Abstract. Let \( P f(x) = -if'(x) \) and \( Qf(x) = xf(x) \) be the canonical operators acting on an appropriate common dense domain in \( L^2(\mathbb{R}) \). The derivations \( D_P(A) = i(PA - AP) \) and \( D_Q(A) = i(QA - AQ) \) act on the \( * \)-algebra \( A \) of all integral operators having smooth kernels of compact support, for example, and one may consider the noncommutative “Laplacian” \( L = D_P^2 + D_Q^2 \) as a linear mapping of \( A \) into itself.

\( L \) generates a semigroup of normal completely positive linear maps on \( B(L^2(\mathbb{R})) \), and we establish some basic properties of this semigroup and its minimal dilation to an \( E_0 \)-semigroup. In particular, we show that its minimal dilation is pure, has no normal invariant states, and in section 3 we discuss the significance of those facts for the interaction theory introduced in a previous paper.

There are similar results for the canonical commutation relations with \( n \) degrees of freedom, \( 1 \leq n < \infty \).

1. Discussion, basic results.

Consider the canonical operators \( P, Q \) acting on an appropriate common dense domain in \( L^2(\mathbb{R}) \)

\[
P = \frac{1}{i} \cdot \frac{d}{dx},
Q = \text{multiplication by } x.
\]

These operators can be used to define unbounded derivations (say on the dense \( * \)-algebra \( A \) of all integral operators having kernels which are smooth and of compact support) by

\[
D_P(X) = i(PX - XP), \quad D_Q(X) = i(QX - XQ), \quad X \in A.
\]

Thinking of these derivations as noncommutative counterparts of \( \partial/\partial x \) and \( \partial/\partial y \) we define a “Laplacian” \( L : A \to A \) by

\[
L = D_P^2 + D_Q^2.
\]
Throughout this paper we will use the term CP semigroup to denote a semigroup $\phi = \{\phi_t : t \geq 0\}$ of normal completely positive linear maps on the algebra $B(H)$ of all bounded operators on a separable Hilbert space $H$, which preserves the unit $\phi_t(1) = 1$, and which is continuous in the natural sense (namely $\langle \phi_t(A)\xi,\eta \rangle$ should be continuous in $t$ for fixed $\xi, \eta \in H$ and $A \in B(H)$). The purpose of this section is to exhibit concretely a CP semigroup whose generator can be identified with the operator mapping $L$ of (1.1) (see Theorem 1.10).

Let $U_t = e^{itQ}$, $V_t = e^{itP}$ be the two unitary groups associated with $Q$, $P$,

$$U_t f(x) = e^{itx} f(x), \quad V_t f(x) = f(x + t), \quad f \in L^2(\mathbb{R}).$$

These two groups satisfy the Canonical Commutation Relations $V_t U_s = e^{ist} U_s V_t$ for $s, t \in \mathbb{R}$. It is more convenient to make use of the CCRs in Weyl’s form. For every $z = (x, y) \in \mathbb{R}^2$ the Weyl operator

$$W_z = e^{ixy} U_x V_y$$

is unitary, it is strongly continuous in $z$, and it satisfies the Weyl relations

$$W_{z_1} W_{z_2} = e^{i\omega(z_1, z_2)} W_{z_1 + z_2}$$

where $\omega$ is the symplectic form on $\mathbb{R}^2$ given by

$$\omega((x, y), (x', y')) = \frac{1}{2} (x'y - xy').$$

A strongly continuous mapping $z \mapsto W_z \in B(H)$ into the unitary operators on some Hilbert space $H$ which satisfies (1.3) is called a Weyl system. It is well known that the Weyl system (1.2) is irreducible, and hence the space of all finite linear combinations of the $W_z$ is a unital strongly dense $\ast$-subalgebra of $B(L^2(\mathbb{R}))$. The Stone-von Neumann theorem implies that every Weyl system is unitarily equivalent to a direct sum of copies of the concrete Weyl system (1.2).

Proceeding heuristically for a moment, let $D_P$ and $D_Q$ be the derivations above. After formally differenting the relation $V_t U_s = e^{ist} U_s V_t$ we find that

$$D_P(U_x) = ixU_x, \quad D_P(V_y) = 0,$$

$$D_Q(U_x) = 0, \quad D_Q(V_y) = iyU_y,$$

hence the action of $L = D_P^2 + D_Q^2$ on the Weyl system (1.2) is given by

$$L(W_z) = -(x^2 + y^2) W_z = -|z|^2 W_z, \quad z = (x, y) \in \mathbb{R}^2.$$

After formally exponentiating we find that for $t \geq 0$ the operator mapping $\phi_t = \exp(tL)$ for $t \geq 0$ can be expected to satisfy

$$\phi_t(W_z) = e^{-t|z|^2} W_z, \quad z \in \mathbb{R}^2, t \geq 0.$$

Remarks. A number of authors have considered completely positive semigroups defined on a Weyl system by formulas such as (1.5), using techniques similar to those of Proposition 1.7 below (see pp. 128-129 of [3], or [6] for two notable examples).
We include a full discussion of these basic issues since in section 3 we require details of the construction that are not easily found in the literature.

