Abstract. In this paper, we extend Waldhausen’s results on algebraic K-theory of
generalized free products in a more general setting and we give some properties of the
Nil functors. As a consequence, we get new groups with trivial Whitehead groups.

Keywords: Algebraic K-theory, functor Nil, Whitehead groups.
Mathematics Subject Classification (2020): 18E10, 19D35, 19D50.

Introduction.

Quillen’s construction associates to any essentially small exact category $\mathcal{A}$ its
algebraic K-theory which is an infinite loop space $K(\mathcal{A})$ and this correspondence is
a functor from the category of essentially small exact categories to the category $\Omega sp_0$
of infinite loop spaces.

If $\mathcal{A}$ is the category $\mathcal{P}_A$ of finitely generated projective right modules over some
ring $A$, one gets a functor $A \mapsto K(A) = K(\mathcal{P}_A)$ and this functor can be enriched into
a new functor $K$ containing also the negative part of the algebraic K-theory. That is
$K$ is a functor from the category of rings to the category $\Omega sp$ of $\Omega$-spectra and the
natural transformation $K(A) \rightarrow K(A)$ induces a homotopy equivalence from $K(A)$
to the 0-th term of $K(A)$.

By a left-flat bimodule we mean a pair $(A,S)$ where $A$ is a ring and $S$ is an $A$-
bimodule flat on the left. The left-flat bimodules form a category where a morphism
$(A,S) \rightarrow (B,T)$ is a ring homomorphism $f : A \rightarrow B$ together with a morphism of
$A$-bimodules $\varphi : S \rightarrow f^*(T)$.

For each left-flat bimodule $(A,S)$ one has an exact category $\mathcal{Nil}(A,S)$ where the
objects are the pairs $(M,f)$ where $M$ is an object in $\mathcal{P}_A$ and $f : M \rightarrow M \otimes_A S$ is a
nilpotent morphism of right $A$-modules.

The correspondence $M \mapsto (M,0)$ induces a morphism $K(A) \rightarrow K(\mathcal{Nil}(A,S))$ and
this morphism has a retraction coming from the functor $(M,f) \mapsto M$. Thus there is
a functor $Nil$ from the category of left-flat bimodules to $\Omega sp_0$ which is unique up to

homotopy such that:

\[ K(\mathcal{Nil}(A, S)) \cong K(A) \times \mathcal{Nil}(A, S) \]

**Theorem 1.** There is a functor \( \mathcal{Nil} \) from the category of left-flat bimodules to the category \( \Omega sp \) of \( \Omega \)-spectra and a natural transformation \( \mathcal{Nil} \to \mathcal{Nil} \) such that the following holds for every left-flat bimodule \( (A, S) \):

- the map \( \mathcal{Nil}(A, S) \to \mathcal{Nil}(A, S) \) induces a homotopy equivalence from \( \mathcal{Nil}(A, S) \) to the 0-th term of \( \mathcal{Nil}(A, S) \)
- if \( R \) is the tensor algebra of \( S \), then there is a natural homotopy equivalence in \( \Omega sp \):

\[ K(R) \sim \to K(A) \times \Omega^{-1}(\mathcal{Nil}(A, S)) \]

Moreover if \( A \) is regular coherent on the right, every spectrum \( \mathcal{Nil}(A, S) \) is contractible.

Following a terminology of Waldhausen, a ring homomorphism \( \alpha : A \to B \) will be called pure if it is split injective as an \( A \)-bimodule homomorphism.

**Theorem 2.** Let \( \alpha : C \to A \) and \( \beta : C \to B \) be pure ring homomorphisms. Let \( R \) be the ring defined by the push-out diagram:

\[
\begin{array}{ccc}
C & \longrightarrow & A \\
\downarrow_{\beta} & & \downarrow \\
B & \longrightarrow & R
\end{array}
\]

and \( K'(R) \) be the \( \Omega \)-spectrum defined by the homotopy fibration in \( \Omega sp \):

\[ K(C) \xrightarrow{f} K(A) \times K(B) \to K'(R) \]

where \( f \) is the map \( K(\alpha) \times -K(\beta) \).

Suppose \( A \) and \( B \) are \( C \)-flat on the left. Then there exist a left-flat bimodule \( (C \times C, S) \) and a homotopy equivalence in \( \Omega sp \):

\[ K(R) \sim \to K'(R) \times \Omega^{-1}(\mathcal{Nil}(C \times C, S)) \]

**Theorem 3.** Let \( C \) and \( A \) be two rings and \( \alpha \) and \( \beta \) be two pure ring homomorphisms from \( C \) to \( A \). Let \( R \) be the ring generated by \( A \) and an invertible element \( t \) with the only relations:

\[ \forall c \in C, \quad \alpha(c)t = t\beta(c) \]
and $K'(R)$ be the $\Omega$-spectrum defined by the homotopy fibration:

$$K(C) \xrightarrow{f} K(A) \rightarrow K'(R)$$

where $f$ is the map $K(\alpha) - K(\beta)$.

Suppose $A$ is $C$-flat on the left via both $\alpha$ and $\beta$. Then there exist a left-flat bimodule $(C \times C, S)$ and a homotopy equivalence in $\Omega sp$:

$$K(R) \xrightarrow{\simeq} K'(R) \times \Omega^{-1} (\text{Nil}(C \times C, S))$$

The connective part of these theorems are generalization of the Waldhausen’s results in [Wa1], in the sense that the condition free on the left in [Wa1] may be replaced by the condition flat on the left and (in the polynomial extension case) the condition on the right may be removed.

Because of these results, the functor $\text{Nil}$ detects in some sense the default of excision in algebraic $K$-theory. So it would be useful to know when the spectrum $\text{Nil}(A, S)$ is contractible, especially if $A$ is not regular coherent. Actually we have the following result:

**Theorem 4.** Let $A$ and $B$ be two rings, $S$ be an $(A, B)$-bimodule and $T$ be a $(B, A)$-bimodule. Suppose $S$ and $T$ are flat on both sides. Using projections $A \times B \rightarrow A$ and $A \times B \rightarrow B$, $S$ and $T$ may be considered as $A \times B$-bimodules. Then we have natural homotopy equivalences of spectra:

$$\text{Nil}(A \times B, S \oplus T) \xrightarrow{\sim} \text{Nil}(A, S \otimes_B T)$$

$$\text{Nil}(A \times B, S \oplus T) \xrightarrow{\sim} \text{Nil}(B, T \otimes_A S)$$

We have other results concerning the spectrum $\text{Nil}(A, S)$ when the bimodule $S$ is a direct sum of bimodules: $S = \bigoplus_{i \in I} S_i$.

Let $W(I)$ be the set of words in the set $I$. This set is the unitary monoid freely generated by $I$. Let $CW(I)$ the set of cyclic words in $I$. The set $CW(I)$ is the quotient of $W(I)$ by the equivalence relation $uv \sim vu$ in $W(I)$. A word $u \in W(I)$ is said to be reduced if we have the following:

$$\forall v \in W(I), \ \forall p > 1, \ u \neq v^p$$

The set of reduced words is denoted by $W_0(I)$ and its image in $CW(I)$ is denoted by $CW_0(I)$. A subset $X \subset W(I)$ is said to be admissible if the projection $W(I) \rightarrow CW(I)$ induces a bijection $X \xrightarrow{\sim} CW_0(I)$. 

3
For every $u \in W(I)$, we have a bimodule $S_u$ defined by:

$$
u = 1 \implies S_u = A$$

$$
u = vi, \text{ with } i \in I, \implies S_u = S_v \otimes_A S_i$$

Using these notations, we have this result:

**Theorem 5:** Let $A$ be a ring and $S_i, i \in I$, be a family of $A$-bimodules. Suppose each bimodule $S_i$ is flat on both sides. Let $X$ be an admissible set in $W(I)$. Then we have a homotopy equivalence of spectra:

$$\text{Nil}(A, \oplus_i S_i) \sim \oplus_{u \in X} \text{Nil}(A, S_u)$$

where $\oplus$ is the coproduct in the category of spectra.

Moreover, using theorems 4 and 5, we can deduce this last result:

**Theorem 6:** Let $A$ be a ring, $S$ be an $A$-bimodule and $I$ be a set. For each $i \in I$, let $A_i$ be a right regular coherent ring, $E_i$ be an $(A, A_i)$-bimodule and $F_i$ be an $(A_i, A)$-bimodule. Suppose all these bimodules are flat on both sides. Then the inclusion:

$$S \subset S \oplus \oplus_i E_i \otimes_{A_i} F_i$$

induces a homotopy equivalence:

$$\text{Nil}(A, S) \sim \text{Nil}(A, S \oplus \oplus_i E_i \otimes_{A_i} F_i)$$

The paper is organized as follows:

In section 1, we construct many categories and functors in such a way they are defined in each of the three cases: the general polynomial extension case, the generalized free product case and the generalized Laurent extension case. We prove also many algebraic properties of these categories and functors.

In section 2, we apply these properties to algebraic K-theory and prove theorems 1, 2 and 3.

The section 3 is devoted to the proof of theorems 4, 5 and 6 about Nil functors.

In the last section we apply all these theorems and get new results about Whitehead spectra. In particular we construct a class $\mathcal{C}_1$ bigger than Waldhausen’s class $\mathcal{C}_1$ such that every group in $\mathcal{C}_1$ has trivial Whitehead groups.

1. **The categories $\mathcal{V}$ and $\mathcal{MV}$ and their algebraic properties.**

   In order to simplify the notations, the following writing conventions will often be used:
• Convention 1: if $\Phi : \mathcal{A} \to \mathcal{B}$ is a functor, then for every morphism $\alpha$ in $\mathcal{A}$, its image under $\Phi$ will be still denoted by $\alpha$. So, if $\alpha : X \to Y$ is a morphism, we have a morphism $\alpha : \Phi(X) \to \Phi(Y)$.

• Convention 2: if $E$ is a right module over some ring $A$ and $F$ is a left module over the same ring, then the module $E \otimes_A F$ will be simply denoted be $EF$. In the same spirit, if $E$ is an $A$-bimodule, the tensor product $E \otimes_A \ldots \otimes_A E$ of $n$ copies of $E$ will be denoted by $E^n$.

1.1 Definition: Let $A$ be a ring and $S$ be an $A$-bimodule. Let $M$ be a right $A$-module and $f : M \to MS$ be an $A$-linear map. So by iteration, we get for each integer $n > 0$ a morphism $f^n : M \to MS^n$. We say that $f$ is nilpotent if every element in $M$ is killed by some power $f^n$ of $f$.

1.2 Lemma: Let $(A, S)$ be a left-flat bimodule. Let $M$ be a right $A$-module and $f : M \to MS$ be an $A$-linear map. Then $f$ is nilpotent if and only if there is a filtration of $M$:

$$0 = M_0 \subset M_1 \subset M_2 \subset \ldots \subset M$$

by right $A$-submodules, such that:

• $M$ is the union of the $M_i$’s
• for every $i > 0$, one has: $f(M_i) \subset M_{i-1}S$.

Proof: If such a filtration exists, then $f$ is clearly nilpotent.

Suppose $f$ is nilpotent. For every integer $n \geq 0$, denote by $M_n$ the kernel of $f^n : M \to MS^n$. By construction we have an increasing sequence

$$0 = M_0 \subset M_1 \subset M_2 \subset M_3 \ldots$$

and $M$ is the union of the $M_i$’s.

Since $S$ is flat on the left, we have, for every $n \geq 0$, an isomorphism:

$$\text{Ker}(f^n : MS \to MS^{n+1}) \simeq \text{Ker}(f^n : M \to MS^n)S$$

and then an equality: $M_{n+1} = f^{-1}(M_nS)$. The result follows. \qed

1.3 The exact category $\mathcal{Nil}(A, S)$ and the space $\text{Nil}(A, S)$.

Let $(A, S)$ be a left-flat bimodule. The pairs $(M, f)$ where $M$ is a right $A$-module and $f : M \to MS$ is a nilpotent morphism form a category denoted by $\mathcal{Nil}(A, S)^\vee$. Let $\mathcal{A}$ be the category of finitely generated projective right $A$-modules. The full subcategory of $\mathcal{Nil}(A, S)^\vee$ generated by pairs $(M, f)$ with $M \in \mathcal{A}$ will be denoted by $\mathcal{Nil}(A, S)$.

