Influence of Frequency and Dates of Plant Growth Regulator Applications to Centipedegrass on Seedhead Formation and Turf Quality

Billy J. Johnson

Department of Agronomy, University of Georgia, Georgia Station, Griffin, GA 30223-1797

Abstract. Two separate experiments (one and two applications and dates of treatment) were conducted on plant growth regulator (PGR) injury and seedhead suppression of centipedegrass [Eremochloa ophiuroides (Munro) Hack.]. Mefluidide caused less injury to centipedegrass than either imazethapyr or flurprimidol + mefluidide. Mefluidide applied at 0.56 kg·ha⁻¹ in each of two applications at 2-week intervals suppressed seedheads of centipedegrass for 10 weeks. A single 0.56-kg·ha⁻¹ application of the mefluidide failed to suppress seedheads when applied any time from mid-June until late July. A single treatment with flurprimidol + mefluidide severely injured centipedegrass, and seedhead suppression was poor regardless of date of treatment. Centipedegrass was severely injured when flurprimidol + mefluidide was applied at 1.68 + 0.28 kg·ha⁻¹ in each of two applications, but seedheads were suppressed for 10 weeks. Imazethapyr applied at 0.30 and followed by 0.15 kg·ha⁻¹ suppressed seedheads 10 weeks after treatment in 1987 and 6 weeks after treatment in 1988 without reducing turf density. When this PGR was applied as a single treatment at 0.30 kg·ha⁻¹, seedhead suppression was generally greater for 8 weeks when applied mid- to late July than mid- to late June. Chemical names used: N-[2,4-dimethyl-5-[[[trifluoromethyl)sulfonyl]amino]phenyl]-5-pyrimidinemethanol (flurprimidol); and (±)-2-[4,5-dihydro-4-methyl-4-[1-methylethyl]-5-oxo-1H-imidazol-2-yl]-5-ethyl-3-pyridinecarboxylic acid (imazethapyr).

Plant growth regulators are applied to turfgrasses to retard vegetative growth and/or to suppress seedheads. Centipedegrass is a low-maintenance grass (Johnson et al., 1988a, 1988b) and requires only infrequent mowing throughout the growing season; therefore, PGRs are generally not needed for the suppression of vegetative growth of this species. However, centipedegrass seedheads are numerous during mid-summer, and frequent mowing is required to maintain a turf free of seedheads. If PGRs could be applied to centipedegrass to inhibit seedhead formation, mowing frequency could be reduced during this period.

Plant growth regulators have been evaluated for seedhead suppression of cool-season grasses (Bhowmik, 1987; Christians, 1985; Demoedon, 1984; Johnson, 1989b; McCarty et al., 1985). However, limited information is available on centipedegrass, for which a single treatment with either imazethapyr, mefluidide, or flurprimidol + mefluidide did not effectively suppress seedhead development for 8 weeks (Johnson, 1989a). In that experiment, imazethapyr suppressed >70% of centipedegrass seedheads for 6 weeks, but severely injured the grass in 1 of 2 years. Neither mefluidide applied alone nor with flurprimidol effectively suppressed seedheads during this period.

Kaufmann (1985) reported that the preferred time to apply a PGR to cool-season grasses is just before the peak growth period. Seedhead suppression of tall fescue (Festuca arundinacea Schreb. ‘Ky 31’) in North Carolina (DiPaola et al., 1985) was unacceptable when PGRs were applied later than 2 weeks before the emergence of the inflorescences. Plant growth regulators applied in late May to common bermudagrass [Cynodon dactylon (L.) Pers.] in Arkansas (Rogers et al., 1987) suppressed vegetative growth more than when applied in July. Similar results were also observed on ‘Tifway’ bermudagrass (C. transvaalensis Burtt-Davy) × [C. dactylon (L.) Pers.] in Georgia (Johnson, 1988).

To obtain a more consistent response of PGRs on centipedegrass, experiments were conducted to determine the effects of one and two PGR applications and dates of PGR treatments on injury and seedhead suppression of centipedegrass.

Materials and Methods

Two PGR experiments were conducted on a mature stand of centipedegrass maintained at a 4.5-cm cutting height during 1987 and 1988. In both experiments, the turf was cut with a rotary mower and clippings were returned up to 1 week before treatment. On the day of treatment, the grass was cut and clippings were removed. At 2-week intervals after PGR treatments, one-half of each plot was mowed and one-half was not mowed throughout the study. Centipedegrass is normally mowed at 2-week intervals in Georgia.

