}[c_{U,\kappa} - ie^{ik_y^0}c_{D,\kappa}]$. We proceed identically for $k_y = -k_y^0 = -1$, and obtain a pair of (non-orthogonal) symmetries

$$d_1^{(\pm)} = \sum_{\kappa=1}^{2} \alpha_{L,\kappa}^{(\pm)}(c_{L,\kappa} - ie^{\pm ik_y^0}c_{R,\kappa}) + \alpha_{U,\kappa}^{(\pm)}(c_{U,\kappa} - ie^{\pm ik_y^0}c_{D,\kappa}).$$

We thus find that also for this model, the existence of divergences in the entanglement spectrum and thus of chiral edge modes is closely related to local symmetries in $\Psi_1$ with the corresponding momenta. Note that since all coefficients $\alpha$ are different, the only way to grow this symmetries following the procedure of Sec. VII.A is to concatenate either exclusively $d_1^{(+)}$ or exclusively $d_1^{(-)}$, which therefore gives rise to maximally entangled Majorana pairs between the two boundaries with definite momenta $\pm k_y^0$ and $\pm k_y^0$, respectively.

3. Generic GFPEPS with Chern number $C = 0$

Let us now consider the non-chiral family of states discussed in Sec. IV.C. As it has only one physical mode, there must be a symmetry $d_1$ such that $d_1|\Psi_1\rangle = 0$. It can be calculated to be

$$d_1 = \frac{2i\sqrt{f(\mu)}}{2 - \mu} c_L + ic_R - \frac{2\sqrt{f(\mu)}}{2 - \mu} c_U + c_D.$$

As it is not of the form Eq. (71) required for chiral edge states, the Chern number of the family is zero.

4. GFPEPS with flat entanglement spectrum and $C = 0$

Let us finally consider the example of Sec. IV.D which has a flat entanglement spectrum. It has a symmetry $d_1|\Psi_1\rangle = 0$ with $d_1 = c_L + c_R - ic_U - ic_D$, i.e., with momentum $k_y^0 = \pm \frac{\pi}{2}$. Since it is not at momentum 0 or $\pi$, there cannot be entangled Majorana modes between the left and the right edge of a long cylinder. However, as the amplitudes are equal, the symmetry is stable under concatenation, and must therefore still be present in an infinite cylinder. The explanation is that in the limit $N \to \infty$, a second symmetry at $k_y^0 = \pm \frac{\pi}{2}$ arises, such that on each edge the two modes at $k_y = \pm \frac{\pi}{2}$ can pair up locally.

D. Symmetry and ground space

The GFPEPS models discussed in this paper appear as ground states of two types of Hamiltonians: On the one hand, there is the flat band Hamiltonian $H_{bb}$, Eq. (5), which by construction has the GFPEPS $\Phi$ as its unique ground state. On the other hand, we can construct the local parent Hamiltonian $H_{ff}$, Eq. (11), which is gapless for the chiral examples considered, i.e., for any finite system size, it is exactly doubly degenerate with energy splittings to higher energies that are the inverse of a polynomial in the system size. In the following, we will show how this ground space can be parametrized by using the virtual symmetry $d_1$ of the local state $\Psi_1$. This is in close analogy to the case of conventional PEPS with topological order, where the ground space can be parametrized by putting loops of symmetry operators on the virtual bonds in horizontal and vertical direction around the torus on which the GFPEPS is defined.

In the following, we will consider the example of Sec. III.B and show how to parametrize its doubly degenerate ground space in terms of strings of symmetry operators. For simplicity, we will set $\lambda = 1/2$. Let us start by recalling Eq. (10), which defines operators $u, w,$ and $d_1$ such that $w|\Psi_1\rangle = w|\Psi_1\rangle = d_1|\Psi_1\rangle = 0$, where $u = \frac{1}{\sqrt{2}}(a - b)$ and $w = \frac{1}{\sqrt{2}}(a + b)$, with $a$ the physical mode, and $b = \frac{1}{\sqrt{2}}(h + v)$, $d_1 = \frac{1}{\sqrt{2}}(-h + v)$, with $h = \exp(i\frac{\pi}{4})(c_L - ic_R)/2$ and $v = (c_U - ic_D)/2$, cf. Eqs. 10 and 11.