If $0 \to (M, f) \to (M', f') \to (M'', f'') \to 0$ is a sequence in $\mathcal{Nil}(A, S)$, we say that this sequence is exact if the following diagram is commutative with exact
With these exact sequences the category $\mathcal{N}il(A, S)$ becomes an exact category in the sense of Quillen and its algebraic $K$-theory $K(\mathcal{N}il(A, S))$ is a well defined infinite loop space (see [Q]).

Actually $\mathcal{N}il$ is a functor from the category of left-flat bimodules to the category of essentially small exact categories and exact functors.

We have two exact functors $M \mapsto (M, 0)$ from $\mathcal{A}$ to $\mathcal{N}il(A, S)$ and $(M, f) \mapsto M$ from $\mathcal{N}il(A, S)$ to $\mathcal{A}$ inducing two maps:

$$K(A) \xrightarrow{F} K(\mathcal{N}il(A, S)) \xrightarrow{G} K(A)$$

where $G$ is a retraction of $F$. Denote by $\mathcal{N}il(A, S)$ the homotopy fiber of $G$. Then $\mathcal{N}il(A, S)$ is an infinite loop space and we have a decomposition:

$$K(\mathcal{N}il(A, S)) \simeq K(A) \times \mathcal{N}il(A, S)$$

Throughout this paper, we’ll consider many categories and functors and, in particular, many exact categories and their abelianizations, where an abelianization of an exact category is defined as follows:

**Definition:** Let $\mathcal{E}$ be an exact category. We say that a category $\mathcal{E}^\vee$ is an abelianization of $\mathcal{E}$ if the following holds:

- $\mathcal{E}^\vee$ is an abelian category
- $\mathcal{E}$ is a fully exact subcategory of $\mathcal{E}^\vee$ i.e. $\mathcal{E}$ is a full subcategory of $\mathcal{E}^\vee$ and, for every sequence $S = (0 \to X \to Y \to Z \to 0)$ in $\mathcal{E}$, $S$ is exact in $\mathcal{E}$ if and only if $S$ is exact un $\mathcal{E}^\vee$
- $\mathcal{E}$ is stable in $\mathcal{E}^\vee$ under extension.

Notice that the Gabriel-Quillen embedding theorem produces an abelianization for every essentially small exact category (see [TT], thm A.7.1 or [K], prop A.2).

Following Waldhausen we consider three situations: the generalized free product case, the generalized Laurent extension case and the generalized polynomial extension case.

In case 1 (i.e. the generalized polynomial extension case), we have a ring $C$ and a $C$-bimodule $S$ which is flat on the left. In this case the ring $R$ is the tensor algebra of $S$:

$$R = C \oplus S \oplus S^2 \oplus S^3 \oplus \ldots$$
In case 2 (i.e. the generalized free product case) we have two pure morphisms of rings $\alpha : C \to A$ and $\beta : C \to B$ and we suppose that $A$ and $B$ are $C$-flat on the left. We denote by $R$ the ring defined by the cocartesian diagram:

$$
\begin{array}{ccc}
C & \xrightarrow{\alpha} & A \\
\downarrow{\beta} & & \downarrow \\
B & \longrightarrow & R
\end{array}
$$

In case 3 (i.e the generalized Laurent extension case) we have two rings $C$ and $A$ and two pure morphisms $\alpha$ and $\beta$ from $C$ to $A$. We suppose that $A$ is $C$-flat on the left via both $\alpha$ and $\beta$ and we denote by $R$ the ring generated by $A$ and an invertible element $t$ with the only relations:

$$\forall c \in C, \quad \alpha(c)t = t\beta(c)$$

So we have a morphism $\gamma : A \to R$ and $\gamma \circ \alpha$ and $\gamma \circ \beta$ are conjugate.

From now on we will consider $\alpha$ and $\gamma$ as inclusions. So in each case $A$, $B$ and $R$ are $C$-bimodules.

We denote by $\mathcal{A}$, $\mathcal{B}$, $\mathcal{C}$ and $\mathcal{R}$ the categories of finitely generated projective right modules over the rings $A$, $B$, $C$ and $R$ respectively. We set also: $\mathcal{D} = \mathcal{C}$ in case 1, $\mathcal{D} = \mathcal{A} \times \mathcal{B}$ in case 2 and $\mathcal{D} = \mathcal{A}$ in case 3. This category is the category of finitely generated projective right modules over the ring $C$ or $A \times B$ or $A$.

The categories $\mathcal{A}$, $\mathcal{B}$, $\mathcal{C}$, $\mathcal{D}$ and $\mathcal{R}$ are contained in the abelian categories $\mathcal{A}^\vee$, $\mathcal{B}^\vee$, $\mathcal{C}^\vee$, $\mathcal{D}^\vee$ and $\mathcal{R}^\vee$ of right-modules over the corresponding rings and these categories are abelianizations of $\mathcal{A}$, $\mathcal{B}$, $\mathcal{C}$, $\mathcal{D}$ and $\mathcal{R}$ respectively. Notice that $\text{Nil}(A,S)^\vee$ is also an abelianization of $\text{Nil}(A,S)$.

We denote by $C_2$ the ring $C$ in case 1 and $C \times C$ in the other cases and also by $\mathcal{C}_2^\vee$ the category of right $C_2$-modules and by $\mathcal{C}_2$ the subcategory of $\mathcal{C}_2^\vee$ generated by finitely generated projective modules. The category $\mathcal{C}_2^\vee$ is also an abelianization of $\mathcal{C}_2$.

We will define the $C_2$-bimodule $S$ and many categories and functors in order to give a common proof of theorems 1, 2 and 3 (at least for the connective part of it).

### 1.4 The functors $s$ and $\sigma$ and the bimodule $S$.

Consider the case $C_2 = C \times C$. Let $\pi_1$ and $\pi_2$ be the two projections $C \times C \to C$. Consider a right $C$-module $M$ and an integer $i \in \{1, 2\}$. The ring $C \times C$ acts on $M$ via $\pi_i$ and becomes a right $C \times C$-module $M^i$. This functor $M \mapsto M^i$ from $\mathcal{C}^\vee$ to $\mathcal{C}_2^\vee$ has an adjoint functor (on both sides) from $\mathcal{C}_2^\vee$ to $\mathcal{C}^\vee$ denoted by $E \mapsto E_i$. The two functors $M \mapsto M^1$ and $M \mapsto M^2$ induce an equivalence of categories from $\mathcal{C}^\vee \times \mathcal{C}^\vee$ to $\mathcal{C}_2^\vee$ and the functors $E \mapsto E_1$ and $E \mapsto E_2$ induce an inverse of it.
The two functors \( s_i : M \mapsto M^i \) from \( \mathcal{C} \) to \( \mathcal{C}_2 \) (and also from \( \mathcal{C}^\vee \) to \( \mathcal{C}_2^\vee \)) are exact and it is the same for they adjoint functors \( \sigma_i : E \mapsto E_i \) from \( \mathcal{C}_2 \) to \( \mathcal{C} \) (and from \( \mathcal{C}_2^\vee \) to \( \mathcal{C}^\vee \)).

So \( s_1 \), \( s_2 \) and \( s = s_1 \oplus s_2 \) are exact functors and their adjoint functors \( \sigma_1 \), \( \sigma_2 \) and \( \sigma = \sigma_1 \oplus \sigma_2 \) are also exact.

In case 1, \( s \) and \( \sigma \) are defined to be identities. Therefore \( s \) and \( \sigma \) are well defined in all cases: \( s \) is an exact functor from \( \mathcal{C} \) to \( \mathcal{C}_2 \) (and also from \( \mathcal{C}^\vee \) to \( \mathcal{C}_2^\vee \)) and \( \sigma \) is an exact functor from \( \mathcal{C}_2 \) to \( \mathcal{C} \) (and also from \( \mathcal{C}_2^\vee \) to \( \mathcal{C}^\vee \)).

Moreover, for every module \( E \) in \( \mathcal{C}_2 \) (or \( \mathcal{C}_2^\vee \)) the module \( \sigma(E) \) is nothing else but the module \( E \) equipped with the \( \mathcal{C} \)-action induced by the identity or the diagonal map from \( C \) to \( C_2 \).

We can do the same for left modules and we have functors \( M \mapsto {}^iM \) and \( E \mapsto {}_iE \). In case of bimodules, we gets functors \( M \mapsto {}^iM^j \) and \( E \mapsto {}_iE_j \). Using these notations we have the following, for every right \( C \times C \)-module \( E \) and left \( C \times C \)-module \( F \):

\[
E \otimes_{C \times C} F = EF = E_1 1F \oplus E_2 2F = \oplus_i E_i iF
\]

In case 1, the \( \mathcal{C}_2 \)-bimodule \( S \) is already defined.

Consider the case 2. Since \( \alpha : C \rightarrow A \) and \( \beta : C \rightarrow B \) are pure morphisms, \( A \) and \( B \) have two complements \( A' \) and \( B' \). These objects are \( \mathcal{C} \)-bimodules and we have two decompositions of \( \mathcal{C} \)-bimodules: \( A = \alpha(C) \oplus A' \) and \( B = \beta(C) \oplus B' \). Then we define the bimodule \( S \) by:

\[
2S_1 = A' \quad 1S_2 = B' \quad 1S_1 = 2S_2 = 0
\]

Consider the case 3. Ring homomorphisms \( \alpha \) and \( \beta \) induce two left \( \mathcal{C} \)-actions on \( A \) and we get two \( \mathcal{C} \)-bimodules \( _\alpha A \) and \( _\beta A \). By doing the same on the right, we get four \( \mathcal{C} \)-bimodules \( _\alpha A_\alpha, \ _\alpha A_\beta, \ _\beta A_\alpha \) and \( _\beta A_\beta \). Moreover, since \( \alpha \) and \( \beta \) are pure morphisms, we have two decompositions of \( \mathcal{C} \)-bimodules:

\[
_\alpha A_\alpha = \alpha(C) \oplus A' \quad _\beta A_\beta = \beta(C) \oplus A''
\]

Then we define the bimodule \( S \) by:

\[
2S_1 = A' \quad 1S_2 = A'' \quad 1S_1 = _\beta A_\alpha \quad 2S_2 = _\alpha A_\beta
\]

Then in the three cases \( S \) is a well defined \( \mathcal{C}_2 \)-bimodule. It is easy to see that \( S \) is flat on the left.

1.5 The categories \( \mathcal{D}, \mathcal{M}^\vee \) and \( \mathcal{V} \) and the functors \( T, F \) and \( \hat{F} \).

We have a functor \( T : \mathcal{D}^\vee \rightarrow \mathcal{R}^\vee \) defined as follows:

- in case 1: \( T(E) = E \otimes_C R = ER \)
- in case 2: \( T(E_A, E_B) = E_A \otimes_A R \oplus E_B \otimes_B R = E_A R \oplus E_B R \)
- in case 3: \( T(E) = E \otimes_A R = ER \)

It is easy to check that \( T \) is an exact functor sending \( \mathcal{D} \) to \( \mathcal{R} \).
Let $E$ be an object in $\mathcal{D}^\vee$, $M$ be an object in $\mathcal{C}^\vee$ and $\varphi : T(E) \to MR$ be a morphism in $\mathcal{R}^\vee$. We say that $\varphi$ is admissible if the following holds:

- $\varphi(E) \subseteq M \oplus MS$ in case 1
- $\varphi(E_A) \subseteq MA$ and $\varphi(E_B) \subseteq MB$ in case 2 (with: $E = (E_A, E_B)$)
- $\varphi(E) \subseteq MA \oplus MtA \subseteq MR$ in case 3.