We also remark that virtually all of the results below have straightforward generalizations to the case in which \( P, Q \) are replaced with the canonical operators \( P_1, \ldots, P_n, Q_1, \ldots, Q_n \) associated with \( n \) degrees of freedom. Indeed, the generalization amounts to little more than a reinterpretation of notation. On the other hand, while Proposition 1.7 remains valid (with the same proof) for infinitely many degrees of freedom (c.f. [3] loc cit), we do not know if that is the case for the more precise results of section 3.

In order to define the CCR heat flow rigorously we take (1.5) as our starting point and deduce the existence of the semigroup and its basic properties from the following general result. Consider the Banach space \( M(\mathbb{R}^2) \) of all complex-valued measures \( \mu \) on \( \mathbb{R}^2 \) having finite total variation \( \| \mu \| \). \( M(\mathbb{R}^2) \) is a commutative Banach algebra with unit relative to the usual convolution of measures

\[
\mu \ast \nu(S) = \int_{\mathbb{R}^2 \times \mathbb{R}^2} \chi_S(z + w) \, d\mu(z) \, d\nu(w).
\]

It will be convenient to define the Fourier transform of a measure \( \mu \in M(\mathbb{R}^2) \) in terms of the symplectic form \( \omega \) of (1.4)

\[
(1.6) \quad \hat{\mu}(\zeta) = \int_{\mathbb{R}^2} e^{i\omega(\zeta, z)} \, d\mu(z).
\]

**Remark.** While this definition of the Fourier transform differs from the usual one, which involves the Euclidean inner product of \( \mathbb{R}^2 \)

\[
\langle (x, y), (x', y') \rangle = xx' + yy'
\]

rather than the symplectic form \( \omega \), it is equivalent to it in a natural way. Indeed, since \( \omega \) is nondegenerate there is a unique invertible skew symmetric linear operator \( \Omega \) on the two dimensional real vector space \( \mathbb{R}^2 \) satisfying \( \omega(z, z') = \langle \Omega z, z' \rangle \) for all \( z, z' \in \mathbb{R}^2 \). Hence one can pass back and forth from the usual Fourier transform of a measure to the one above by the invertible linear change-of-variables given by composing the transformed measure with either \( \Omega \) or \( \Omega^{-1} = -4\Omega \).

**Proposition 1.7.** Let \( \{W_z : z \in \mathbb{R}^2\} \) be an irreducible Weyl system acting on a Hilbert space \( H \). For every complex measure \( \mu \in M(\mathbb{R}^2) \) there is a unique normal completely bounded linear map \( \phi_\mu : \mathcal{B}(H) \to \mathcal{B}(H) \) satisfying

\[
\phi_\mu(W_z) = \hat{\mu}(z)W_z, \quad z \in \mathbb{R}^2.
\]

One has \( \phi_\mu \circ \phi_\nu = \phi_{\mu \ast \nu} \), and \( \|\phi_\mu\|_{cb} \leq \|\mu\| \), where \( \|\psi\|_{cb} \) denotes the completely bounded norm of an operator mapping \( \psi \). When \( \mu \) is a positive measure \( \phi_\mu \) is a completely positive map.

**proof.** Fix \( \mu \in M(\mathbb{R}^2) \). The uniqueness of the mapping \( \phi_\mu \) is apparent from the irreducibility hypothesis on the Weyl system, since the set of all linear combinations of the \( W_z, z \in \mathbb{R}^2 \), is a unital \( * \)-algebra which is weak*-dense in \( \mathcal{B}(H) \).
For existence, we exhibit $\phi_\mu(A)$ for $A \in \mathcal{B}(H)$ as a weak integral

\begin{equation}
(1.8) \quad \phi_\mu(A) = \int_{\mathbb{R}^2} W_{2-1/2\zeta}^* A W_{2-1/2\zeta} d\mu(\zeta),
\end{equation}

namely the operator defined by the bounded sesquilinear form on the right of (1.9)

\begin{equation}
(1.9) \quad \langle \phi_\mu(A) \xi, \eta \rangle = \int_{\mathbb{R}^2} \langle W_{2-1/2\zeta}^* A W_{2-1/2\zeta}, \xi \rangle \mu(\zeta), \quad \xi, \eta \in H.
\end{equation}

A straightforward estimate shows that $\|\phi_\mu(A)\| \leq \|A\| \cdot \|\mu\|$, and after promoting $\phi_\mu$ to $n \times n$ matrices over $\mathcal{B}(H)$ a similar estimate shows that $\|\phi_\mu\|_{cb} \leq \|\mu\|$. $\phi_\mu$ is obviously completely positive when $\mu$ is a positive measure.