Let us now consider a lattice of size $N_h \times N_v$, and concatenate all the $\Psi_1$ in this region by projecting onto $\langle \omega \rangle_{jn}$ and $\langle \omega' \rangle_{jn}$ on all the horizontal and vertical links, respectively, but without closing either of the boundaries, resulting in a state $\Psi_{N_h \times N_v}$. Following the arguments given in Sec. VII.A projecting onto the maximally entangled states concatenates the symmetry operators $u, w$ and $d_1$, which gives rise to three symmetries for the
square region,
\[ \tilde{u}|\Psi_{N_h \times N_v}\rangle = \tilde{u}|\Psi_{N_v \times N_h}\rangle = \tilde{d}_1|\Psi_{N_h \times N_v}\rangle = 0, \]
where
\[ \tilde{u} = \frac{1}{\sqrt{2}}(\tilde{a}^\dagger - \tilde{b}), \quad \tilde{\omega} = \frac{1}{\sqrt{2}}(\tilde{a} + \tilde{b}^\dagger), \quad \tilde{d}_1 = \frac{1}{\sqrt{2}}(-\tilde{\omega} + \tilde{v}), \]
where again
\[ \tilde{b} = \frac{1}{\sqrt{2}}(\tilde{h} + \tilde{v}), \]
\[ \tilde{h} = \frac{1}{\sqrt{2}}e^{\frac{i}{2}(\tilde{c}_L - i\tilde{c}_R)} \text{ and } \tilde{v} = \frac{1}{\sqrt{2}}(\tilde{c}_U - i\tilde{c}_D). \]

Here, \( \tilde{c}_p = \sum_y c_{y,p}, \tilde{c}_q = \sum_x c_{x,q} \) \((p = L, R, q = U, D)\) are the zero-momentum (center of mass) mode of the virtual Majorana modes on the corresponding boundary, and \( \tilde{a} = \sum_j a_j \) is the center-of-mass mode of the physical fermion (with site index \( j \)).

In order to close the boundary, we first transform the entangled states across the boundary into the Fourier basis (since they are translational invariant, they are of the same form in \( k \)-space), and project onto all entangled states at the boundary except those with momentum \( k_x = 0 \) and \( k_y = 0 \). This leaves us with the zero-momentum part of the state \( \tilde{\Psi}_{N_h \times N_v} \), which we denote by \( \tilde{\Psi}_{N_h \times N_v} \), where we disregard additional physical modes which are unentangled to the boundary degrees of freedom. This state is exactly characterized by the three symmetries of Eq. (82a), and thus
\[ \tilde{\Pi}_{N_h \times N_v} = \langle \tilde{\Psi}_{N_h \times N_v} | \langle \tilde{\Psi}_{N_h \times N_v} | = \tilde{d}_1 d_1^\dagger \tilde{a}^\dagger \tilde{w} \tilde{a}^\dagger, \]
\[ = 4\tilde{d}_1 d_1^\dagger (\tilde{a}^\dagger - \tilde{b})(\tilde{a} + \tilde{b}^\dagger)(\tilde{a}^\dagger + \tilde{b}) \]
\[ = \frac{1}{2} \left( \tilde{d}_1^\dagger (-\tilde{a}^\dagger \tilde{b} + a^\dagger \tilde{b}^\dagger + b^\dagger \tilde{a}^\dagger + \tilde{a} b) \right). \]

Following Eq. (87), the projection onto the remaining zero momentum bonds is \( \tilde{\omega}_h = \frac{1}{\sqrt{2}}(1 + i\tilde{c}_D \tilde{c}_U) \) and \( \tilde{w} = \frac{1}{\sqrt{2}}(1 + i\tilde{c}_D \tilde{c}_U) \). Hence, \( \tilde{h}^\dagger |\tilde{\omega}_h\rangle = \tilde{b}^\dagger |\tilde{\omega}_h\rangle = 0 \), and thus, using Eqs. (82c) and (83), also \( d_1^\dagger |\tilde{\omega}_h\rangle, \tilde{\omega}_v\rangle = \tilde{b}^\dagger |\tilde{\omega}_h\rangle, \tilde{\omega}_v\rangle = 0 \), i.e.,
\[ |\tilde{\omega}_h\rangle, \tilde{\omega}_v\rangle = d_1^\dagger b^\dagger |\Omega_{\text{vir}}\rangle \]
(48)
(with \( |\Omega_{\text{vir}}\rangle \) the vacuum of \( \tilde{d}_1 \) and \( \tilde{b} \), or equivalently of \( \tilde{h} \) and \( \tilde{v} \); the phase can be absorbed in \( |\Omega_{\text{vir}}\rangle \)).