One and two PGR applications (Expt. 1). Centipedegrass was treated with mefluidide, flurprimidol + mefluidide, and imazethapyr at various amounts in one or two applications (Table 1). An untreated control was included. Dates of treatments were 30 June and 15 July 1987 and 7 and 19 July 1988. Plant growth regulator treatments were arranged in a randomized complete-block design with four replications. Since one-half of the plots was mowed and one-half was not mowed, a split-block arrangement was created; treatments in the mowed and unmowed plots were analyzed separately.

Date of PGR application (Expt. 2). Centipedegrass was treated with a single application of mefluidide at 0.56 kg·ha⁻¹, flurprimidol + mefluidide at 1.68 + 0.28 kg·ha⁻¹, and imazethapyr at 0.30 kg·ha⁻¹ on 16 June, 30 June, 15 and 27 July 1987; and on 16 June, 28 June, 13 July, and 26 July 1988. An untreated control was included at each date of treatment. The experimental design was a split plot with four replications in 1987 and three replications in 1988. Dates of PGR treatments were randomized within blocks for the whole plots and PGR treatments were randomized within subplots.
Table 1. Influence of one and two plant growth regulator applications on injury of centipedegrass in Expt. 1 at Griffin, Ga.

| Plant growth regulator | Turf injury after indicated interval (weeks)

*Treatments were applied 30 June and 15 July 1987 and 7 and 19 July 1988. When PGRs were applied only once, it was at the earliest date.
†Turfgrass injury was rated at times indicated after the first PGR treatment and based on 0 = no injury, ≥ 30 = unacceptable, and 100 = complete kill. Data are the means of four observations.

Results and Discussion

One and two PGR applications (Expt. 1)

Turf injury. Mefluidide applied as a single treatment at 0.56 kg·ha⁻¹ injured centipedegrass only slightly (Table 1). In most instances, the injury was similar whether 0.56 kg·ha⁻¹ was applied as a single application or 0.28 kg·ha⁻¹ was applied in each of two applications. Mefluidide applied at 0.56 kg·ha⁻¹ in each of two applications caused 16% centipedegrass injury in 1987 and 23% in 1988 at 4 weeks after the initial application. The injury in 1988 significantly reduced density of turf according to ratings made 10 weeks after the first mefluidide treatment (Table 2).

Flurprimidol + mefluidide at 1.68 + 0.28 kg·ha⁻¹ as a single application injured centipedegrass too severely in 1 of 2 years to be acceptable (Table 1). The highest injury (45%) was at 4 weeks after treatment in 1988. This was higher than obtained in 1987 (22%) or in an earlier study (29%) (Johnson, 1989a). There was no difference in 1988 whether flurprimidol + mefluidide was applied as a single treatment at 1.68 + 0.28 kg·ha⁻¹ or at the one-half rate in each of two applications at 4 weeks or later. When the full rate was applied twice, maximum

General information. A nonionic surfactant (alkylarylpoloxylene glycols free fatty acid isopropanol) was applied with mefluidide and flurprimidol + mefluidide at 0.5% (v/v) and with imazethapyr at 0.25% (v/v). Treatments were applied to different plots each year. Plot size was 1.5 × 3 m. The PGRs were applied as a broadcast spray in 375 liter of water/ha.

Turf injury, density, and seedhead suppression of centipedegrass were rated visually. The injury ratings were made in the mowed areas from 1 to 10 weeks after PGR treatment and based on 0 = no injury, ≥ 30 = unacceptable, and 100 = complete kill. Data are the means of four observations. 

Table 2. Influence of one and two plant growth regulator applications on density of centipedegrass in Expt. 1 at Griffin, Ga.

| Plant growth regulator | Turf density (% of untreated) |

|                       | 0.30 + 0.15    | 109  | 99  |
| LSD 0.05              | 10             | 6    |

*Treatments were applied 30 June and 15 July 1987 and 7 and 19 July 1988. When PGRs were applied only once, it was at the earliest date.
†Turf density ratings were made 10 weeks after first PGR treatment and based on percent of nontreated check. Data are the means of four observations.
*Indicates that the density of treated centipedegrass was significantly lower than nontreated.

J. Amer. Soc. Hort. Sci. 115(3):412-416. 1990.
injury was 49% in 1987 and 61% in 1988, 4 weeks after the first treatment. By 10 weeks, turf treated with flurprimidol + mefluidide had recovered fully in 1987, while the turf treated with the same PGR combination in 1988 did not. Turf injury from this PGR combination was also reflected in lower density in 1988 (Table 2). Flurprimidol + mefluidide applied at any other level to centipedegrass in 1988, or at any level in 1987 did not reduce turf density 10 weeks after treatment.