The set of admissible morphisms $\varphi : T(E) \to MR$ will be denote by $\mathcal{F}(E, M)$.

Following Waldhausen, we define a splitting diagram as a triple $X = (E, M, \varphi)$ with: $E \in \mathcal{D}^\vee$, $M \in \mathcal{C}^\vee$ and $\varphi \in \mathcal{F}(E, M)$.

The splitting diagram $(E, M, \varphi)$ is called a Mayer Vietoris presentation (resp. a splitting module) if $\varphi$ is surjective (resp. bijective). The splitting modules, the Mayer Vietoris presentations and the splitting diagrams define three categories $\mathcal{V}^\vee \subset \mathcal{M}^\vee \subset \mathcal{I}^\vee$. Moreover categories $\mathcal{V}^\vee$ and $\mathcal{I}^\vee$ are abelian.

If we replace $\mathcal{D}^\vee$ and $\mathcal{C}^\vee$ by $\mathcal{D}$ and $\mathcal{C}$, we get three subcategories $\mathcal{V} \subset \mathcal{M} \subset \mathcal{I}$. The correspondences $(E, M, \varphi) \mapsto E$ and $(E, M, \varphi) \mapsto M$ define two functors $\Phi_2 : \mathcal{I} \to \mathcal{D}$ and $\Phi_3 : \mathcal{I} \to \mathcal{C}$ (and also from $\mathcal{I}^\vee$ to $\mathcal{D}^\vee$ and from $\mathcal{I}^\vee$ to $\mathcal{C}^\vee$).

We have an extra functor $\Phi_1$ sending $(E, M, \varphi)$ to the kernel of $\varphi$.

Consider a sequence $S = (0 \to X \to Y \to Z \to 0)$ in $\mathcal{V}$ or in $\mathcal{I}$. We say that this sequence is exact if it is send to an exact sequence under $\Phi_2$ and $\Phi_3$. If $S$ is a sequence in $\mathcal{M}^\vee$, we say that $S$ is exact if it is send to an exact sequence under $\Phi_1$, $\Phi_2$ and $\Phi_3$.

With these exact sequences, $\mathcal{V}$, $\mathcal{M}^\vee$ and $\mathcal{I}$ become exact categories and the inclusions $\mathcal{V} \subset \mathcal{M} \subset \mathcal{I}$ are exact functors. Moreover $\Phi_1 : \mathcal{M}^\vee \to \mathcal{R}$ is an exact functor. In some sense $\mathcal{V}$ is the kernel of the functor $\Phi_1 : \mathcal{M}^\vee \to \mathcal{R}$.

Since $\mathcal{M}^\vee$ is not an abelian category, it will be useful to construct an abelian category $\mathcal{M}^\vee \cap \mathcal{D}$ containing $\mathcal{M}^\vee$. The category $\mathcal{M}^\vee$ is equivalent to the category of tuples $(U, E, M, \mu, \varphi)$ where $(U, E, M)$ is an object of $\mathcal{R} \times \mathcal{D} \times \mathcal{C}$ and $\mu : U \to T(E)$ and $\varphi : T(E) \to MR$ are morphisms in $\mathcal{R}$ such that $\varphi$ is admissible and the morphism $\mu$ is $0$. It is easy to see that $\mathcal{M}^\vee \cap \mathcal{D}$ is abelian and the inclusions $\mathcal{V} \subset \mathcal{M} \subset \mathcal{I}$ extend to functors $\mathcal{V}^\vee \to \mathcal{M}^\vee \cap \mathcal{D}$ and $\mathcal{M}^\vee \cap \mathcal{D} \to \mathcal{I}^\vee$. Moreover the categories $\mathcal{V}^\vee$, $\mathcal{M}^\vee \cap \mathcal{D}$ and $\mathcal{I}^\vee$ are abelianizations of $\mathcal{V}$, $\mathcal{M}^\vee$ and $\mathcal{I}^\vee$ respectively.

We have a functor $F$ from $\mathcal{C}_2 \to \mathcal{D}_\mathcal{V}$ defined as follows:

- in case 1, $F$ is the identity
- in case 2, $F(M) = (\sigma_1(M)A, \sigma_2(M)B) \in \mathcal{D}^\vee$
- in case 3, $F(M) = \sigma_1(M)_A \oplus \sigma_2(M)_B \in \mathcal{D}^\vee$

where $\sigma_A$ and $\beta_A$ are the module $A$ equipped with the $(C, A)$-bimodule structure induced by $\alpha$ and $\beta$ respectively.

This functor $F$ is exact and sends $\mathcal{C}_2$ to $\mathcal{D}$. It has a right adjoint functor $\tilde{F}$ from $\mathcal{D}^\vee$ to $\mathcal{C}_2^\vee$ and we have:
• in case 1, \( \hat{F} \) is the identity
• in case 2, \( \hat{F}(E_A, E_B) = s_1(E_A) \oplus s_2(E_B) \)
• in case 3, \( \hat{F}(E) = s_1(E_\alpha) \oplus s_2(E_\beta) \)

where \( E_\alpha \) and \( E_\beta \) are the module \( E \) equipped with the right \( C \)-module structure induced by \( \alpha \) and \( \beta \) respectively.

In case: \( C_2 = C \times C \), we have another functor \( M \mapsto \tilde{M} \) from \( C_2^\vee \) (or \( C_2 \)) to itself defined by:

\[
M = (M', M'') \implies \tilde{M} = (M'', M')
\]

**1.6 Lemma:** Suppose \( C_2 = C \times C \). Then for every right \( C \times C \)-module \( M \), we have natural isomorphisms:

\[
s\sigma(M) \simeq M \oplus \tilde{M}
\]

\[
\hat{F}F(M) \simeq M \oplus \tilde{M}_S
\]

Moreover the induced projection \( s\sigma(M) \to M \) and the induced injections \( M \to \hat{F}F(M) \) are adjoint to identities.

**Proof:** Let \( M = (M', M'') \) be a module in \( C_2 = C \times C \). We have:

\[
s(\sigma(M)) = s(M' \oplus M'') = s_1(M' \oplus M'' \oplus s_2(M' \oplus M'') \simeq M \oplus (s_1(M'') \oplus s_2(M')) \simeq M \oplus \tilde{M}
\]

In case 2, we have:

\[
\hat{F}F(M) = \hat{F}(M'A, M''B) = (M'(C \oplus A'), M''(C \oplus B'))
\]

\[
\simeq (M', M'') \oplus (M'2S_1, M''1S_2) \simeq M \oplus \tilde{M}_S
\]

In the case 3 we have:

\[
\hat{F}F(M) = \hat{F}(M'A \oplus M''A) = s_1(M'\alpha A_\alpha \oplus M''\beta A_\beta) \oplus s_2(M'\alpha A_\beta \oplus M''\beta A_\alpha)
\]

\[
= s_1(M' \oplus M'2S_1 \oplus M''1S_1) \oplus s_2(M'2S_2 \oplus M'' \oplus M''1S_2)
\]

\[
\simeq M \oplus s_1(\tilde{M}_S) \oplus s_2(\tilde{M}_S) \simeq M \oplus \tilde{M}_S
\]

and the result follows. \( \square \)

**1.7 The module \( M[S] \) and the transformations \( e, \varepsilon \) and \( \tau \).**

For every \( M \in C_2^\vee \), we set:

\[
M[S] = M \oplus MS \oplus MS^2 \oplus \ldots
\]

and \( M[S] \) is a right \( C_2 \)-module. In case 1, \( M[S] \) is isomorphic to \( MR \).

We have a stabilization map \( MS[S] \to M[S] \) induced by the identities \( MSS^i \to MS^{i+1} \).
1.8 Lemma: There exist natural transformations:

\[ e : TF(P) \xrightarrow{\sim} \sigma(P)R \]

\[ \varepsilon : \sigma(\hat{F}(E)[S]) \xrightarrow{\sim} T(E) \]

\[ \tau : \sigma(s(M)[S]) \rightarrow MR \]

for all \( P \in \mathcal{C}_2^\vee \), \( E \in \mathcal{D}^\vee \) and \( M \in \mathcal{C}^\vee \) such that:

- \( e \) is an isomorphism of \( R \)-modules
- \( \varepsilon \) is an isomorphism of \( C \)-modules
- \( \tau \) is an epimorphism of \( C \)-modules and the following diagram is exact (i.e. cartesian and cocartesian):

\[
\begin{array}{ccc}
\sigma s(M) & \rightarrow & \sigma(s(M)[S]) \\
\tau_0 \downarrow & & \downarrow \tau \\
M & \rightarrow & MR
\end{array}
\]

where the horizontal maps are the canonical inclusions and \( \tau_0 \) is adjoint to the identity of \( s(M) \).

Proof: In case 1, it is easy to see that \( e, \varepsilon, \tau \) and \( \tau_0 \) can be chosen to be identities.

In the other cases consider a module \( P \in \mathcal{C}_2^\vee \). So we have two \( C \)-modules \( M = P_1 \) and \( N = P_2 \).

In case 2, we have:

\[ T(F(P)) = T(MA, NB) = MA \otimes_A R \oplus NB \otimes_B R \cong MR \oplus NR \cong (M \oplus N)R = \sigma(P)R \]

and we get the isomorphism \( e \).

In case 3, we have:

\[ T(F(P)) = T(MaA \oplus N_\beta A) \cong MaR \oplus N_\beta R \]

but the multiplication on the left by \( t \) induces an isomorphism of \((C,R)\)-bimodules from \( \beta R \) to \( \alpha R \). Then we have:

\[ T(F(P)) \cong MaR \oplus N_\alpha R = \sigma(P)_\alpha R = \sigma(P)R \]

and we get the isomorphism \( e \).

In order to construct the morphism \( \tau \), we need to give an explicit description of \( R \) as a \( C \)-bimodule.

We set:

\[ _\alpha U_\alpha = A' \quad _\beta U_\beta = B' \quad _\alpha U_\beta = _\beta U_\alpha = 0 \]
in case 2 and:

\[ \alpha U_\alpha = A' \quad \beta U_\beta = tA^{n-1} \quad \alpha U_\beta = A t^{-1} \quad \beta U_\alpha = t A \]

in case 3.

For each sequence \( \Sigma = (i_1, j_1, i_2, j_2, \ldots, i_n, j_n) \) in the set \( \{\alpha, \beta\} \), the ring structure on \( R \) induce for each \( i, j \) the sum of the morphisms \( \Phi(\Sigma) \), for each sequence \( \Sigma = (i_1, j_1, i_2, j_2, \ldots, i_n, j_n) \) such that \( j_k = i_{k+1} \) in the sequence \( \Sigma = (i_1, j_1, i_2, j_2, \ldots, i_n, j_n) \), every element of the image of \( \Phi(\Sigma) \) is reducible. As a consequence the sum of these morphisms is an epimorphism. On the other hand it is easy to see that, for each \( i, j, k \) in \( \{\alpha, \beta\} \), the image of \( \Phi(i, j, k) \) is contained in \( C \oplus_i U_k \). Therefore, if there is some \( k < n \) such that \( j_k = i_{k+1} \) in the sequence \( \Sigma = (i_1, j_1, i_2, j_2, \ldots, i_n, j_n) \), every element of the image of \( \Phi(\Sigma) \) is reducible. As a consequence the sum of the morphisms \( \Phi(\Sigma) \), for each sequence \( \Sigma = (i_1, j_1, i_2, j_2, \ldots, i_n, j_n) \) such that \( j_k \neq i_{k+1} \) for every \( k < n \) is still an epimorphism.

Actually this sum is an isomorphism and we have a description of \( R \) as \( C \)-bimodule:

\[ R = C \oplus \bigoplus_{i_1 U_{j_1} U_{i_2} \ldots i_n U_{j_n}} \]

the sum being taken over all non empty sequences \( (i_1, j_1, i_2, j_2, \ldots, i_n, j_n) \) in \( \{\alpha, \beta\} \) such that \( j_k \neq i_{k+1} \) for all \( k < n \).