Let us now see what happens when we close the remaining \((k_x, k_y) = (0, 0)\) boundary. Since \( \tilde{\Pi}_{N_h \times N_v} \) is proportional to \( \tilde{d}_1^\dagger d_1^\dagger \), we find that
\[ \langle \tilde{\omega}_h, \tilde{\omega}_v | \tilde{\Pi}_{N_h \times N_v} | \tilde{\omega}_h, \tilde{\omega}_v \rangle = 0 \]
- the success probability for constructing the GFPEPS by projecting onto entangled states is zero! Indeed, this comes as no surprise, since the success probability of any such projection is related to \( \sqrt{\det(D + \omega^{-1})} \) in Eq. (68), which in turn is the square root of the spectral function of the parent Hamiltonian as constructed in Ref. (22) (which generally, and in particular for the example considered, is equal to \( \mathcal{H}_g \)). Having a gapless parent Hamiltonian requires the GFPEPS to vanish when performing the projections. This raises the question of how to obtain a proper PEPS description of the ground state subspace.

Fortunately, this problem can be overcome exactly by using the virtual symmetry of \( \Psi_1 \). To this end, let us place a string of symmetry operators
\[ \tilde{c}_L = \frac{1}{\sqrt{2}} e^{\frac{i}{2}\pi} (\tilde{d}_1^\dagger + \tilde{b}) + \frac{1}{\sqrt{2}} e^{\frac{i}{2}\pi} (-\tilde{d}_1^\dagger + \tilde{b}) \]
at the left edge before closing the boundary, i.e., we replace the state \( |\tilde{\omega}_h, \tilde{\omega}_v\rangle = d_1^\dagger b^\dagger |\Omega_{\text{vir}}\rangle \) by
\[ |\tilde{\omega}_L\rangle = \tilde{c}_L |\tilde{\omega}_h, \tilde{\omega}_v\rangle = \frac{1}{\sqrt{2}} e^{\frac{i}{2}\pi} (\tilde{b}^\dagger + d_1^\dagger) |\Omega_{\text{vir}}\rangle. \]

Using that \( \tilde{\Pi}_{N_h \times N_v} \) is proportional to \( \tilde{d}_1 d_1^\dagger \), this immediately yields
\[ \langle \tilde{\omega}_L | \tilde{\Pi}_{N_h \times N_v} | \tilde{\omega}_L \rangle = \frac{1}{\sqrt{2}} |\tilde{\Omega}_{\text{vir}}\rangle \tilde{c}_L |\tilde{\Omega}_{\text{vir}}\rangle = \frac{1}{\sqrt{2}} \tilde{c}_L \tilde{c}_L \]
\[ \text{vac} = \langle \tilde{\omega}\rangle |\tilde{\Omega}_{\text{vir}}\rangle \tilde{c}_L |\tilde{\Omega}_{\text{vir}}\rangle = \langle \tilde{\omega}\rangle |\tilde{\Omega}_{\text{vir}}\rangle \]
\[ = |\tilde{\Phi}_{\text{C}_h}\rangle \]
eq, where we defined \( |\tilde{\Psi}\rangle \) as the state of all virtual and physical particles before any projection is applied, and \( \langle \tilde{\omega}\rangle \) denotes the projection on all virtual modes.

Let us now finally see what happens if we insert both a horizontal and a vertical string: Then, we must replace \( |\tilde{\omega}_h, \tilde{\omega}_v\rangle \) by
\[ |\tilde{\omega}_L, \tilde{\omega}_L\rangle = \tilde{c}_L \tilde{c}_L |\tilde{\omega}_h, \tilde{\omega}_v\rangle = e^{-i\pi/4} |\Omega_{\text{vir}}\rangle, \]
and we find
\[ \langle \tilde{\omega}_L | \tilde{\Pi}_{N_h \times N_v} | \tilde{\omega}_L \rangle = \langle \Omega_{\text{vir}} | \tilde{\Pi}_{N_h \times N_v} | \Omega_{\text{vir}} \rangle = \frac{1}{\sqrt{2}} \tilde{c}_L \tilde{c}_L, \]
which is the second ground state, where the gapless center-of-mass mode is in the vacuum.

Note that the second ground state can equivalently be obtained using that \( \tilde{a} |\tilde{\Psi}_{N_h \times N_v}\rangle = -\tilde{b} |\tilde{\Psi}_{N_h \times N_v}\rangle \)
[Eq. (82b)], which exactly cancels the \( \tilde{b} \) in Eq. (83), and thus yields Eq. (87).
In summary, we find that it is possible to parametrize the two-dimensional ground state subspace of the model using the string operators given by the virtual symmetry of $\Psi_1$: One of the ground states is obtained by inserting a single string (either horizontally or vertically), while the other ground state is obtained by inserting both a horizontal and a vertical string.

VII. CONCLUSIONS AND OUTLOOK

In this paper, we have established a framework for boundary and edge theories for Gaussian fermionic Projected Entangled Pair States (GFPEPS), and applied it to the study of chiral fermionic PEPS, and in particular their underlying symmetry structure.