Formula (1.9), together with a straightforward application of the bounded convergence theorem, implies that when $A_1, A_2, \ldots$ is a (necessarily bounded) sequence in $\mathcal{B}(H)$ which converges weakly to $A$, one has

$$\lim_{n \to \infty} \langle \phi_\mu(A) \xi, \eta \rangle = \langle \phi_\mu(A) \xi, \eta \rangle, \quad \xi, \eta \in H.$$ 

It follows that $\phi_\mu$ is a normal linear map.

Finally, from the commutation relation (1.3) we find that

$$W_{2-1/2\zeta} W_z W_{2-1/2\zeta}^* = W_{2-1/2\zeta} W_z W_{-2-1/2\zeta} = e^{-\omega(\zeta,z)} W_z,$$

and hence (1.8) implies that $\phi_\mu(W_z) = \hat{\mu}(z) W_z$.

\[\square\]

I want to thank Daniel Markiewicz for a suggestion that simplified the proof of Proposition 1.7.

**Theorem 1.10.** Let $W = \{W_z : z \in \mathbb{R}^2\}$ be an irreducible Weyl system. Then there is a unique CP semigroup $\phi = \{\phi_t : t \geq 0\}$ satisfying

\begin{equation}
(1.11) \quad \phi_t(W_z) = e^{-t|z|^2} W_z, \quad z \in \mathbb{R}^2.
\end{equation}

The only bounded normal linear functional $\rho$ for which $\rho \circ \phi_t = \rho$ for all $t \geq 0$ is $\rho = 0$. In particular, there is no normal state of $\mathcal{B}(H)$ which is invariant under $\phi$.

**proof.** For each $t \geq 0$, $u_t(z) = e^{-t|z|^2}$ is a continuous function of positive type, which takes the value 1 at $z = 0$. Thus it is the Fourier transform of a unique probability measure $\mu_t \in M(\mathbb{R}^2)$. We will require an explicit formula for the Gaussian measure $\mu_t$ later on; but for purposes of this section we require nothing more than its existence and uniqueness.

Since $u_s(z)u_t(z) = u_{s+t}(z)$ for all $z \in \mathbb{R}^2$ it follows that $\mu_s \ast \mu_t = \mu_{s+t}$. Hence Proposition 1.7 implies that there is a semigroup $\phi = \{\phi_t : t \geq 0\}$ of normal completely positive maps on $\mathcal{B}(H)$ which satisfies (1.11). It is a simple matter to check that the required continuity of $\phi_t$ in $t$ follows from the continuity of the right side of (1.11) in $t$ for fixed $z$.

Suppose now that $\rho$ is a normal linear functional which is invariant under $\phi$. Then for every $z \in \mathbb{R}^2$ and every $t \geq 0$, the definition of $\phi_t$ implies that

$$\rho(W_z) = \rho(\phi_t(W_z)) = e^{-t|z|^2} \rho(W_z)$$
and for fixed \( z \neq 0 \), the right side tends to 0 as \( t \to \infty \). Hence \( \rho(W_z) = 0 \) for every \( z \neq 0 \); by strong continuity on the unit ball it follows that \( \rho(1) = \omega(W_0) = 0 \). Hence \( \rho \) vanishes on the irreducible \(*\)-algebra spanned by \( W_z, z \in \mathbb{R}^2 \) and by normality it follows that \( \rho = 0 \).

\[ \text{Remarks.} \] We point out that while \( \phi \) has no normal invariant states, it does have a normal invariant weight...namely the trace, in that

\[ \text{trace} (\phi_t(A)) = \text{trace} (A) \]

for every positive operator \( A \in B(L^2(\mathbb{R})) \) and every \( t \geq 0 \). One sees this immediately from (1.8). It follows that \( \phi_t \) leaves the \( C^* \)-algebra \( K \) of all compact operators invariant, \( \phi_t(K) \subseteq K \). Since \( K \) is the \( C^* \)-algebra associated with the canonical commutation relations (more precisely, \( K \) is the enveloping \( C^* \)-algebra of all Weyl integral operators associated with the canonical commutation relations with a finite number of degrees of freedom), this justifies viewing the semigroup of restrictions \( \{ \phi_t |_K : t \geq 0 \} \) as the heat flow of the canonical commutation relations.