Imazethapyr applied at 0.3 kg·ha⁻¹ as a single application or 0.15 kg·ha⁻¹ in each of two applications injured the turf only slightly after treatment either year (Table 1). However, the injury from the single 0.3-kg·ha⁻¹ treatment in the present study was less than that obtained in an earlier study (Johnson, 1989a). The safety of imazethapyr on centipedegrass may be questionable, since the grass was severely injured (44%) for a short period in 1 of 2 years when treated initially with 0.3 kg·ha⁻¹ and followed by 0.15 kg·ha⁻¹ 12 days later. However, the injury was temporary, as the turf recovered rapidly and the treatment did not affect density (Table 2).

Seedhead suppression. Mefluidide applied at 0.56 kg·ha⁻¹ as a single treatment did not effectively suppress centipedegrass seedheads (Table 3). However, the suppression was = 70% for 8 weeks when mefluidide was applied at 0.56 and followed with 0.28 kg·ha⁻¹. When 0.56 kg·ha⁻¹ was applied in two applications, the suppression was between 70% and 80% for 10 weeks.

Flurprimidol + mefluidide did not suppress seedheads of centipedegrass equally each year. Seedheads were effectively suppressed with a single application of flurprimidol + mefluidide at 1.68 + 0.28 kg·ha⁻¹ for 8 weeks in 1987, but only for 4 weeks in 1988 (Table 3). There was no significant benefit in length of suppression from flurprimidol + mefluidide when treated twice at the full + one-half amounts compared with a single full amount. However, the suppression at 10 weeks was 95% in 1987 and 72% in 1988 when the grass was treated twice at the full amount.

Imazethapyr suppressed seedheads of centipedegrass more in 1987 than 1988 (Table 3). A single 0.30-kg·ha⁻¹ treatment suppressed seedheads for 6 weeks in 1987, but only for 4 weeks in 1988. In an earlier study (Johnson, 1989a), suppression persisted for 6 weeks. Although not significant, the suppression with imazethapyr was improved in the present study in 1987 when applied at 0.15 kg·ha⁻¹ in each of two applications compared with a single 0.30-kg·ha⁻¹ treatment. When the PGR was applied at 0.30 kg·ha⁻¹ and followed with 0.15 kg·ha⁻¹, the suppression was improved to 94% at 10 weeks in 1987 and 83% at 6 weeks in 1988. The suppression in 1988 was reduced to 66% by 8 weeks.

Vegetative height. Centipedegrass maintained under low fertility level grew slowly, and the grass generally did not respond to PGRs except when not mowed. The grass not mowed was suppressed for 8 weeks when treated with a single application of mefluidide at 0.56 kg·ha⁻¹ (Table 4). Growth suppression was increased to 10 weeks when 0.28 kg·ha⁻¹ was applied in each of two applications.

Flurprimidol + mefluidide suppressed the vegetative growth of nonmowed centipedegrass for 10 weeks (Table 4). The growth at 10 weeks was suppressed 28% in plots treated once with flurprimidol + mefluidide at 1.68 + 0.28 kg·ha⁻¹ but suppressed nearly twice as much with treated with 1.68 + 0.28 kg·ha⁻¹ in each of two applications.

Imazethapyr suppressed vegetative growth of nonmowed centipedegrass, but amount and sequence of applications influenced the length of suppression (Table 4). When the PGR was applied at 0.3 kg·ha⁻¹ as a single application, centipedegrass growth

*The first PGR treatment was applied 7 July and the second on 19 July. When PGRs were applied only once, it was at the earliest date. Plant heights are averages from two years and ratings were made weeks after the first treatment and based on percent of nontreated check. The height of nontreated grass was 9.7 cm at 6 weeks, 14.3 cm at 8 weeks, and 15.5 cm at 10 weeks. Data are the means of four observations.

*Indicates that the height of treated centipedegrass was significantly lower than nontreated.
was suppressed for 6 weeks, but was suppressed for 8 weeks when applied at 0.15 kg·ha⁻¹ in each of two applications. The suppression was increased to 10 weeks when treated with imazethapyr at 0.3 kg·ha⁻¹ and followed by 0.15 kg·ha⁻¹.

The commercial use of PGRs on centipedegrass depends on injury to the grass and length of seedhead suppression. From the PGRs evaluated in this study, mefluidide applied at 0.56 kg·ha⁻¹ in each of two applications provided suppression with minimum turf injury during a 10-week period. A combination of flurprimidol + mefluidide severely injured centipedegrass in 1 of 2 years when applied as a single application, and seedhead suppression was not as good as with two mefluidide treatments at 0.56 kg·ha⁻¹. Imazethapyr applied in two applications (0.30 kg·ha⁻¹ in the first and 0.15 kg·ha⁻¹ in the second) suppressed seedheads of centipedegrass from 6 to 10 weeks, but severely injured the turf in 1 of 2 years.