We have introduced two different kinds of Hamiltonians, the boundary Hamiltonian $H_N^b$ and the edge Hamiltonian $H_N^e$. The former reproduces the entanglement spectrum of the reduced density matrix of a region as a thermal state $\exp(-H_N^b)$, while the latter contains the low energy physics of the truncated flat band Hamiltonian $H_n$. We have shown that in the context of GFPEPS, both of these Hamiltonians act on the auxiliary degrees of freedom at the boundary, which naturally imposes a one-dimensional structure, and that they are related in a simple way. As the physical edge modes corresponding to $H_N^e$ are localized at the same edge of a cylinder, the number of chiral edge modes and thus the Chern number of a GFPEPS can be read off the virtual boundary and edge Hamiltonian. We have also provided constructive methods for analytically and numerically determining $H_N^b$ and $H_N^e$ for general GFPEPS, and in particular on infinite cylinders and tori.

We have subsequently provided a full analysis of the edge and boundary Hamiltonian for the case of GFPEPS with one Majorana mode per bond, $\chi = 1$. We have put particular emphasis on the case of GFPEPS with chiral edge modes, where we have shown that the presence of chiral edge modes is equivalent to a maximally entangled state between the virtual Majorana modes at the two boundaries of a cylinder, which leads to a divergence in the entanglement spectrum at the corresponding momentum. Subsequently, we have related this global virtual symmetry in the GFPEPS to a local virtual symmetry in the PEPS tensor $\Psi_1$. Identifying such symmetries has proven extremely powerful in the case of non-chiral topological models, where it has allowed for a comprehensive understanding of ground state degeneracy, topological entropy, excitations, and more from a simple local symmetry and the strings formed by it. We have shown that the virtual symmetry of chiral GFPEPS is similarly powerful, as it explains the origin of chiral edge modes, the topological correction to the Rényi entropy; and it allows to parametrize the ground state space of the gapless parent Hamiltonian using strings formed by the symmetry. It is an interesting question to understand further implications of the symmetry, such as the excitations obtained from open strings, or the role played by symmetries for fermionic PEPS with higher bond dimension $\chi$. Our numerical results indeed suggest that the same type of symmetries underlies chiral edge modes for $\chi > 1$.

Understanding the local symmetries underlying chiral topological order is of particular interest when going to interacting models, since these local symmetries will still give rise to maximally entangled Majorana modes between distant edges even for interacting models; keeping the symmetry structure of the local PEPS tensor untouched thus seems to be a crucial ingredient when adding interactions. This can in particular be achieved by taking several copies of a chiral GFPEPS and coupling the copies on the physical level without changing the auxiliary modes, for instance by a Gutzwiller projection (cf. Ref. 24), similar to the way in which fractional Chern insulators are constructed; we are currently pursuing research in this direction.

Appendix A: Decay of correlations in real space

In this part of the Appendix we show that the correlations of the GFPEPS defined via Eq. (12) and therefore also the hoppings of the corresponding flat band Hamiltonian $H_b$, in Eq. (10) decay like the inverse of the distance cubed. More precisely, we will show that the $d_j(k)$ in Eq. (10) $(j = x, y)$ decay at least as fast as $\frac{\log(|r|)}{|r|}$, but not faster than $\frac{1}{|r|^2}$ in real space (by analogous arguments it can be shown that $d_j(k)$ corresponds to a faster decay than the inverse distance cubed). Crudely speaking, the reason for this decay is that the $d_j(k)$ have a non-analytical point at $k = (0, 0)$, where they are continuous, but not continuously differentiable.
An important fact which we will need in the proof is the following relation between the decay of Fourier coefficients and the smoothness of the corresponding Fourier series, stated for the relevant case of two dimensions: Given that the Fourier coefficients decay faster than \(|r|^{-(2+d)}\) (i.e., they are upper bounded by a constant times \(|r|^{-(2+d+\delta)}\) for some \(\delta > 0\)), it follows that the Fourier series is \(d\) times continuously differentiable (continuous if \(d = 0\)); see, e.g., Proposition 3.2.12 in Ref. [34].

Let us start by considering the behavior of \(d(k)\) around the non-analytical point \(k = (0,0)\). For simplicity, we again restrict ourselves to \(\lambda = 1/2\), but the arguments for other \(\lambda\) are the same. We expand the numerators and denominators in Eqs. [13] and [19] to second order and those in Eq. [20] to fourth order around \(k = (0,0)\) to obtain

\[
\hat{d}_x(k) = \frac{-2k_xk_y^2}{k_x^2+k_y^2} + O(k^2), \quad \text{(A1)}
\]

\[
\hat{d}_y(k) = \frac{2k_x^2k_y}{k_x^2+k_y^2} + O(k^2), \quad \text{(A2)}
\]

\[
\hat{d}_z(k) = -1 + \frac{2k_x^2k_y^2}{k_x^2+k_y^2} + O(k^3). \quad \text{(A3)}
\]

This shows that the \(\hat{d}_{x,y}(k)\) are continuous, but not continuously differentiable at \(k = (0,0)\), whereas \(\hat{d}_z(k)\) is both (and only its second derivative is non-continuous). This implies that the \(\hat{d}_{x,y}\) cannot asymptotically decay faster than \(1/|k|^3\) in real space, since otherwise their Fourier transform would be continuously differentiable. This demonstrates the claimed lower bound bound on the decay of the correlations.