We also remark that one can deduce the existence of other CP semigroups along similar lines. For example, the proof of Theorem 1.10 implies that there is a “Cauchy” semigroup \( \psi = \{ \psi_t : t \geq 0 \} \) which is defined uniquely by the requirement

\[ \psi_t(W_z) = e^{-t(|x|+|y|)}W_z, \quad z = (x, y) \in \mathbb{R}^2, \]

and which has properties similar to those discussed above for \( \phi = \{ \phi_t : t \geq 0 \} \).

2. Harmonic analysis of the commutation relations.

A classical theorem of Beurling asserts that singletons obey spectral synthesis. More precisely, if \( G \) is a locally compact abelian group and \( f \) is an integrable function on \( G \) whose Fourier transform vanishes at a point \( p \) in the dual of \( G \), then there is a sequence of functions \( f_n \in L^1(G) \) such that \( \|f - f_n\| \to 0 \) as \( n \to \infty \) and such that the Fourier transform of each \( f_n \) vanishes identically on some open neighborhood \( U_n \) of \( p \). The purpose of this section is to present a noncommutative version of that result, which will be required in section 3.

Let \( \{W_z : z \in \mathbb{R}^2 \} \) be an irreducible Weyl system acting on a Hilbert space \( H \) (for example, one may take the Weyl system (1.2) acting on \( L^2(\mathbb{R}^2) \)). For every trace-class operator \( A \in L^1(H) \) we consider the following analogue of the Fourier transform \( \hat{A} : \mathbb{R}^2 \to \mathbb{C} \)

\[ \hat{A}(z) = \text{trace}(AW_z), \quad z \in \mathbb{R}^2. \]

This transform \( A \in L^1(H) \to \hat{A} \) shares many features in common with the commutative Fourier transform. For example, using the concrete realization (1.2), it is quite easy to establish a version of the Riemann-Lebesgue lemma

\[ \lim_{|z| \to \infty} \hat{A}(z) = 0, \]

for every \( A \in L^1(H) \). What we actually require is the following analogue of Beurling’s theorem, which lies somewhat deeper.
Theorem 2.1. Let $A \in \mathcal{L}^1(H)$ and let $\zeta \in \mathbb{R}^2$ be such that $\text{trace}(AW_\zeta) = 0$. There is a sequence $A_n \in \mathcal{L}^1(H)$ and a sequence of open neighborhoods $U_n$ of $\zeta$ such that
\[
\text{trace}(A_n W_\zeta) = 0, \quad \zeta \in U_n,
\]
and such that $\text{trace}|A - A_n| \to 0$ as $n \to \infty$.

proof. By replacing $A$ with $AW_\zeta$ and making obvious use of the canonical commutation relations (1.3), we may immediately reduce to the case $\zeta = 0$. We find it more convenient to establish the dual assertion of Theorem 2.1. For that, consider the following linear subspaces of $\mathcal{B}(H)$
\[
S_\epsilon = \text{span}\{W_z : |z| \leq \epsilon\}, \quad \epsilon > 0,
\]
the closure being taken relative to the weak* topology on $\mathcal{B}(H)$. Obviously the spaces $S_\epsilon$ decrease as $\epsilon$ decreases, and the identity operator belongs to $S_\epsilon$ for every $\epsilon > 0$. The pre-annihilator of $S_\epsilon$ is identified with the space of all trace-class operators $A$ satisfying
\[
(2.2) \quad \hat{A}(z) = \text{trace}(AW_z) = 0, \quad |z| \leq \epsilon.
\]

Lemma 2.3. Let $\{W_z : z \in \mathbb{R}^2\}$ be an arbitrary Weyl system acting on a separable Hilbert space $H$. Then $\cap\{S_\epsilon : \epsilon > 0\} = C \cdot 1$.

proof of Lemma 2.3. Let $S_0$ denote the intersection $\cap\{S_\epsilon : \epsilon > 0\}$. We have already remarked that the inclusion $\supseteq$ is obvious. For the opposite one, consider the von Neumann algebra $\mathcal{M}$ generated by $\{W_z : z \in \mathbb{R}^2\}$. $\mathcal{M}$ is a factor (of type $I_\infty$) because of the Stone-von Neumann theorem. We will show that $S_0$ is contained in the center of $\mathcal{M}$.