This fact was proven in [Wa1], p. 140 (or in [C]) for the case 2 and in [Wa1], p. 150 (with a suggestion of S. Cappell) for the case 3.

Denote by \( f \) (resp. \( g \)) the unique bijection from \( \{1, 2\} \) to \( \{\alpha, \beta\} \) such that \( f(1) = \beta \) (resp. \( g(1) = \alpha \)). Then, because of the definition of \( S \), we have in case 2:

\[ \forall i, j \in \{1, 2\}, \quad i S_j = f(i) U g(j) \]

In case 3, we check that the multiplication by \( t \) or \( 1 \) on the left and by \( t^{-1} \) or \( 1 \) on the right induce for each \( i, j \) in \( \{1, 2\} \) an isomorphism of \( C \)-bimodules \( i S_j \xrightarrow{\sim} f(i) U g(j) \).

Then in cases 2 and 3 we have an isomorphism of \( C \)-bimodules:

\[ R \simeq C \oplus \bigoplus_{i_1 S_{j_1} i_2 S_{j_2} \ldots i_n S_{j_n}} \]

the sum being taken over all non empty sequences \( (i_1, j_1, i_2, j_2, \ldots, i_n, j_n) \) in \( \{1, 2\} \) such that \( j_k = i_{k+1} \) for all \( k < n \). Hence we get an isomorphism of \( C \)-bimodules:

\[ R \simeq C \oplus \bigoplus_{i,j} (i S_j) \oplus \bigoplus_{i,j} (S^2)_{ij} \oplus \bigoplus_{i,j} (S^3)_{ij} \oplus \ldots \simeq C \oplus \bigoplus_{i,j,n > 0} i(S^n)_{ij} \]

So we are able to define the morphism \( \tau \). If \( M \) is a right \( C \)-module we have:

\[ MR \simeq M \bigoplus_{i,j,n > 0} M i (S^n)_{ij} \simeq M \bigoplus_{j,n > 0} (s(M)S^n)_{ij} \simeq M \bigoplus_{n > 0} \sigma(s(M)S^n) \]

But we have:

\[ \sigma(s(M)[S]) = \sigma(s(M) \bigoplus_{n > 0} \sigma(s(M)S^n)) \]
Then we define the morphism $\tau$ to be the identity on the direct sum of the $\sigma(s(M)S^n)$ and the morphism $\tau_0 : \sigma s(M) \rightarrow M$ induced by the adjunction on the first term $\sigma s(M)$.

The last thing to do is to construct the isomorphism $\varepsilon$ in cases 2 and 3.

In case 2 with $E = (E_A, E_B)$, we have:

$$T(E) = E_A \otimes_A R \oplus E_B \otimes_B R \simeq E_A(C \oplus B' \oplus B' A' \oplus B' A' B' \oplus \ldots) \oplus E_B(C \oplus A' \oplus A' B' \oplus A' B' A' \oplus \ldots)$$

$$\simeq E_A \oplus E_B \oplus E_A( \oplus_{j,n>0} 1(S^n)_j) \oplus E_B( \oplus_{j,n>0} 2(S^n)_j)$$

$$\simeq \sigma(\hat{F}(E)) \oplus ( \oplus_{n>0} \sigma(\hat{F}(E)S^n)) \simeq \sigma(\hat{F}(E)[S])$$

which give the isomorphism $\varepsilon$.

In the last case we have:

$$R \simeq C \oplus \bigoplus_{i,j,n>0} 1(S^n)_j \simeq (C \oplus 2S_1)(C \oplus \bigoplus_{j,n>0} 1(S^n)_j) \oplus 2S_2(C \oplus \bigoplus_{j,n>0} 2(S^n)_j)$$

$$\simeq A(C \oplus \bigoplus_{j,n>0} 1(S^n)_j) \oplus A_1(C \oplus \bigoplus_{j,n>0} 2(S^n)_j)$$

and we check that the isomorphism from $R$ to this last module is an isomorphism of $(A, C)$-bimodules. Since $E$ belongs to $\mathcal{A}^\vee$, we have:

$$T(E) \simeq E_\alpha(C \oplus \bigoplus_{j,n>0} 1(S^n)_j) \oplus E_\beta(C \oplus \bigoplus_{j,n>0} 2(S^n)_j)$$

$$\simeq \sigma(\hat{F}(E)) \oplus ( \oplus_{n>0} \sigma(\hat{F}(E)S^n)) \simeq \sigma(\hat{F}(E)[S])$$

which give the isomorphism $\varepsilon$ in this last case.

\[ \square \]

1.9 Remark: We have an explicit description of the morphism $\tau$ and the isomorphism $\varepsilon$.

Consider two modules $M \in \mathcal{C}^\vee$ and $E \in \mathcal{D}^\vee$.

In case 1, set: $\overline{u} = u$ for each $u \in E$.

In case 2, the maps $E_A \rightarrow E_AR$ and $E_B \rightarrow E_BR$ induce a map $\sigma(E) \rightarrow T(E)$ and in case 3, the maps $E_\alpha \rightarrow ER$ and $E_\beta \rightarrow EtR \rightarrow ER$ induce also a map $\sigma(E) \rightarrow T(E)$. Denote by $v \mapsto \overline{v}$ this map.

So we have a morphism $v \mapsto \overline{v}$ from $\sigma(E)$ to $T(E)$ in the three cases.

Denote also by $s \mapsto \overline{s}$ the isomorphism $1S_j \xrightarrow{\sim} f(i)U_{g(j)} \subset R$ in cases 2 or 3 and the identity $S \rightarrow S$ in case 1.

With these notations, we have the following description of $\tau$ and $\varepsilon$:
In case 1, for each integer \( n \geq 0 \), each \( u \in M \), each \( v \in E \) and each sequence \((s_1, s_2, \ldots, s_n)\) in \( S \) we have:

\[
\tau(us_1s_2\ldots s_n) = u \overline{s_1s_2\ldots s_n} \in MR \\
\varepsilon(vs_1s_2\ldots s_n) = v \overline{s_1s_2\ldots s_n} \in T(E)
\]

In case 2 or 3, for each integer \( n \geq 0 \), each sequence \((i_0, i_1, \ldots, i_n)\) in \( \{1, 2\} \), each \( u \in M \), each \( v \in E_{i_0} \) and each sequence \((s_1, s_2, \ldots, s_n)\), with \( s_k \in S_{i_k} \), we have:

\[
\tau(us_1s_2\ldots s_n) = u \overline{s_1s_2\ldots s_n} \in MR \\
\varepsilon(vs_1s_2\ldots s_n) = v \overline{s_1s_2\ldots s_n} \in T(E)
\]

\[1.10 \text{Lemma:} \] There is a natural transformation:

\[ \Lambda : \mathcal{F}(E, M) \longrightarrow \text{Hom}(\hat{F}(E), s(M) \oplus s(M)S) \]

for each \((E, M) \in \mathcal{D}^\vee \times \mathcal{C}^\vee \) with the following properties:

- \( \Lambda \) is injective in case 2 or 3 and bijective in case 1
- for each \((P, M) \in \mathcal{C}^\vee \times \mathcal{C}^\vee \), if \( f \) is the map \( P \longrightarrow \hat{F}(F(P)) \) induced by adjunction, the composite morphism:

\[ \mathcal{F}(F(P), M) \xrightarrow{\Lambda} \text{Hom}(\hat{F}(F(P)), s(M) \oplus s(M)S) \xrightarrow{f^*} \text{Hom}(P, s(M) \oplus s(M)S) \]

is bijective

- for each \( \varphi \in \mathcal{F}(E, M) \), we have a commutative diagram:

\[
\begin{array}{ccc}
\sigma(\hat{F}(E)[S]) & \xrightarrow{g} & \sigma(s(M)[S]) \\
\downarrow\varepsilon & & \downarrow\tau \\
T(E) & \xrightarrow{\varphi} & MR
\end{array}
\]

where \( g \) is the composite morphism:

\[
\sigma(\hat{F}(E)[S]) \xrightarrow{\Lambda(\varepsilon)} \sigma((s(M) \oplus s(M)S)[S]) \xrightarrow{h} \sigma(s(M)[S])
\]

and \( h \) the morphism induced by the identity \( s(M)[S] \longrightarrow s(M)[S] \) and the stabilization map \( s(M)S[S] \longrightarrow s(M)[S] \).

\[\text{Proof:} \] Consider the case 1. We have an isomorphism from \( \text{Hom}_{\mathcal{F}}(ER, MR) \) to \( \text{Hom}_{\mathcal{F}}(E, MR) \) inducing an isomorphism \( \mathcal{F}(E, M) \cong \text{Hom}(E, M \oplus MS) \). and we get the isomorphism \( \Lambda : \mathcal{F}(E, M) \cong \text{Hom}(E, M \oplus MS) = \text{Hom}(\hat{F}(E), s(M) \oplus s(M)S) \).
Consider the case 2. We have \( E = (E_A, E_B) \in \mathcal{A} \times \mathcal{B} \) and we get isomorphisms:
\[
\text{Hom}_\mathcal{A}(T(E), MR) \simeq \text{Hom}_\mathcal{A}(E_A R \oplus E_B R, MR) \simeq \text{Hom}_\mathcal{A}(E_A, MR) \oplus \text{Hom}_\mathcal{A}(E_B, MR)
\]
and then isomorphisms:
\[
\mathcal{F}(E, M) \simeq \text{Hom}(E_A, MA) \oplus \text{Hom}(E_B, MB) \simeq \text{Hom}(E, (MA, MB)) = \text{Hom}(E, F(s(M)))
\]

Consider now the last case. We have:
\[
\text{Hom}_\mathcal{A}(T(E), MR) \simeq \text{Hom}_\mathcal{A}(ER, MR) \simeq \text{Hom}_\mathcal{A}(E, MR)
\]
and then:
\[
\mathcal{F}(E, M) \simeq \text{Hom}(E, MA) \oplus \text{Hom}(E, MB) \simeq \text{Hom}(E, F(s(M)))
\]

Therefore, in case 2 and 3, we have an isomorphism:
\[
\mathcal{F}(E, M) \sim \text{Hom}(E, F(s(M)))
\]

On the other hand, the morphism \( \hat{F} \) induces an injection:
\[
\text{Hom}(E, F(s(M))) \longrightarrow \text{Hom}(\hat{F}(E), \hat{F}(F(s(M)))) \simeq \text{Hom}(\hat{F}(E), s(M) \oplus s(M)S)
\]
(see lemma 1.6) and we get the desired injection
\[
\Lambda : \mathcal{F}(E, M) \longrightarrow \text{Hom}(\hat{F}(E), s(M) \oplus s(M)S)
\]

Let \((P, M)\) be an object in \( C_2 \times \mathcal{C} \). In case 1, the morphism \( P \longrightarrow \hat{F}(F(P)) \) is the identity and the composite map:
\[
\mathcal{F}(F(P), M) \xrightarrow{\Lambda} \text{Hom}(\hat{F}(F(P)), s(M) \oplus s(M)S) \xrightarrow{f^*} \text{Hom}(P, s(M) \oplus s(M)S)
\]

is bijective.

Consider the other cases. Let \( \varphi \in \mathcal{F}(F(P), M) \) be an admissible morphism and \( \alpha : F(P) \longrightarrow F(s(M)) \) be the corresponding morphism (via the isomorphism (*)). Let \( f : P \longrightarrow \hat{F}(F(P)) \) be the morphism adjoint to the identity of \( F(P) \). By adjunction, the composite morphism \( P \xrightarrow{f} \hat{F}(F(P)) \xrightarrow{\alpha} \hat{F}(s(M)) \) is the morphism obtained from \( \alpha \) by adjunction and we have a bijection \( \text{Hom}(F(P), F(s(M))) \simeq \text{Hom}(P, \hat{F}(s(M))) \). Hence we have a bijection:
\[
\mathcal{F}(F(P), M) \simeq \text{Hom}(P, \hat{F}(s(M))) \simeq \text{Hom}(P, s(M) \oplus s(M)S)
\]
which is nothing else but the map \( f^* \circ \Lambda \).