The upper bound is obtained by formally carrying out the Fourier transform and bounding the terms obtained after partial integration: To simplify notation we suppress the index \(x\) or \(y\) in \(\hat{d}_{x,y}(k)\), respectively (the result applies to both of them and also to the overall hopping amplitude of the Hamiltonian). Let us assume that the site coordinates fulfill \(|x| \geq |y| (x \neq 0)\); in the opposite case the line of reasoning is the same. We integrate its Fourier transform twice with respect to \(k_x\) by parts, \((r = (x, y))\)

\[
d_r = \int_{\text{BZ}} \hat{d}(k)e^{-ik\cdot r}dk_xdk_y = \left(-\frac{1}{|x|^2}\right)^2 \int_{-\pi}^{\pi} dk_y \int_{-\pi}^{\pi} dk_x e^{-ik\cdot r} \hat{d}_x(k), \quad \text{(A4)}
\]

where BZ denotes the first Brillouin zone, that is, \((-\pi, \pi) \times (-\pi, \pi)\). Let us first show that the last double integral is defined, although its integrand might diverge at \(k = (0,0)\). For that, we will demonstrate the bounds

\[
\left| \frac{\partial^2 \hat{d}(k)}{\partial k_x^2} \right| < \frac{c}{|k|}, \quad \left| \frac{\partial^4 \hat{d}(k)}{\partial k_x^3} \right| < \frac{c'}{|k|^2}. \quad \text{(A5)}
\]

with \(c, c' > 0\). In order to show the first bound, we realize that \(\frac{\partial^2 \hat{d}(k)}{\partial k_x^2} \sqrt{k_x^2 + k_y^2}\) and \(\frac{\partial^4 \hat{d}(k)}{\partial k_x^3} (k_x^2 + k_y^2)\) cannot diverge anywhere but at \(k = (0,0)\). We expand them for \(\hat{d}(k) = \hat{d}_x(k)\) around this point by setting \(k = (|k| \cos(\phi), |k| \sin(\phi))\) and obtain

\[
\frac{\partial^2 \hat{d}(k)}{\partial k_x^2} \sqrt{k_x^2 + k_y^2} \to \frac{-4(\cos(3\phi) \sin^2(\phi)) + O(|k|)}{1 + O(|k|)}, \quad \text{(A6)}
\]

\[
\frac{\partial^4 \hat{d}(k)}{\partial k_x^3} (k_x^2 + k_y^2) \to \frac{12(4\phi) \sin^2(\phi) + O(|k|)}{1 + O(|k|)}. \quad \text{(A7)}
\]

Therefore, the limit \(|k| \to 0\) exists for all \(\phi\) and is uniformly bounded, and as a result, the expressions on the left hand side of Eqs. [A6] and [A7] are bounded for any \(k \in \text{BZ}\). The same thing is encountered for \(\hat{d}(k) = \hat{d}_y(k)\). Since the left hand sides of Eqs. [A6] and [A7] do not diverge for any \(k\) and are defined for a finite region (the first Brillouin zone), the bounds [A4] are correct. The first bound implies that the double integral [A4] is defined (and finite).

It will be convenient to split the integral [A4] into two parts, one with range over the full circle \(C_{\epsilon}\) center at \(k = (0,0)\) and the rest. The first part is bounded in absolute value by \(\int_{C_{\epsilon}} \frac{1}{(2\pi)^2} dk = 2\pi \epsilon c\). Thus, employing another partial integration

\[
|d_r| < \frac{2\pi \epsilon c}{x^2} + \frac{1}{x^2} \left| \int_{\text{BZ}} \frac{\partial^2 \hat{d}(k)}{\partial k_x^2} e^{-ik\cdot r} dk \right| \quad \text{(A8)}
\]

\[
= \frac{2\pi \epsilon c}{x^2} + \frac{1}{x^2} \left[ \left( \frac{1}{-i\cdot x} \right) \left( \int_{-\pi}^{\pi} \hat{d}_y(k) \frac{\partial^2 \hat{d}(k)}{\partial k_x^2} e^{-ik\cdot r} dk \right) \right] \quad \text{(A9)}
\]

\[
\times \left( \epsilon - k_y^2 \right) - \int_{\text{BZ}} \frac{\partial^3 \hat{d}(k)}{\partial k_x^3} e^{-ik\cdot r} dk \right| \quad \text{(A10)}
\]