For that, choose $T \in S_0$ and consider the operator-valued function $z \mapsto W_z T W_z^*$. We have to show that this function is constant; equivalently, we will show that for fixed $\xi$ and $\eta$ in $H$, the function
\[
(2.4) \quad z \in \mathbb{R}^2 \mapsto \langle W_z T W_z^* \xi, \eta \rangle
\]
is constant. Since the function of (2.4) is bounded and continuous, it suffices to show that its spectrum (in the sense of spectral synthesis for functions in $L^\infty(\mathbb{R}^2)$) is the singleton $\{0\}$: this is the dual formulation of Beurling’s theorem cited above. Thus we have to show that for every function $f \in L^1(\mathbb{R}^2)$ whose Fourier transform
\[
\hat{f}(\zeta) = \int_{\mathbb{R}^2} e^{i\omega(z,\zeta)} f(z) \, dz
\]
vanishes throughout a neighborhood of the origin $\zeta = 0$, we have
\[
(2.5) \quad \int_{\mathbb{R}^2} f(z) \langle W_z T W_z^* \xi, \eta \rangle \, dz = 0.
\]

Fix such an $f \in L^1(\mathbb{R}^2)$ and choose $\epsilon > 0$ small enough so that $\hat{f}(\zeta) = 0$ for all $\zeta$ satisfying $|\zeta| \leq \epsilon$. Since the linear functional
\[
X \in \mathcal{B}(H) \mapsto \int_{\mathbb{R}^2} f(z) \langle W_z X W_z^* \xi, \eta \rangle \, dz
\]
is weak*-continuous and $T$ belongs to the weak*-closed linear span of operators of the form $W_\zeta$ with $|\zeta| \leq \epsilon$, to prove (2.5) it suffices to show that for every $\zeta$ with $|\zeta| \leq \epsilon$ we have

$$\int_{\mathbb{R}^2} f(z) \langle W_z W_\zeta W_z^* \xi, \eta \rangle \, dz = 0. \quad (2.6)$$

Using the canonical commutation relations we can write

$$W_z W_\zeta W_z^* = e^{i\omega(z,\zeta)} W_{z+\zeta} W_{z-\zeta} = e^{i\omega(\zeta,-z)} W_\zeta = e^{i\omega(z,\zeta)} W_\zeta.$$

Hence the left side of (2.6) becomes

$$\int_{\mathbb{R}^2} f(z) e^{i\omega(z,\zeta)} \langle W_\zeta \xi, \eta \rangle \, dz = \hat{f}(\zeta) \langle W_\zeta \xi, \eta \rangle,$$

and the latter term vanishes because $\hat{f}(\zeta) = 0$ for $|\zeta| \leq \epsilon$.

To complete the proof of Theorem 2.1, choose an operator $A \in L^1(H)$ satisfying

$$\hat{A}(0) = \text{trace}(A) = 0,$$

and consider the linear functional $\rho$ defined on $\mathcal{B}(H)$ by $\rho(T) = \text{trace}(AT)$. $\rho$ obviously vanishes on $\mathbb{C} \cdot 1$. The linear spaces $\mathcal{S}_\epsilon$ are weak*-closed and they decrease to $\mathcal{S}_0 = \mathbb{C} \cdot 1$ as $\epsilon$ decreases to 0, by Lemma 2.3. Since $\rho$ is weak*-continuous we must have

$$\lim_{\epsilon \to 0} \| \rho \restriction_{\mathcal{S}_\epsilon} \| = \| \rho \restriction_{\mathbb{C} \cdot 1} \| = 0.$$

Thus we can choose a sequence $\epsilon_n \downarrow 0$ so that $\| \rho \restriction_{\mathcal{S}_{\epsilon_n}} \| \leq 1/n$ for every $n = 1, 2, \ldots$. We have already pointed out that the pre-annihilator of $\mathcal{S}_{\epsilon_n}$ is identified with all trace class operators $B$ satisfying

$$\hat{B}(z) = \text{trace}(BW_z) = 0, \quad |z| \leq \epsilon_n. \quad (2.7)$$

Since $\| \rho \restriction_{\mathcal{S}_{\epsilon_n}} \|$ is the trace-norm distance from $A$ to the pre-annihilator of $\mathcal{S}_{\epsilon_n}$, we conclude that there is a sequence of operators $B_n \in L^1(H)$ which satisfy $\text{trace}(B_n W_z) = 0$ for $|z| \leq \epsilon_n$, such that $\text{trace}|A - B_n| \leq 2/n$, as asserted.

3. Purity and dilation theory.

An $E_0$-semigroup is a CP semigroup $\alpha = \{ \alpha_t : t \geq 0 \}$, acting on $\mathcal{B}(H)$, such that the individual maps are endomorphisms, $\alpha_t(AB) = \alpha_t(A)\alpha_t(B)$, $A, B \in \mathcal{B}(H)$. An $E_0$-semigroup $\alpha$ is called pure if its “tail” von Neumann algebra is trivial,

$$\bigcap_{t \geq 0} \alpha_t(\mathcal{B}(H)) = \mathbb{C} \cdot 1. \quad (3.1)$$

It is known that an $E_0$-semigroup is pure iff for any pair of normal states $\rho_1, \rho_2$ of $\mathcal{B}(H)$ we have

$$\lim_{t \to \infty} \| \rho_1 \circ \alpha_t - \rho_2 \circ \alpha_t \| = 0 \quad (3.2)$$
see [1].