Denote by \((D)\) the diagram of the lemma.

In case 1, \( \varepsilon \) and \( \tau \) are identities and we have: \( g = \varphi \). Hence \((D)\) is commutative.
Consider the other cases. Via the bijection \( \mathcal{F}(E, M) \simeq \text{Hom}(E, F(s(M))) \), the morphism \( \varphi \in \mathcal{F}(E, M) \) corresponds to a morphism \( \hat{\varphi} : E \to F(s(M)) \) and we have a diagram:

\[
\begin{array}{cccc}
\sigma(\hat{F}(E)[S]) & \xrightarrow{\hat{\varphi}} & \sigma(\hat{F}F(s(M))[S]) & \xrightarrow{g_0} & \sigma(s(M)[S]) \\
\varepsilon \downarrow & & \varepsilon \downarrow & \tau \downarrow & \\
T(E) & \xrightarrow{\hat{\varphi}} & T(F(s(M))) & \xrightarrow{\varphi_0} & MR
\end{array}
\]

In this diagram, the square on the left is commutative by naturality and the square on the right \((D_0)\) is the diagram \((D)\) in the case: \( E = F(s(M)) \). Moreover the total square is the diagram \((D)\). Hence, to prove the commutativity of \((D)\) it is enough to prove that \((D_0)\) is commutative.

In \((D_0)\), the morphism \( g_0 \) is induced by the isomorphism \( \hat{F}F(s(M)) \overset{\sim}{\to} s(M) \oplus s(M)S \), the identity \( s(M)[S] \to s(M)[S] \) and the stabilization map \( s(M)S[S] \to s(M)[S] \).

The morphism \( \varphi_0 \) is the composite map:

\[
T(F(s(M))) \overset{\sim}{\to} (MA \oplus MB)R \simeq MR \oplus MR \xrightarrow{a} MR
\]
in case 2 and the composite map:

\[
T(F(s(M))) \overset{\sim}{\to} (MA \oplus MtA)R \simeq MR \oplus MR \xrightarrow{a} MR
\]
in case 3. Hence \( \varphi_0 \) is the composite map:

\[
T(F(s(M))) \overset{\sim}{\to} \sigma s(M)R \xrightarrow{a} MR
\]
where \( a : \sigma s(M) \to M \) is adjoint to the identity of \( s(M) \).

Consider an element \( u \in \hat{F}F(s(M)) \), an integer \( n \geq 0 \), a sequence \( (i_0, i_1, \ldots, i_n) \) in \( \{1, 2\} \) and a sequence \( (s_1, s_2, \ldots, s_n) \) with \( s_k \in i_{k-1}S_{i_k} \). Denote by \( v \) the image of \( u \) under the isomorphism \( \hat{F}F(s(M)) \simeq s(M) \oplus s(M)S \). If \( v \) belongs to \( s(M) \) or to \( s(M)S_{i_0} \), we have, because of remark 1.9, the following:

\[
\varphi_0\varepsilon (us_1s_2 \ldots s_n) = v \overline{s_1} \overline{s_2} \ldots \overline{s_n} = \tau g_0 (us_1s_2 \ldots s_n)
\]
and \((D_0)\) is therefore commutative.

1.11 The functors \( \Phi : \mathcal{N}il(C_2, S)^\vee \to \mathcal{V}^\vee \) and \( \Psi : \mathcal{F}^\vee \to \mathcal{N}il(C_2, S)^\vee \).

Let \( H \) be a module in \( \mathcal{C}_2^\vee \). Because of lemma 1.10, we have an isomorphism:

\[
\zeta : \mathcal{F}(F(H), \sigma(H)) \overset{\sim}{\to} \text{Hom}(H, s\sigma(H) \oplus s\sigma(H)S)
\]
Therefore, for every morphism $\theta : H \rightarrow HS$, we have a unique morphism $\varphi_\theta$ in $\mathcal{F}(F(H), \sigma(H))$ such that $\zeta(\varphi_\theta)$ is the composite morphism:

$$H \xrightarrow{1-\theta} H \oplus HS \xrightarrow{i} sH \oplus sHS$$

where $i : H \rightarrow sH$ is adjoint to the identity. Thus $\Phi(H, \theta) = (F(H), \sigma(H), \varphi_\theta)$ is a well defined split diagram in $\mathcal{F}^\vee$.

1.12 Lemma: The correspondence above induces two equivalences of categories $\Phi : \mathcal{Nil}(C_2, S) \xrightarrow{\sim} \mathcal{V}$ and $\Phi : \mathcal{Nil}(C_2, S)^\vee \xrightarrow{\sim} \mathcal{V}^\vee$.

Moreover there is a functor $\Psi : \mathcal{F}^\vee \rightarrow \mathcal{Nil}(C_2, S)^\vee$ and a morphism of functors $\pi$ from $I\Phi \Psi$ to the identity, where $I : \mathcal{V}^\vee \rightarrow \mathcal{F}^\vee$ is the inclusion, such that the following holds for every $X \in \mathcal{F}^\vee$ (with: $\Psi(X) = (H, \theta)$):

- we have a natural exact sequence in $\mathcal{C}^\vee$:

$$0 \rightarrow \Phi_1(X) \rightarrow \sigma(H) \xrightarrow{\pi} \Phi_3(X)$$

- a splitting diagram $X$ belongs to $\mathcal{M}^\vee$ (resp. to $\mathcal{V}^\vee$) if and only if the morphism $\pi : \Phi \Psi(X) \rightarrow X$ is an epimorphism (resp. an isomorphism).

Remark: Actually, everything works without any flatness condition from subsection 1.4 to 1.11. But this condition is strongly needed for lemma 1.12, essentially for constructing the functor $\Psi$.

Proof of lemma 1.12: Let $(H, \theta)$ be an object of $\mathcal{Nil}(C_2, S)^\vee$. If $\theta = 0$, the morphism $\varphi_0 : T(F(H)) \rightarrow \sigma(H)R$ is nothing else but the isomorphism $e$ defined in lemma 1.8. Therefore $\Phi(H, \theta)$ belongs to $\mathcal{V}^\vee$ in this case.

Suppose $\theta$ is nilpotent. Then, because of lemma 1.2, there is a filtration $0 = H_0 \subset H_1 \subset H_2 \subset \ldots \subset H$ such that $H$ is the union of the $H_i$'s and, for all $i > 0$, $\theta(H_i)$ is contained in $H_{i-1}S$.

On the other hand it is easy to see that the functor $\Phi$ is exact. So we get a filtration:

$$0 = \Phi(H_0, \theta) \subset \Phi(H_1, \theta) \subset \Phi(H_2, \theta) \subset \ldots \subset \Phi(H, \theta)$$

Because each $\Phi(H_i/H_{i-1}, \theta) = \Phi(H_i/H_{i-1}, 0)$ belongs to $\mathcal{V}^\vee$, each $\Phi(H_i, \theta)$ is also in $\mathcal{V}^\vee$ and then $\Phi(H, \theta)$ is a splitting module.

Therefore $\Phi$ is a functor from $\mathcal{Nil}(C_2, S)^\vee$ to $\mathcal{V}^\vee$ and also from $\mathcal{Nil}(C_2, S)$ to $\mathcal{V}$.

Let $X = (E, M, \varphi)$ be a splitting diagram with $E \in \mathcal{F}^\vee$ and $M \in \mathcal{C}^\vee$. Denote by $P$ the module $\hat{F}(E) \in \mathcal{C}^\vee_2$. By composing the morphism $\varphi e : \sigma(P[S]) \rightarrow MR$ with the identity $P[S] = \sigma(P[S])$, we get a $\mathbb{Z}$-linear map $f : P[S] \rightarrow MR$. Denote by $H$ the $\mathbb{Z}$-submodule $f^{-1}(M)$ and by $i$ the inclusion map $H \rightarrow P[S]$.

Because of lemma 1.10, $\varphi$ is determined by a morphism $\psi = \Lambda(\varphi)$ from $P = \hat{F}(E)$ to $s(M) \oplus s(M)S$. Then we have two morphisms $\lambda : P \rightarrow s(M)$ and $\gamma : P \rightarrow s(M)S$ such that: $\psi = \lambda - \gamma$. Moreover the composite map $P[S] = \sigma(P[S]) \xrightarrow{\varphi e} MR$ is equal to: $\tau(\lambda - \gamma)$. 

17
We have:
\[
 u \in H \iff \varphi \varepsilon(u) \in M \iff \tau(\lambda - \gamma)(u) \in M \\
 \iff \forall k \geq 0, \ \tau(\lambda(u_{k+1}) - \gamma u_k)) = 0
\]

But the morphism \( \tau : \sigma(s(M)S^k) \to MR \) is injective for all \( k > 0 \) (see lemma 1.8). Then we have:
\[
 u \in H \iff \forall k \geq 0, \ \lambda(u_{k+1}) = \gamma(u_k)
\]

Since \( \lambda \) and \( \gamma \) are morphisms in \( C_2^\vee \), \( H \) is a \( C_2 \)-module and we have an exact sequence in \( C_2^\vee \):
\[
 0 \to H \xrightarrow{i} P[S] \xrightarrow{\delta} N[S]
\]
where \( N \) is the module \( s(M)S \) and \( \delta \) is the morphism sending \( u = u_0 + u_1 + u_2 + \ldots \) (with \( u_k \in PS^k \) for every \( k \geq 0 \)) to:
\[
 \delta(u_0 + u_1 + u_2 + \ldots) = \sum_{k \geq 0} (\lambda(u_{k+1}) - \gamma(u_k))
\]

If \( U \) is a module in \( C_2^\vee \), we have a morphism \( \theta_U : U[S] \to U[S]S \) sending \( u_0 + u_1 + u_2 + \ldots \in U[S] \) (with \( u_k \in PS^k \) for every \( k \geq 0 \)) to:
\[
 \theta_U(u_0 + u_1 + u_2 + \ldots) = u_1 + u_2 + u_3 + \ldots
\]

Notice that \( \theta_U^k \) sends \( u_0 + u_1 + u_2 + \ldots \in U[S] \) to \( u_k + u_{k+1} + \ldots \) and \( \theta_U \) is nilpotent. Hence \( (U[S], \theta_U) \) belongs to \( \mathcal{N}il(C_2, S)^\vee \).

Consider the following diagram:
\[
\begin{array}{ccc}
 P[S] & \xrightarrow{\delta} & N[S] \\
 \theta_P \downarrow & & \downarrow \theta_N \\
 P[S]S & \xrightarrow{\delta} & N[S]S
\end{array}
\]

Let \( n \geq 0 \) be an integer, \( u \) be an element in \( P \) and \( s_1, s_2, \ldots, s_n \) be elements in \( S \). We have the following:
\[
 n = 0 \implies \delta \theta_P(u) = \theta_N \delta(u) = 0 \\
 n = 1 \implies \delta \theta_P(us_1) = \theta_N \delta(us_1) = -\gamma(u)s_1 \\
 n > 1 \implies \delta \theta_P(us_1 \ldots s_n) = \theta_N \delta(us_1 \ldots s_n) = \lambda(u)s_1 \ldots s_n - \gamma(u)s_1 \ldots s_n
\]
and the diagram \((D)\) is commutative.
Since $S$ is flat on the left, $\mathcal{N}il(C_2, S)^\vee$ is an abelian category and there is a unique nilpotent morphism $\theta : H \to HS$ such that the following sequence is exact in $\mathcal{N}il(C_2, S)^\vee$:

$$0 \to (H, \theta) \overset{i}{\to} (P[S], \theta_P) \overset{\delta}{\to} (N[S], \theta_N)$$

Therefore $\Psi(X) = (H, \theta)$ is a well defined object in $\mathcal{N}il(C_2, S)^\vee$ and we get the desired functor $\Psi : \mathcal{S}^\vee \to \mathcal{N}il(C_2, S)^\vee$.