We use the bounds on the second and third derivative of \(\hat{d}(k)\),

\[
|d_r| < \frac{2\pi \epsilon c}{x^2} + \frac{1}{|x|^3} \left| \int_{\text{BZ}} \frac{\partial^3 \hat{d}(k)}{\partial k_x^3} e^{-ik\cdot r} dk \right| \quad \text{(A11)}
\]

We now set \(\epsilon = \frac{1}{|x|^2}\) to obtain

\[
|d_r| < \frac{2\pi(2c + c' \ln(\sqrt{2\pi} - \ln(\epsilon)))}{|x|^3}. \quad \text{(A11)}
\]
After realizing that \(|x| \geq \frac{|r|}{v_f}\), this leads to

\[|d_r| < \frac{a + b \ln(|r|)}{|r|^2} \quad (A12)\]

(a, b > 0). The decay of \(d_z\) in real space is faster, since its derivatives start diverging at a higher order. Hence, the hoppings decay at least as fast as \(\frac{|r|}{|r|^2}\) and, therefore, for large \(|r|\) as the inverse distance cubed.

Appendix B: Momentum polarization and topological entanglement entropy

In this Appendix, we derive analytical expressions for two quantities which probe topological order based on the entanglement spectrum, namely the momentum polarization and the topological entanglement entropy. First, we will prove that the universal contribution to the momentum polarization \(d_z\) is exactly determined by the number of divergences in the entanglement spectrum (\(R^2_N(k_\nu)\) in the case of GFPEPS); and second, we will prove that there is no additive topological correction to the von Neumann entropy \(S_{\text{VN}}\) of the entanglement spectrum. Let us stress that both of these arguments rely only on few properties of the entanglement spectrum and the corresponding boundary Hamiltonian, and are thus not restricted to the case of GFPEPS.

Both these proofs are based on the Euler-Maclaurin formulas, which for our purposes say the following: Given a function \(f : [0, 2\pi] \to \mathbb{C}\) which is 3 times continuously differentiable, it holds that

\[
\sum_{k=0}^{N} f\left(\frac{2\pi k}{N}\right) - \frac{f(0) + f(2\pi)}{2} = \frac{N}{2\pi} \int_0^{2\pi} f(x) \, dx + \frac{2\pi f'(2\pi) - f'(0)}{12 N} + O(1/N^3),
\]

(B1)

\[
\sum_{k=1}^{N} f\left(\frac{\pi(2k-1)}{N}\right) = \frac{N}{2\pi} \int_0^{2\pi} f(x) \, dx - \frac{2\pi f'(2\pi) - f'(0)}{24 N} + O(1/N^3).
\]

(B2)

Let us now first discuss how to compute the momentum polarization; for clarity, we will focus on two copies of the superconductor defined in Sec. II B but the arguments can be readily adapted. For a state \(|\varphi\rangle\) on a long cylinder which is partitioned into two cylinders \(A\) and \(B\), the momentum polarization \(d_z\) is \(\mu(n) = \langle \varphi | T_A | \varphi \rangle\), where \(T_A\) translates part \(A\) of the system around the cylinder axis, and \(N_c\) is the circumference of the cylinder; and it is expected to scale as \(\exp[-\alpha N_v + \frac{2\pi}{N_v}(h_a - \frac{\pi}{4})]\), where \(c\) is the chiral central charge and \(h_a\) the topological spin, and \(\alpha \in \mathbb{C}\) is non-universal. It is immediate to see that this definition is equivalent to evaluating \(\mu(N_v) = \sum_{\ell} \lambda_{\ell} e^{ik\ell}\), where \(\lambda_{\ell}\) is the entanglement spectrum of \(A\), i.e., \(|\varphi\rangle = \sum_{\ell} \sqrt{\lambda_{\ell}} |\varphi^A_{\ell}\rangle|\varphi^B_{\ell}\rangle\), and \(k_{\ell}\) is the momentum of \(|\varphi^A_{\ell}\rangle\). In PEPS, the entanglement spectrum corresponds to a state on the boundary degrees of freedom, and therefore this expression can be evaluated directly at the boundary. Concretely, in the case of two states with one fermion per bond (i.e., \(\chi = 2\)), such as two copies of the superconductor of Sec. II B, the entanglement spectrum corresponds to the thermal state of the non-interacting Hamiltonian \(H_N^b\), so that the momentum polarization is given by

\[
\log(\mu(N_v)) = \sum_{\ell} \log \frac{e^{-\omega_{\ell} + ik + \omega_{\ell}}}{e^{-\omega_{\ell} + ik + \omega_{\ell}}} =: f(k),
\]