If a pure $E_0$-semigroup $\alpha$ has a normal invariant state $\omega$, then the characterization (3.2) implies that $\omega$ must be an absorbing state in the sense that for every normal state $\rho$ of $\mathcal{B}(H)$ one has

$$\lim_{t \to \infty} \|\rho \circ \alpha_t - \omega\| = 0.$$  

Conversely, if for an arbitrary $E_0$-semigroup $\alpha$ there is a state $\omega$ of $\mathcal{B}(H)$ which is absorbing in the sense that (3.3) is satisfied for every normal state $\rho$ of $\mathcal{B}(H)$, then $\omega$ must be a normal invariant state, and thus by (3.2) $\alpha$ must be a pure $E_0$-semigroup.

In the theory of interactions worked out in [2], pure $E_0$-semigroups occupy a central position, especially those for which there is a normal invariant (and therefore absorbing) state. A natural question that emerges from the theory of interactions is whether or not every pure $E_0$-semigroup must have a normal invariant state. Now since the state space of $\mathcal{B}(H)$ is weak*-compact, a routine application of the Markov-Kakutani fixed point theorem shows that every $E_0$-semigroup must have invariant states; but invariant states obtained by such methods need not be normal. In this section we exhibit a concrete $E_0$-semigroup which is pure but which has no normal invariant states. This is a result which was asserted (without proof) in [2]. This $E_0$-semigroup is obtained from the CP semigroup of Theorem 1.10 by a dilation procedure.

In order that the minimal dilation of a CP semigroup to an $E_0$-semigroup should satisfy (3.1), it is necessary and sufficient that the CP semigroup should satisfy property (3.2) (see Proposition 3.5). Thus we generalize the definition of pure $E_0$-semigroup as follows.

**Definition 3.4.** A CP semigroup $\phi$ acting on $\mathcal{B}(H)$ is called pure if for every pair of normal states $\rho_1, \rho_2$ of $\mathcal{B}(H)$ we have

$$\lim_{t \to \infty} \|\rho_1 \circ \phi_t - \rho_2 \circ \phi_t\| = 0.$$  

**Proposition 3.5.** Let $\phi = \{\phi_t : t \geq 0\}$ be a pure CP semigroup which has no normal invariant state, and let $\alpha$ be its minimal dilation to an $E_0$-semigroup. Then $\alpha$ satisfies (3.1) and has no normal invariant state.

**proof.** The proof is straightforward, but we require results from [1]. Proposition 2.4 of [1] implies that $\alpha$ satisfies (3.1).

To see that $\alpha$ has no normal invariant state, we can assume that $\alpha$ acts on $\mathcal{B}(H)$ for some Hilbert space $H$ and that there is a closed subspace $K \subseteq H$ such that $\phi$ is the compression of $\alpha$ onto $\mathcal{B}(K) = PB(H)P$, $P$ denoting the projection of $H$ onto $K$. We have $\alpha_t(P) \uparrow 1$ because $\alpha$ is minimal over $P$. So if $\omega$ is any normal state of $\mathcal{B}(H)$ which is invariant under $\alpha$ then we have

$$\omega(P) = \lim_{t \to \infty} \omega(\alpha_t(P)) = \omega(1) = 1.$$  

Thus the restriction of $\omega$ to $\mathcal{B}(K) = PB(H)P$ defines a normal $\phi$-invariant state on $\mathcal{B}(K)$, contradicting the hypothesis on $\phi$. 

In the remainder of this section we show that the CP semigroup defined in Theorem 1.10 is pure. Once that is established, Proposition 3.5 implies that its minimal dilation is an $E_0$-semigroup with properties asserted in the discussion above.
Theorem 3.6. The CP semigroup $\phi$ defined in (1.11) is pure.