Consider the splitting diagram $\Phi \Psi(X) = (F(H), \sigma(H), \varphi_\theta)$. The morphism $\varphi_\theta$ corresponds to the composite morphism $H \overset{1-\theta}{\to} H \oplus HS \to s\sigma(H) \oplus s\sigma(H)S$. We have to construct a morphism $\pi : \Phi \Psi(X) \to X$ in $\mathcal{S}^\vee$. This morphism is given by two morphisms $\pi_0 : F(H) \to E$ and $\pi_1 : \sigma(H) \to M$.

For each $u \in H$ we set: $\pi'_0(u) = u_0$, with $i(u) = u_0 + u_1 + \ldots$ and $u_k \in PS^k$ for all $k$. So we have two morphisms $\pi'_0 : H \to \hat{F}(E)$ and $\lambda \pi'_0 : H \to s(M)$ and, by adjunction, two morphisms $\pi_0 : F(H) \to E$ and $\pi_1 : \sigma(H) \to M$.

For $u \in H$, with: $i(u) = u_0 + u_1 + \ldots$, we have:

$$\psi \pi'_0(u) = \psi(u_0) - \gamma(u_0) = \lambda(u_0) - \lambda(u_1) = \lambda \pi'_0(u) - \lambda \pi'_0 \theta(u) = \lambda \pi'_0(1-\theta)(u)$$

and the following diagram is commutative:

\[
\begin{array}{ccc}
H & \overset{\psi_0}{\to} & s\sigma(H) \oplus s\sigma(H)S \\
\pi'_0 \downarrow & & \pi_1 \downarrow \\
P & \overset{\psi}{\to} & s(M) \oplus s(M)S
\end{array}
\]

Therefore the two morphisms $\pi_0 : F(H) \to E$ and $\pi_1 : \sigma(H) \to M$ induce a well defined morphism $\pi : \Phi \Psi(X) \to X$ and we get a commutative diagram:

\[
\begin{array}{ccc}
T(F(H)) & \overset{\varphi_\theta}{\sim} & \sigma(H)R \\
\pi_0 \downarrow & & \pi_1 \downarrow \\
T(E) & \overset{\varphi}{\to} & MR
\end{array}
\]

We have an exact sequence in $\mathcal{S}^\vee$:

$$0 \to \Phi_1(X) \overset{\mu}{\to} T(E) \overset{\varphi}{\to} MR$$

19
and then an exact sequence in $\mathcal{C}^\lor$:

$$0 \longrightarrow \Phi_1(X) \xrightarrow{\varepsilon^{-1}_1} \sigma(P[S]) \xrightarrow{\Phi} MR$$

Therefore we have a commutative diagram in $\mathcal{C}^\lor$ with exact lines:

$$
\begin{array}{c}
0 \longrightarrow \\
| \downarrow \epsilon_i | \downarrow j \\
0 \longrightarrow \\
\end{array}
\begin{array}{cccc}
0 & \longrightarrow & \Phi_1(X) & \longrightarrow & \sigma(H) & \longrightarrow & M & \\
\varepsilon & & \pi_1 & & \sigma(P[S]) & \longrightarrow & MR & \\
\end{array}
$$

where $j : M \longrightarrow MR$ is the inclusion, and the top line of this diagram is the desired exact sequence.

We have the following equivalences:

$$X \in \overline{\mathcal{M} \mathcal{V}} \iff$$

the morphism $\varphi : T(E) \longrightarrow MR$ is surjective

$\iff$ the image of $\varphi$ contains $M$

$\iff$ the image of $\sigma(P[S]) \longrightarrow MR$ contains $M$

$\iff$ $\sigma(H) \xrightarrow{\pi_0} \sigma(P) \xrightarrow{\lambda'} M$ is surjective

where $\lambda'$ is adjoint to $\lambda$. Therefore $X$ belongs to $\overline{\mathcal{M} \mathcal{V}}$ if and only if the morphism $\pi_1 : \sigma(H) \longrightarrow M$ is surjective.

Suppose $X$ belongs to $\overline{\mathcal{M} \mathcal{V}}$. Let $E'$ be the image of $\pi_0 : F(H) \longrightarrow E$. Because of the diagram above, $T(E')$ contains the image of $\mu : \Phi_1(X) \longrightarrow T(E)$ and the image of $\varepsilon i : \sigma(H) \longrightarrow T(E)$. But $T(E')$ is a $R$-submodule of $T(E)$ and $\varphi(T(E'))$ is a $R$-submodule of $MR$ containing $M$. Therefore $\varphi : T(E') \longrightarrow MR$ is surjective and $T(E')$ contains the kernel $\Phi_1(X)$ of $\varphi$. Hence we have: $T(E') = T(E)$ and then: $E' = E$.

Consequently, if $X$ belongs to $\overline{\mathcal{M} \mathcal{V}}$, $\pi_1 : \sigma(H) \longrightarrow M$ and $\pi_0 : F(H) \longrightarrow E$ are surjective and $\pi : \Phi \Psi(X) \longrightarrow X$ is an epimorphism (in $\mathcal{S}^\lor$). Conversely, if $\pi : \Phi \Psi(X) \longrightarrow X$ is an epimorphism, $\pi_1 : \sigma(H) \longrightarrow M$ is surjective and $X$ belongs to $\overline{\mathcal{M} \mathcal{V}}$.

Suppose $X$ is in $\mathcal{V}^\lor$. Then $\pi_0$ and $\pi_1$ are epimorphisms. Because of the exact sequence:

$$0 \longrightarrow \Phi_1(X) \longrightarrow \sigma(H) \xrightarrow{\pi_1} M$$

the morphism $\pi_1 : \sigma(H) \longrightarrow M$ is an isomorphism. Therefore in the diagram $(D_X)$, $\pi_0$ and $\varphi$ are isomorphisms and $\pi : \Phi \Psi(X) \longrightarrow X$ is an isomorphism too. As a
consequence, the functor $\Phi$ induces two equivalences of categories $\Nil(C_2, S) \rightarrow \mathcal{V}$ and $\Nil(C_2, S)^{\vee} \rightarrow \mathcal{V}^{\vee}$.

Conversely, if $\pi$ is an isomorphism, $\pi_0$ and $\pi_1$ are isomorphisms and $\varphi$ is an isomorphism too. Therefore $X$ belongs to $\mathcal{V}^{\vee}$. 

1.13 Lemma: Let $(A, S)$ be a left-flat bimodule and $X = (M, \theta)$ be an object in $\Nil(A, S)^{\vee}$. Let $V$ be a finitely generated projective right $A$-module and $f : V \rightarrow M$ be a morphism. Then there exist an object $Y = (M', \theta') \in \Nil(A, S)$, a split injective morphism $f' : V \rightarrow M'$ and a morphism $g : Y \rightarrow X$ making the following diagram commutative:

\[
\begin{array}{ccc}
V & \xrightarrow{f'} & M' \\
\downarrow & & \downarrow g \\
V & \xrightarrow{f} & M
\end{array}
\]

Proof: Denote by $\mathcal{A}^{\vee}$ the category of right $A$-modules and $\mathcal{A} \subset \mathcal{A}^{\vee}$ the category of finitely generated projective modules in $\mathcal{A}^{\vee}$. Because of lemme 1.2 there is a filtration:

\[0 = M_0 \subset M_1 \subset M_2 \subset \ldots\]

of $M$ by $A$-modules such that $M$ is the union of the $M_i$’s and $\theta(M_i) \subset M_{i-1}S$ for every $i > 0$. Since $V$ is finitely generated, there is an integer $n > 0$ such that $M_n$ contains the image of $f : V \rightarrow M$.

Then we’ll construct modules $F_i \in \mathcal{A}$, morphisms $h_i : F_i \rightarrow M_i$ for $i = 0, 1, \ldots, n$ and morphisms $\theta' : F_i \rightarrow F_{i-1}S$ for $i = 1, 2, \ldots, n$ such that:

- $F_n = V$, $F_0 = 0$ and $h_n = f$
- for each $i = 1, 2, \ldots, n$, the following diagram is commutative:

\[
\begin{array}{ccc}
F_i & \xrightarrow{h_i} & M_i \\
\downarrow \theta' & & \downarrow \theta \\
F_{i-1}S & \xrightarrow{h_{i-1}} & M_{i-1}S
\end{array}
\]

Let $p$ be an integer with $0 \leq p \leq n$. Denote by $H(p)$ the following property:

- There exist modules $F_i \in \mathcal{A}$ and morphisms $h_i : F_i \rightarrow E_i$ for $i = p, \ldots, n$ and also morphisms $\theta' : F_i \rightarrow F_{i-1}S$ for $i = p + 1, \ldots, n$ such that $F_n = V$, $h_n = f$, the diagram $(D_i)$ is commutative for $i = p + 1, \ldots, n$ and $F_0 = 0$ (if $p = 0$).
This property is clearly true if $p = n$. Suppose $H(p)$ is true with $p > 0$ and consider the composite morphism $\lambda : F_p \rightarrow M_p \xrightarrow{\theta} M_{p-1}S$. If $p = 1$, this morphism is trivial and we set: $F_0 = 0$. Therefore the property $H(p - 1) = H(0)$ is true.

Consider the case $p > 1$. Since $F_p$ is finitely generated, $M_{p-1}$ contains a finitely generated submodule $M'$ such that: $\lambda(F_p) \subset M'$. Let $F_{p-1}$ be a module in $\mathcal{A}$ and $\mu : F_{p-1} \rightarrow M'$ be an epimorphism. Since $F_p$ is projective the morphism $F_p \rightarrow M'S$ factorizes through $F_{p-1}S$ and we have a commutative diagram:

\[
\begin{array}{ccc}
F_p & \xrightarrow{\theta'} & F_{p-1}S \\
\downarrow & & \downarrow \\
F_p & \xrightarrow{\lambda} & M'S
\end{array}
\]

So we define the morphism $h_{p-1}$ as the composite map: $F_{p-1} \xrightarrow{\mu} M' \subset M_{p-1}$ and we have the property $H(p - 1)$.

By induction we obtain the property $H(0)$ and all the data are constructed.

Then we set: $M' = F_0 \oplus F_1 \oplus \ldots \oplus F_n$. The morphisms $h_i$ induce a morphism $g : M' \rightarrow M$ and the morphisms $\theta' : F_i \rightarrow F_{i-1}S$ induce a morphism $\theta' : M' \rightarrow M'S$. The lemma is now easy to check. \(\square\)

Denote by $\mathcal{R}'$ the full subcategory of $\mathcal{R}$ generated by modules on the form $U = VR$ with $V \in \mathcal{C}$. This category is exact and cofinal in $\mathcal{R}$, that is, for each module $M \in \mathcal{R}$, there is a module $M' \in \mathcal{R}$ such that $M \oplus M'$ belongs to $\mathcal{R}'$.

**1.14 Lemma:** Let $X$ be a split diagram in $\mathcal{D}^\vee$, $V$ be a module in $\mathcal{R}'$ and $f : V \rightarrow \Phi_1(X)$ be a morphism in $\mathcal{M}^\vee$. Then there exist an object $Y \in \mathcal{M}^\vee$, a morphism $g : Y \rightarrow X$ in $\mathcal{D}^\vee$ and an isomorphism $\varepsilon : V \xrightarrow{\sim} \Phi_1(Y)$ such that the following diagram is commutative:

\[
\begin{array}{ccc}
V & \xrightarrow{\varepsilon} & \Phi_1(Y) \\
\downarrow & & \downarrow \\
V & \xrightarrow{f} & \Phi_1(X)
\end{array}
\]

Moreover, if $X$ belongs to $\mathcal{M}^\vee$, the morphism $g$ can be chosen to be an epimorphism in $\mathcal{D}^\vee$.

**Proof:** The split diagram $X$ is a triple $(E, M, \varphi)$ with $E \in \mathcal{D}^\vee$ and $M \in \mathcal{C}^\vee$. Since $V$ belongs to $\mathcal{R}'$, there is a module $W \in \mathcal{C}$ such that: $V = WR$ and we get a morphism
$f' : W \to \Phi_1(X)$ in $\mathcal{C}$.  