(B3)

where \(\omega_{\ell}\) is the energy of the boundary mode with momentum \(k = k_{\ell}\), as shown in Fig. 7. To evaluate the sum \(\sum_{\ell} f(k_{\ell})\), we use the Euler-Maclaurin formulas, where \(f(k)\) is defined via the summand in (B3) on the open interval \((0, 2\pi)\), and continuously extended to \([0, 2\pi]\). In order to ensure continuity of \(f\), we follow the different branches of the logarithm (i.e., we add \(2\pi i\) as appropriate). Moreover, for examples with a gapless mode at \(k = \pi\) (such as the examples of Sec. II B), \(f(k)\) diverges, which can be fixed by replacing \(e^{ik}\) by \(e^{2ik}\) above (and subsequently correcting for the factor of 2 obtained in the scaling). For the examples considered, the functions \(f\) obtained this way are indeed 3 times continuously differentiable. Which of the two Euler-Maclaurin equations we use depends on whether the sum in (B3) runs over \(k = 2\pi n/N_v\) or \(k = 2\pi (n + 1)/N_v\) (\(n = 0, \ldots, N_v - 1\), which is connected to the choice of boundary conditions. We will focus on the case \(k = 2\pi (n + 1)/N_v\), but let us note that the difference in the relevant subleading terms is merely a factor of \(-2\) in the \(1/N_v\) term (which in the examples relates to a non-zero topological spin \(h_a\)) and a trivial additive term proportional to \(f(2\pi) - f(0)\) which relates to the treatment of the branches of the logarithm.

With this choice of \(k\), using (B2) we find that

\[
\log \mu(N_v) = \alpha N_v - \frac{2\pi i}{N_v} \tau + O(1/N_v^3),
\]

where \(\alpha = \frac{1}{2\pi} \int f(x) \, dx\) is non-universal, and \(\tau = \frac{\omega_{k_{\ell}}}{2\pi}\) is the energy of the boundary mode with momentum \(k_{\ell}\) at \(\omega_{k_{\ell}}\). For the examples considered, the functions \(f\) obtained this way are indeed 3 times continuously differentiable. Which of the two Euler-Maclaurin equations we use depends on whether the sum in (B3) runs over \(k = 2\pi n/N_v\) or \(k = 2\pi (n + 1)/N_v\) (\(n = 0, \ldots, N_v - 1\), which is connected to the choice of boundary conditions. We will focus on the case \(k = 2\pi (n + 1)/N_v\), but let us note that the difference in the relevant subleading terms is merely a factor of \(-2\) in the \(1/N_v\) term (which in the examples relates to a non-zero topological spin \(h_a\)) and a trivial additive term proportional to \(f(2\pi) - f(0)\) which relates to the treatment of the branches of the logarithm.
\( f'(k_0) = \lim_{k \to k_0} \left[ i \frac{e^{2\omega_k}}{1 + e^{2\omega_k}} + O(k - k_0) \right] \)

and thus a divergence in the entanglement spectrum at \( k_0 = 0 \), such as for the example of Sec. II B implies that \( f'(2\pi) - f'(0) = \pm i \). We thus find that \( \tau \) is universal, with its value only depending on the presence of a divergence in the entanglement spectrum, but not on the exact form of \( \omega_k \). In particular, with \( \tau = e/24 \), we find a chiral central charge of \( c = 1 \) for two copies of the superconductor, which amounts to \( c = 1/2 \) for a single copy of the topological superconductor. Note that the Euler-MacLaurin formulas can be easily adapted to deal with more discontinuities and with different values of \( k \), by expanding \( f(k) \) in terms of Bernoulli polynomials; thus, the outlined approach allows for the analytical calculation of the momentum polarization for general free fermionic systems with several boundary modes and arbitrary fluxes through the torus.

Let us conclude by discussing the scaling of the topological entropy, which is given by \( S_{\text{N}}(N_v) = \sum_k g(k) \), \( g(k) = -p_k \log p_k + (1 - p_k) \log (1 - p_k), \) \( p_k = e^{-\omega_k}/(e^{-\omega_k} + e^{2\omega_k}) \) (in particular, \( g(k) \to 0 \) for \( k \to 0, 2\pi \)).

For the cases discussed in the paper, \( g(k) \) is continuous and periodic, but its second derivative diverges; thus, the error term in the Euler-MacLaurin formula can be of order \( o(1/N_v) \). Yet, this is sufficient as we are only interested in constant corrections to the entanglement entropy, and one immediately finds that both for periodic and anti-periodic boundary conditions, \( S_{\text{N}}(N_v) = a N_v + o(1/N_v) \), with a non-universal \( a = \frac{1}{2\pi} \int_{0}^{2\pi} g(k) \, dk \), and no constant topological correction.