Before giving the proof, we require

Lemma 3.7. For each $t > 0$ let $\mu_t$ be the Gaussian measure on $\mathbb{R}^2$ whose Fourier transform (1.6) is given by

$$\hat{\mu}_t(z) = e^{-t|z|^2}, \quad z \in \mathbb{R}^2,$$

and choose $\delta > 0$. There is a family $\nu_t$, $t > 0$, of probability measures on $\mathbb{R}^2$ such that

(i) $\hat{\nu}_t(z) = 0$ for all $|z| \geq \delta$ and every $t$, and

(ii) $\lim_{t \to \infty} \| \mu_t - \nu_t \| = 0$, $\| \cdot \|$ denoting the norm of the measure algebra $M(\mathbb{R}^2)$.

proof. For $t > 0$, $\mu_t$ is given by $d\mu_t = u_t(x,y) \, dx \, dy$, where

$$u_t(x,y) = \frac{1}{\pi t} e^{-\frac{x^2 + y^2}{4t}}.$$

Let $f_t = \sqrt{u_t}$. $f_t$ belongs to $L^2(\mathbb{R}^2)$ and $\|f_t\|_2 = 1$. Choose a function $g \in L^1(\mathbb{R}^2)$ whose Fourier transform

$$\hat{g}(\zeta) = \int_{\mathbb{R}^2} e^{i\omega(\zeta,z)} g(z) \, dz$$

satisfies $0 \leq \hat{g}(\zeta) \leq 1$ for all $\zeta$, and

$$\hat{g}(\zeta) = \begin{cases} 1, & \text{for } 0 \leq |\zeta| \leq \delta/4 \\ 0, & \text{for } |\zeta| \geq \delta/2. \end{cases}$$

Consider the convolution $g * f_t \in L^2(\mathbb{R}^2)$ and the positive measure

$$d\nu_t = |g * f_t|^2 \, dx \, dy.$$

$\nu_t$ is obviously a positive finite measure. We claim first that the Fourier transform of $\nu_t$ lives in the disk $|\zeta| \leq \delta$. Indeed, letting $U_\zeta$ (resp. $T_\zeta$) be the unitary operator on $L^2(\mathbb{R}^2)$ (resp. $L^2(\hat{\mathbb{R}}^2)$) given by

$$U_\zeta F(z) = e^{i\omega(\zeta,z)} F(z), \quad T_\zeta G(w) = G(w + \zeta),$$

we have by the Plancherel theorem

$$\hat{\nu}_t(\zeta) = \langle U_\zeta(g * f_t), g * f_t \rangle_{L^2(\mathbb{R}^2)} = \langle T_\zeta(\hat{g} f_t), \hat{g} f_t \rangle_{L^2(\hat{\mathbb{R}}^2)}$$

$$= \int_{\mathbb{R}^2} (\hat{g} f_t)(w + \zeta) (\hat{g} f_t)(w) \, dw.$$

When $|\zeta| \geq \delta$ the integrand on the right vanishes identically in $w$ because $\hat{g} f_t$ is supported in the disk of radius $\delta/2$. Hence $\hat{\nu}_t(\zeta) = 0$ for $|\zeta| \geq \delta$.

To establish property (ii), it is enough to show that

$$\lim_{t \to \infty} \| f_t - g * f_t \|_2 = 0,$$

(3.8)
since by the Schwarz inequality
\[ \|\mu_t - \nu_t\| = \int_{\mathbb{R}^2} |f_t^2 - |g * f_t|^2| \, dz \leq \int_{\mathbb{R}^2} |f_t - g * f_t| \cdot |f_t + g * f_t| \, dz \]
\[ \leq \|f_t - g * f_t\|_2 \cdot \|f_t + g * f_t\|_2 \leq \|f_t - g * f_t\|_2 (\|f_t\|_2 + \|g * f_t\|_2). \]

To establish (3.8), we use the Plancherel theorem again to write
\[ \int_{\mathbb{R}^2} |f_t(z) - g * f_t(z)|^2 \, dz = \int_{\mathbb{R}^2} |\hat{f}(\zeta) - \hat{g}(\zeta)\hat{f}_t(\zeta)|^2 \, d\zeta = \int_{\mathbb{R}^2} |1 - \hat{g}(\zeta)|^2 \cdot |\hat{f}_t|^2 \, d\zeta. \]
The function \(|1 - \hat{g}(\zeta)|\) is bounded above by 1 and it vanishes throughout the disk \(0 \leq |\zeta| \leq \delta/4\). Hence the term on the right is dominated by
\[ (3.9) \int \{ |\zeta| \geq \delta/4 \} |\hat{f}_t(\zeta)|^2 \, d\zeta. \]
In order to estimate the integral (3.9) we require the explicit formula
\[ f_t(x, y) = \sqrt{u_t(x, y)} = \frac{1}{\sqrt{\pi t}} e^{-\frac{x^2+y^2}{8t}}. \]
The Fourier transform of \(f_t\) has the form
\[ \hat{f}_t(\zeta) = K \sqrt{t} e^{-2t|\zeta|^2} \]
where \(K\) is a positive constant, hence (3.9) evaluates to
\[ K^2 t \int \{ |\zeta| \geq \delta/4 \} e^{-4t|\zeta|^2} \, d\zeta = K^2 \int_{S_t} e^{-4(u^2+v^2)} \, du \, dv, \]
where \(S_t = \{ (u, v) : \sqrt{u^2+v^2} \geq (\delta/4)\sqrt{t} \}\). As \(t \to \infty\) the sets \(S_t\) decrease to 0, hence the right side of the previous expression tends to 0, and (3.8) is proved.