Denote by $K = (H, \theta)$ the object $\Psi(X) \in \mathcal{N}(\mathcal{C}_2, S)$. Because of lemma 1.12, we have an exact sequence:

$$0 \to \Phi_1(X) \xrightarrow{\mu} \sigma(H) \xrightarrow{\pi} M$$

and the morphism $\mu f' : W \to \sigma(H)$ has an adjoint $\lambda : s(W) \to H$. Because of lemma 1.13, there are an object $K' = (H', \theta') \in \mathcal{N}(\mathcal{C}_2, S)$, a morphism $h : K' \to K$ and a split injective morphism $\lambda' : s(W) \to H'$ making the following diagram commutative:

$$s(W) \xrightarrow{\lambda'} H'$$

$$\downarrow \quad h \quad \downarrow$$

$$s(W) \xrightarrow{\lambda} H$$

The morphism $\tilde{\lambda}' : W \to \sigma(H')$ adjoint to $\lambda'$ is still split injective and we get a commutative diagram with exact lines:

$$0 \to W \xrightarrow{\tilde{\lambda}'} \sigma(H') \xrightarrow{\pi'} M' \to 0$$

$$\downarrow f' \quad \downarrow h \quad \downarrow$$

$$0 \to \Phi_1(X) \xrightarrow{\mu} \sigma(H) \xrightarrow{\pi} M$$

where $M'$ is the cokernel of $\tilde{\lambda}'$.

We have now an object $Y' = \Phi(K') = (F(H'), \sigma(H'), \varphi') \in \mathcal{V}$, an object $Y = (F(H'), M', \pi'\varphi) \in \mathcal{M}$ and an epimorphism $u : Y' \to Y$. But the morphism $\Phi(K') \to \Phi(K) \xrightarrow{\pi} X$ vanishes on the kernel of $u$ and factorizes by a morphism $g : Y \to X$. So we have morphisms $Y' \to Y \to X$ inducing a commutative
Hence, we get an isomorphism $\varepsilon : V = WR \longrightarrow \Phi_1(Y)$ and a commutative diagram:

$$
\begin{array}{ccccccccc}
0 & \longrightarrow & 0 & \longrightarrow & T(F(H')) & \longrightarrow & \sigma(H') \mathcal{R} & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \pi' & & \downarrow \\
0 & \longrightarrow & WR & \longrightarrow & T(F(H')) & \longrightarrow & M' \mathcal{R} & \longrightarrow & 0 \\
\downarrow f & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \longrightarrow & \Phi_1(X) & \longrightarrow & T(E) & \longrightarrow & MR & & \\
\end{array}
$$

Suppose $X$ belongs to $\mathcal{M} \mathcal{V}$. Because of lemma 1.12, the morphism $\pi : \Phi \Psi(X) \longrightarrow X$ is an epimorphism in $\mathcal{S} \vee$ inducing two epimorphisms $F(H) \longrightarrow E$ and $\sigma(H) \longrightarrow M$.

Since $E$ is finitely generated, $H$ contains a finitely generated $C_2$-submodule $H_0 \subset H$ such that the composite morphism $F(H_0) \longrightarrow F(H) \longrightarrow E$ is an epimorphism. Therefore there exist a module $P \in \mathcal{C}$ and a morphism $u : s(P) \longrightarrow H$ such that the image of $u$ contains the submodule $H_0$. Because of lemma 1.13, there are an object $K' = (H', \theta') \in \mathcal{M} \mathcal{d}(C_2, S)$, a morphism $h : K' \longrightarrow K$ and a split injective morphism $\lambda' \oplus u' : s(W) \oplus s(P) \longrightarrow H'$ making the following diagram commutative:

$$
\begin{array}{cccccc}
s(W) \oplus s(P) & \xrightarrow{\lambda' \oplus u'} & H' \\
\downarrow & & \downarrow h \\
s(W) \oplus s(P) & \xrightarrow{\lambda \oplus u} & H
\end{array}
$$

Therefore the composite morphism $F(H') \xrightarrow{h} F(H) \longrightarrow E$ is an epimorphism.
If we continue the construction above by using this morphism \( h : K' \to K \), we get a morphism \( g : Y \to X \) such that the morphism \( \Phi_2(Y) \to \Phi_2(X) \) is isomorphic to the morphism \( F(H') \to E \) which is an epimorphism. Hence \( \Phi_2(Y) \to \Phi_2(X) \) is also an epimorphism. On the other hand, we have a commutative diagram:

\[
\begin{array}{ccc}
T(\Phi_2(Y)) & \longrightarrow & \Phi_3(Y)R \\
\downarrow & & \downarrow \\
T(E) & \varphi \longrightarrow & MR
\end{array}
\]

where \( \varphi : T(E) \to MR \) is surjective. Then \( \Phi_3(Y)R \to MR \) is surjective and \( \Phi_3(Y) \to M \) is surjective too. The result follows.

\[\square\]

2. Algebraic K-theory of categories \( \mathcal{V} \) and \( \mathcal{MV} \).

2.1 About Waldhausen K-theory.

A Waldhausen category is a category with a zero object and two subcategories: the category of cofibrations and the category of (weak-)equivalences. These categories have to satisfy certain conditions (see [Wa2]). Waldhausen associates to any essentially small Waldhausen category \( \mathcal{C} \) an infinite loop space \( K(\mathcal{C}) \) and \( K \) (called the Waldhausen K-theory functor) is a functor from the category of essentially small Waldhausen categories to the category of infinite loop spaces.

An exact category \( \mathcal{E} \) may be considered as a Waldhausen category, where a cofibration is an admissible monomorphism of \( \mathcal{E} \) (i.e. a morphism \( f \) appearing in an exact sequence \( 0 \to X \xrightarrow{f} Y \to Z \to 0 \) in \( \mathcal{E} \)) and an equivalence is an isomorphism in \( \mathcal{E} \). Moreover, if \( \mathcal{E} \) is essentially small, we have a natural homotopy equivalence from the Quillen K-theory of \( \mathcal{E} \) to the Waldhausen K-theory of \( \mathcal{E} \).

To every exact category \( \mathcal{E} \) we can associate the following category \( \mathcal{E}_* \):

The objects of \( \mathcal{E}_* \) (called the \( \mathcal{E} \)-complexes) are the complexes:

\[
C = \left( \ldots \xrightarrow{d} C_n \xrightarrow{d} C_{n-1} \xrightarrow{d} C_{n-2} \xrightarrow{d} \ldots \right)
\]

where each \( C_n \) is an object of \( \mathcal{E} \) and each \( d \) is a morphism of \( \mathcal{E} \) such that the sum \( \oplus C_n \) exists in \( \mathcal{E} \) and each morphism \( d \) is zero.

The morphisms in this category are morphisms respecting degrees and differentials. A sequence \( 0 \to X \to Y \to Z \to 0 \) in \( \mathcal{E}_* \) is said to be exact if it induces an exact sequence in \( \mathcal{E} \) on each degree. With these exact sequences, \( \mathcal{E}_* \) becomes an exact category.
If \( \mathcal{E} \) is the category of right modules (resp. the category of finitely generated projective right modules) over a ring \( A \), the \( \mathcal{E} \)-complexes are called \( A \)-complexes (resp. finite \( A \)-complexes).

Suppose \( \mathcal{E} \) is an exact subcategory of an abelian category \( \mathcal{E}^\vee \). Then \( \mathcal{E}_* \) is a Waldhausen category, where cofibrations are admissible monomorphisms and equivalences are morphisms inducing an isomorphism in homology (where homologies are computed in \( \mathcal{E}^\vee \)). Moreover \( \mathcal{E}_* \) is saturated and has a cylinder functor satisfying the cylinder axiom (in the sense of Waldhausen [Wa2]). We have the following result ([Wa2], [We]):

**2.2 Gillet-Waldhausen theorem:** Let \( \mathcal{E} \) be an essentially small exact category contained in an abelian category \( \mathcal{E}^\vee \). Suppose \( \mathcal{E} \) is stable in \( \mathcal{E}^\vee \) by kernel of epimorphisms. Then the inclusion \( \mathcal{E} \subset \mathcal{E}_* \) of Waldhausen categories induces a homotopy equivalence in K-theory.

Let \( \mathcal{E} \) be an essentially small exact category and \( C \) and \( C' \) be two \( \mathcal{E} \)-complexes. For each integer \( n \), we set:

\[
\text{Hom}(C, C')_n = \prod_p \text{Hom}_\mathcal{E}(C_p, C'_{n+p})
\]

and \( \text{Hom}(C, C') \) is a graded \( \mathbb{Z} \)-module. We have on \( \text{Hom}(C, C') \) a natural differential \( d \) of degree \(-1\) defined by:

\[
\forall f \in \text{Hom}(C, C')_n, \quad d(f) = d \circ f - (-1)^n f \circ d
\]

An element of \( \text{Hom}(C, C')_n \) is called a linear map of degree \( n \), a cycle in \( \text{Hom}(C, C')_n \) is called a morphism of degree \( n \) and a boundary of \( \text{Hom}(C, C')_n \) is called a homotopy of degree \( n \). The morphisms of degree 0 are the morphisms in the category \( \mathcal{E}_* \).

In this category, we have also a notion of \( n \)-cone:

Consider a morphism \( f : X \rightarrow Y \) in \( \mathcal{E}_* \) and an integer \( n \in \mathbb{Z} \). We set: \( C = X \oplus Y \). So we have four linear maps: \( i : Y \rightarrow C, \quad p : C \rightarrow X, \quad r : C \rightarrow Y \) and \( s : X \rightarrow C \).

The map \( i \) is an injection, \( p \) is a projection, \( r \) is a retraction of \( i \) and \( s \) is a section of \( p \). There is a unique way to modify degrees and differentials on \( C \) such that the following holds:

\[
\partial^i = n \quad \partial^r = -n \quad \partial^p = -1 - n \quad \partial^s = 1 + n
\]

\[
d(i) = 0 \quad d(p) = 0 \quad d(r) = -(-1)^n fp \quad d(s) = if
\]

With these new degrees and differentials, \( C \) is an \( \mathcal{E} \)-complex called the \( n \)-cone of \( f \).

If \( n = 0 \), \( C \) is the classical mapping cone, the map \( i : Y \rightarrow C \) is a cofibration in \( \mathcal{E}_* \) and we have an exact sequence in \( \mathcal{E}_* \):

\[
0 \rightarrow X \rightarrow T(f) \rightarrow C \rightarrow 0
\]

where \( T(f) \) is the cylinder of \( f \).

If \( n = -1 \), the map \( p : C \rightarrow X \) is also a morphism in \( \mathcal{E}_* \).
Let \( F : \mathcal{A} \to \mathcal{B} \) be an exact functor between two Waldhausen categories. We say that \( F \) has the approximation property if the following holds:

- (App1) a morphism in \( \mathcal{A} \) is an equivalence if and only if its image under \( F \) is an equivalence
- (App2) for every \((X,Y) \in \mathcal{A} \times \mathcal{B}\) and every morphism \( f : F(X) \to Y \), there exist a morphism \( \alpha : X \to X' \) in \( \mathcal{A} \) and a commutative diagram in \( \mathcal{B} \):

\[
\begin{array}{ccc}
F(X) & \xrightarrow{f} & Y \\
\downarrow \alpha & & \downarrow \\
F(X') & \xrightarrow{f'} & Y
\end{array}
\]

where \( f' \) is an equivalence. We have the following theorem of Waldhausen ([Wa2]):

**2.3 Waldhausen approximation theorem:** Let \( F : \mathcal{A} \to \mathcal{B} \) be an exact functor between two essentially small saturated Waldhausen categories. Suppose \( \mathcal{A} \) has a cylinder functor satisfying the cylinder axiom and \( F \) has the approximation property. Then \( F \) induces a homotopy equivalence in K-theory.