Date of PGR treatments (Expt. 2)

The amount of injury and seedhead suppression of centipedegrass in the multiple-treatment experiment was influenced by the PGRs, but all treatments caused some degree of plant injury. Therefore, when PGRs are used, it is desirable to select dates of treatment where the least injury and highest seedhead suppression occur.

Turf injury. Mefluidide did not severely injure (≤30%) centipedegrass at any of the treatment dates (Table 5). However, less injury was noted when the PGR was applied 29 June (12% to 17%) or 14 July (15% to 18%) than when applied 16 June (23% to 25%) or 27 July (18% to 28%) when rated 3 weeks after treatment. However, with the variation, there was no clear date for the best mefluidide treatment. In most instances, mefluidide induced some degree of injury throughout the 10 weeks, but did not reduce turf density (data not shown).

The injury to centipedegrass was severe when treated with flurprimidol + mefluidide at any date when ratings were made 3 weeks after treatment (Table 5). Centipedegrass recovered more slowly when treated 29 June with the PGRs than at other dates when rated at 10 weeks.

Injury to centipedegrass treated with imazethapyr varied with dates of treatment (Table 5). Only with imazethapyr applied 29 June 1987 or 27 July 1988 was the injury >30% throughout the 10-week period. Although the difference in turf injury due to treatment dates may not always be significant, the injury from mefluidide was less when treated from 16 June until 14 July than when treated 27 July, and with imazethapyr when treated 16 June than at later dates. The injury of turf treated with flurprimidol + mefluidide was too severe to be applied to centipedegrass.

Seedhead suppression. When single PGR treatments were applied, the suppression of centipedegrass seedheads was more consistent with imazethapyr than with mefluidide or flurprimidol + mefluidide (Table 6). Imazethapyr suppressed seedheads of centipedegrass effectively for 4 weeks regardless of treatment date. However, by 6 weeks, the suppression was considered commercially acceptable only when the PGR was applied 14 or 27 July. At these dates, the effectiveness of imazethapyr did not last longer than 6 weeks in 1987, but persisted for 8 weeks in 1988. Seedhead suppression with mefluidide or flurprimidol + mefluidide was erratic in both years. By 8 weeks, the suppression of seedheads was effective with mefluidide when

Table 5. Influence of date of plant growth regulator application on injury of centipedegrass at Griffin, Ga.

Evaluation of Preemergent Herbicide Phytotoxicity to Tissue, Culture-propagated ‘Heritage’ Red Raspberry

Additional index words. napropamide, oryzalin, simazine, activated carbon, herbicide safening, planting-to-treatment interval, Rubus idaeus

Abstract. Five greenhouse and two field experiments were conducted to evaluate tissue culture-propagated (TC) raspberry (Rubus idaeus cv. Heritage) sensitivity to preemergent herbicides. Plant performance was measured by plant vigor, above-ground fresh weight, root development, and primocane number. Simazine and oryzalin caused significant injury to newly planted TC raspberry plants in greenhouse and field experiments. The severity of injury was generally linear with respect to herbicide rate, but no appreciable differences in injury were observed between the granular and spray applications. Napropamide wettable powder caused some foliar injury, but plants recovered within one growing season and growth was equal or superior to the hand-weeded controls. The granular formulation of napropamide produced similar results, but did not cause the initial foliar burn. Pre-plant dipping of roots into a slurry of activated carbon did not prevent simazine or oryzalin injury, but injury was reduced when herbicide applications were delayed. Simazine applied 4 weeks after planting was not injurious, and oqzalin applied 2 or 4 weeks after planting caused some foliar injury, but no reduction in plant fresh weight. Delayed treatments of napropamide increased foliar injury. Herbicide tolerance of tissue-cultured plantlets appeared to be less than that of conventionally propagated plants. Chemical names used: N,N-diethyl-2-(1-naphthalenyl)propanamide (napropamide), 4-(dipropylamino)-3,5-dinitrobenzenesulfonamide (simazine).

Weed control is an essential component in the management of newly planted and established raspberries. Inadequate weed control may result in reduced survival of new plantings (Lawson and Wiseman, 1976), decreased florican and primocane numbers (Lawson and Wiseman, 1974, 1976; Stephens and Sutherland, 1962), and thinner, less-vigorous canes (Welker and Smith, 1972). Weed competition not only affects plant growth during the growing season, but may also reduce new cane numbers the following year (Lawson and Wiseman, 1976). The effects of weeds on growth and yield have also been shown to be cumulative over time (Welker and Smith, 1972). Cultivation is used to control weedy vegetation between the rows of plants, but cannot be used within the plant rows: Hand-weeding is effective, but expensive; therefore, soil residual herbicides are generally used within the plant rows to prevent weed invasion.