The positive measures \(\nu_t\) are not necessarily probability measures, but in view of the established property (ii), \(\nu_t(\mathbb{R}^2)\) must be arbitrarily close to \(\mu_t(\mathbb{R}^2) = 1\) when \(t\) is large. Hence we can rescale \(\nu_t\) in an obvious way to achieve \(\nu_t(\mathbb{R}^2) = 1\) for all \(t > 0\) as well as the properties (i) and (ii) of Lemma 3.7.

\[ \text{proof of Theorem 3.6.} \]

Let \(W_z, z \in \mathbb{R}^2\) be an irreducible Weyl system acting on a Hilbert space \(H\), and let \(\phi = \{ \phi_t : t \geq 0 \}\) be the CP semigroup defined by the condition
\[ \phi_t(W_z) = e^{-|t|z^2} W_z, \quad z \in \mathbb{R}^2. \]
Choose a pair of normal states \(\rho_1, \rho_2\) on \(B(H)\), and consider their difference \(\omega = \rho_1 - \rho_2\). We have to show that
\[ (3.10) \lim_{t \to \infty} \|\omega \circ \phi_t\| = 0. \]
For that, let \(A\) be the self-adjoint trace-class operator defined by \(\text{trace}(AT) = \omega(T)\), \(T \in B(H)\) and choose \(\epsilon > 0\). \(A\) has trace zero, so by Theorem 2.1, we can find a
self-adjoint trace-class operator $A_0$ such that trace$(A_0W_z) = 0$ for every $z$ in some neighborhood $U$ of $z = 0$, and $\text{trace} |A - A_0| \leq \epsilon$. It follows that the normal linear functional $\omega_0(T) = \text{trace}(A_0T)$ satisfies $\|\omega - \omega_0\| \leq \epsilon$ and $\omega_0(W_z) = 0$ for $z \in U$.

By Lemma 3.5 we can find probability measures $\nu_t$, $t > 0$, such that $\hat{\nu_t}(z)$ vanishes for $z \notin U$ and $\|\mu_t - \nu_t\|$ tends to 0 as $t \to \infty$. For each $t > 0$ let $\psi_t$ be the completely positive map defined by Proposition 1.7,

$$\psi_t(W_z) = \hat{\nu_t}(z)W_z, \quad z \in \mathbb{R}^2.$$ 

In order to prove (3.10) we decompose the linear functional $\omega \circ \phi_t$ into a sum of three terms as follows

(3.11) \[ \omega \circ \phi_t = (\omega - \omega_0) \circ \phi_t + \omega_0 \circ (\phi_t - \psi_t) + \omega_0 \circ \psi_t. \]

The third term on the right of (3.11) is zero because for every $z \in \mathbb{R}^2$ we have

$$\omega_0(\psi_t(W_z)) = \omega_0(\hat{\nu_t}(z)W_z) = \hat{\nu_t}(z)\omega_0(W_z) = 0,$$

since $\hat{\nu_t}(z)$ vanishes when $z \notin U$ and $\omega_0(W_z)$ vanishes when $z \in U$ (recall that the linear span of the $W_z$ for $z \in \mathbb{R}^2$ is a strongly dense *-subalgebra of $\mathcal{B}(H)$). The first term on the right of (3.11) is estimated for arbitrary $t$ by

$$\| (\omega - \omega_0) \circ \phi_t \| \leq \| \omega - \omega_0 \| \leq \epsilon.$$

In order to estimate the second term, note that

(3.12) \[ \| \phi_t - \psi_t \| \leq \| \mu_t - \nu_t \| \]

for every $t > 0$. Indeed, considering the measure $\sigma_t = \mu_t - \nu_t \in M(\mathbb{R}^2)$, we can write

$$\phi_t(W_z) - \psi_t(W_z) = \hat{\mu_t}(z)W_z - \hat{\nu_t}(z)W_z = \hat{\sigma_t}(z)W_z.$$ 

It follows from Proposition 1.7 that the completely bounded norm of the operator mapping $\phi_t - \psi_t$ is at most $\| \sigma_t \| = \| \mu_t - \nu_t \|$, hence (3.12).

From (3.11) and these estimates we may conclude that

$$\limsup_{t \to \infty} \| \omega \circ \phi_t \| \leq \epsilon + \lim_{t \to \infty} \| \mu_t - \nu_t \| + 0 = \epsilon.$$

Since $\epsilon$ is arbitrary the limit (3.10) is proved.

\[ \square \]