Appendix C: Polynomial decay of the boundary Hamiltonian hoppings

In this part of the Appendix, we prove that the hopping amplitudes \( |\langle H_R^{\infty}\rangle_{1,1+y} \rangle \) of the boundary Hamiltonian of the example of Sec. II B shown in Fig. 13 decay as \( \log(y)/y \).

We start by calculating the single-particle entanglement spectrum on the right boundary: For that we employ Eq. 15 to calculate \( D_1(k_y) \) for the topological superconductor defined by Eq. 12 and from it \( \hat{\Sigma}^R_\infty(k_y) \) via Eq. 65 as a function of \( \lambda \). The result is

\[
\hat{\Sigma}^R_\infty(k_y) = i \frac{2\lambda^2 \sin(k_y)}{\sqrt{\sigma^2(k_y)} + 4\lambda^4 \sin^2(k_y)}
\]

with \( g(k_y) \) some second order polynomial in \( \cos(k_y) \). For \( \lambda \neq 0 \) this function is analytic as long as \( k_y \) is not an integer multiple of \( \pi \). One can check that \( g(\pi) \neq 0 \) for any \( \lambda \in (0,1) \), so \( \hat{\Sigma}^R_\infty(k_y) = 0 \) and the only non-analytical point is \( k_y = 0 \). As shown in Sec. V these are the only \( k_y \)-points where \( |\hat{\Sigma}^R_\infty(k_y)| = 1 \) is possible and where hence the spectrum of the boundary Hamiltonian can diverge: One can check from the explicit function \( g(k_y) \) that \( g(\delta k_y) = g(-\delta k_y) = g_0 \delta k_y^2 (1 + O(\delta k_y^2)) \) for \( \lambda \in (0,1) \) (where \( g_0 \) depends on \( \lambda \)). Therefore,

\[
\hat{\Sigma}^R_\infty(\delta k_y) = i \frac{2\lambda^2 \delta k_y}{\sqrt{\sigma^2(\delta k_y) + 4\lambda^4 \delta k_y^2}} + 4\lambda^4 \delta k_y^2
\]

\[
= i \left( 1 - \frac{g_0^2}{8\lambda^4(2\lambda)^2} \delta k_y^2 (1 + O(\delta k_y^2)) \right) \text{sgn}(\delta k_y)
\]

Owing to Eq. 22 for \( N \to \infty \), the single-particle spectrum is given by

\[
-i \hat{H}^R_\infty(k_y) = \ln \left( \frac{1 - \hat{\Sigma}^R_\infty(k_y)}{1 + i \hat{\Sigma}^R_\infty(k_y)} \right)
\]

Henceforth, we can expand

\[
-i \hat{H}^R_\infty(\delta k_y) = \left[ \ln \left( \frac{16\lambda^2 (2 - \lambda)^4}{g_0^2} \right) \right] - 2\ln(\delta k_y)

- \ln(1 + O(\delta k_y^2)) \text{sgn}(\delta k_y),
\]

and we see that the non-analyticity is only due to the term \( 2\ln(\delta k_y) \), the other ones being analytical around \( k_y = 0 \).

The Fourier coefficients of an analytical function defined on \((\pi, -\pi)\) decay exponentially. Thus, the algebraic decay of \( |\langle H_R^{\infty}\rangle_{1,1+y} \rangle \) is due to the diverging term we singled out,

\[
|\langle H_R^{\infty}\rangle_{1,1+y} \rangle \underset{y \to \infty}{\to} \frac{4}{\sqrt{N_v}} \int_{0}^{\pi} \sin(k_y y) \ln(k_y) dk_y

\underset{y \to \infty}{\to} \frac{4}{\sqrt{N_v}} \left[ \frac{\log(y)}{y} + O \left( \frac{1}{y} \right) \right]
\]

with the prefactor of the \( 1/y \) contribution being depending on whether \( y \) is even or odd but constant otherwise.

17. The name Majorana mode is not really appropriate, as two of them define a single (fermionic) mode. Nevertheless, we will use such a nomenclature here.
18. The motivation for the name “maximally entangled Majorana modes” comes from the following construction (see Ref. 25): One can add an extra Majorana operator per bond such that each bond is represented by a full fermionic mode. In that case, the state generated by ω_{j,n} out of the vacuum is an entangled state between the two fermionic modes along that bond (for the formal definition of entangled fermionic modes, see Ref. 30). The extra Majorana operators do not play any role as long as antiperiodic boundary conditions are imposed on them, and can thus be ignored so that one ends up with the states as we are using them throughout this article.