**2.4 Lemma:** The functor \( \Phi_2 \times \Phi_3 : \mathcal{MV} \to \mathcal{D} \times \mathcal{C} \) induces a homotopy equivalence in K-theory:

\[
K(\mathcal{MV}) \sim \to K(\mathcal{D} \times \mathcal{C}) = K(\mathcal{D}) \times K(\mathcal{C})
\]

**Proof:** The proof will be done by using Waldhausen K-theory.

The three exact categories \( \mathcal{MV} \), \( \mathcal{D} \) and \( \mathcal{C} \) are contained in the abelian categories \( \mathcal{MV}^\vee \), \( \mathcal{D}^\vee \) and \( \mathcal{C}^\vee \) respectively. Moreover each of these exact categories are closed by kernel of epimorphisms in the corresponding abelian categories. Therefore, because of Gillet-Waldhausen theorem, it’s enough to prove that the functor \( \Phi_2 \times \Phi_3 : \mathcal{MV}_s \to \mathcal{D}_s \times \mathcal{C}_s \) induces a homotopy equivalence in K-theory.

By replacing the category of equivalences of \( \mathcal{MV}_s \) by the category of morphisms \( f : X \to Y \) inducing a homology equivalence \( \Phi_2(X) \sim \to \Phi_2(Y) \) we get a new Waldhausen category denoted by \( \mathcal{MV}_s' \).

Denote also by \( \mathcal{MV}_s^0 \) the Waldhausen subcategory of \( \mathcal{MV}_s \) of objects \( X \) with acyclic \( \Phi_2(X) \). Because of the fibration theorem (see [Wa2]), the sequence:

\[
\mathcal{MV}_s^0 \to \mathcal{MV}_s \to \mathcal{MV}_s'
\]

induces a fibration in K-theory.

Denote by \( \mathcal{D}_s^0 \) the Waldhausen subcategory of \( \mathcal{D}_s \) of acyclic complexes in \( \mathcal{D}_s \). Since each morphism in \( \mathcal{D}_s^0 \) is an equivalence, \( \mathcal{D}_s^0 \) has trivial K-theory. We have a
where each line induces a fibration in K-theory. Therefore it will be enough to prove that functors \( \Phi_2 : \mathcal{M}V_*^\prime \to \mathcal{D}_s \) and \( \Phi_2 \times \Phi_3 : \mathcal{M}V_*^0 \to \mathcal{D}_s^0 \times \mathcal{C}_s \) induce homotopy equivalences in K-theory or, equivalently, that \( \Phi_2 : \mathcal{M}V_*^\prime \to \mathcal{D}_s \) and \( \Phi_3 : \mathcal{M}V_*^0 \to \mathcal{C}_s \) induce homotopy equivalences in K-theory.

Because of the approximation theorem of Waldhausen, in order to prove that \( \Phi_2 : \mathcal{M}V_*^\prime \to \mathcal{D}_s \) and \( \Phi_3 : \mathcal{M}V_*^0 \to \mathcal{C}_s \) induce a homotopy equivalence in K-theory, it’s enough to show that these two functors have the approximation property.

The property (App1) is easy to check. Then the last thing to do is to show that \( \Phi_2 : \mathcal{M}V_*^\prime \to \mathcal{D}_s \) and \( \Phi_3 : \mathcal{M}V_*^0 \to \mathcal{C}_s \) have the property (App2).

Consider an object \( X \in \mathcal{M}V_*^\prime \), an object \( F \in \mathcal{D}_s \) and a morphism \( f : \Phi_2(X) \to F \) in \( \mathcal{D}_s \). The object \( X \) is a triple \( X = (E, M, \varphi) \) where \( E \) is a \( \mathcal{D} \)-complex, \( M \) is a \( \mathcal{C} \)-complex and \( \varphi \) is an element in \( \mathcal{P}(E, M) \) inducing a surjective morphism \( T(E) \to MR \). So \( f \) is a morphism from \( E \) to \( F \) in \( \mathcal{D}_s \).

Denote by \( E_1 \) the \(-1\)-cone of \( f \). So we have linear maps \( i : F \to E_1, \; p : E_1 \to E, \; r : E_1 \to F \) and \( s : E \to E_1 \). The map \( p \) is an epimorphism in \( \mathcal{D}_s \), \( i \) is a morphism of degree \(-1\) and we have:

\[
d(s) = if \quad d(r) = fp
\]

Consider the triple \((E_1, M, \varphi p)\). Since \( p \) is an epimorphism, this triple is an object \( X_1 \in \mathcal{M}V_* \) and we have a morphism \( g : X_1 \to X \). Denote by \( Y \) the 0-cone of \( g \). We have a cofibration \( j : X \to Y \) and four linear maps: \( j : E \to \Phi_2(Y), \; q : \Phi_2(Y) \to E_1, \; \rho : \Phi_2(Y) \to E \) and \( \sigma : E_1 \to \Phi_2(Y) \). Moreover we have:

\[
d(\sigma) = jp \quad d(\rho) = -pq
\]

Consider the linear map \( g = f \rho + rq \). The differential \( d(g) \) vanishes and \( g \) is a morphism from \( \Phi_2(Y) \) to \( F \). It is easy to see that \( g \) is surjective and its kernel is isomorphic to the 0-cone of the identity of \( E \). Moreover we have: \( gj = f \). Therefore
$g : \Phi_2(Y) \to F$ is a homology equivalence and the following diagram is commutative:

\[
\begin{array}{ccc}
\Phi_2(X) & \xrightarrow{f} & F \\
\downarrow j & & \downarrow = \\
\Phi_2(Y) & \xrightarrow{g} & F
\end{array}
\]

Then the functor $\Phi_2 : \mathcal{MV}_* \to \mathcal{D}_*$ has the property (App2) and $\Phi_2 : \mathcal{MV}'_* \to \mathcal{D}_*$ induces a homotopy equivalence in K-theory.

Consider an object $X \in \mathcal{MV}'_0$, an object $N \in \mathcal{C}_*$ and a morphism $f : \Phi_3(X) \to N$ in $\mathcal{C}_*$. The object $X$ is a triple $(E, M, \varphi)$ where $E$ is an acyclic $\mathcal{D}$-complex, $M$ is a $\mathcal{C}$-complex and $\varphi$ is an element in $\mathcal{F}(E, M)$ inducing a surjective morphism $T(E) \to MR$. So $f$ is a morphism from $M$ to $N$.

Let $U$ be the $-1$-cone of the identity of $N$. Then $U$ is acyclic and we have an epimorphism $p : U \to N$. Consider the composite morphism:

$$\varphi' : T(Fs(U)) \xrightarrow{p} T(Fs(N)) \xrightarrow{\sigma s(N)R} NR$$

This morphism is surjective and the triple $(E \oplus Fs(U), N, f \varphi \oplus \varphi')$ is an object $Y$ in $\mathcal{MV}'_0$. Moreover we have a morphism $g : X \to Y$ inducing the inclusion $E \subset E \oplus Fs(U)$ and the morphism $f : M \to N$, making the following diagram commutative:

\[
\begin{array}{ccc}
\Phi_3(X) & \xrightarrow{f} & N \\
\downarrow g & & \downarrow = \\
\Phi_3(Y) & \xrightarrow{=} & N
\end{array}
\]

Hence $\Phi_3 : \mathcal{MV}'_0 \to \mathcal{C}_*$ has the property (App2) and this functor induces a homotopy equivalence in K-theory.

Denote by $\mathcal{MV}'$ the full subcategory of $\mathcal{MV}$ consisting of objects $X \in \mathcal{MV}$ such that $\Phi_1(X)$ belongs to $\mathcal{R}'$. Then an object $X \in \mathcal{MV}$ belongs to $\mathcal{MV}'$ if and only if there is an isomorphism $\Phi_1(X) \simeq VR$ for some $V \in \mathcal{C}$. This category is exact and cofinal in $\mathcal{MV}$. Moreover the functor $\Phi_1$ sends $\mathcal{MV}'$ to $\mathcal{R}'$.

We define the following categories:

- The category $\mathcal{E}_0$ of modules in $\mathcal{R}'$ and isomorphisms
- The category $\mathcal{E}_1$ of objects in $\mathcal{MV}'$ and morphisms inducing isomorphisms under $\Phi_1$
• The category \( \mathcal{E}_2 \) of objects in \( \mathcal{M} \mathcal{V}' \) and epimorphisms inducing isomorphisms under \( \Phi_1 \).

• The category \( \mathcal{E}_3 \) of objects in \( \mathcal{M} \mathcal{V} \times \mathcal{V} \), where a morphism in \( \mathcal{E}_3 \) from \((X, V)\) to \((Y, W)\) is an morphism \( X \oplus V \rightarrow Y \oplus W \) in \( \mathcal{E}_2 \) sending \( X \) to \( Y \).

We have four functors \( f_1 : \mathcal{E}_1 \rightarrow \mathcal{E}_0 \), \( f_2 : \mathcal{E}_2 \rightarrow \mathcal{E}_1 \), \( g_1 : \mathcal{E}_3 \rightarrow \mathcal{E}_1 \) and \( g_2 : \mathcal{E}_3 \rightarrow \mathcal{E}_2 \) where \( f_1 \) is induced by \( \Phi_1 \), \( f_2 \) is the inclusion and \( g_1 \) (resp. \( g_2 \)) is the correspondence \((X, V) \mapsto X \) (resp. \((X, V) \mapsto X \oplus V \)).

In order to prove a connective version of theorems 1, 2 and 3, we'll need to prove that the sequence \( \mathcal{V} \subset \mathcal{M} \mathcal{V}' \rightarrow \mathcal{R}' \) induces a fibration in K-theory and, for that, it will be useful to prove that \( f_1 f_2 \) is a homotopy equivalence.

**2.5 Lemma:** The functor \( f_1 \) is a homotopy equivalence.

**Proof:** It is enough to prove that the fiber category \( f_1/U \) is contractible for each object \( U \in \mathcal{E}_0 = \mathcal{R}' \).

Consider an object \( U \) in \( \mathcal{R}' \) and denote by \( \mathcal{F} \) the fiber category \( f_1/U \). By applying lemma 1.14 with \( X = 0 \) and \( V = U \), we get an object \( Y \in \mathcal{M} \mathcal{V} \) and an isomorphism \( U \cong \Phi_1(Y) \). Hence the category \( \mathcal{F} \) is nonempty.

Consider two objects \((X_1, \varepsilon_1)\) and \((X_2, \varepsilon_2)\) in \( \mathcal{F} \). For \( i = 1, 2 \), \( \varepsilon_i \) is an isomorphism from \( \Phi_1(X_i) \) to \( U \).

By applying lemma 1.14 with \( X = X_1 \oplus X_2 \) and \( f = \varepsilon_1^{-1} \oplus \varepsilon_2^{-1} : U \rightarrow \Phi_1(X) \), we get an object \( Y \in \mathcal{M} \mathcal{V} \), a morphism \( g : Y \rightarrow X_1 \oplus X_2 \) and an isomorphism \( \varepsilon : U \sim \Phi_1(Y) \) such that \( \varepsilon_1^{-1} \oplus \varepsilon_2^{-1} \) is the composite morphism \( U \xrightarrow{\varepsilon} \Phi_1(Y) \xrightarrow{g} \Phi_1(X) \).

Therefore \((Y, \varepsilon_1^{-1})\) is an object in \( \mathcal{F} \) and we have two morphisms \((Y, \varepsilon_1^{-1}) \rightarrow (X_1, \varepsilon_1)\) and \((Y, \varepsilon_1^{-1}) \rightarrow (X_2, \varepsilon_2)\).

Consider two objects \((X_1, \varepsilon_1)\) and \((X_2, \varepsilon_2)\) in \( \mathcal{F} \) and two morphisms \( h_1 \) and \( h_2 \) from \((X_1, \varepsilon_1)\) to \((X_2, \varepsilon_2)\). Denote by \( X \) the kernel of \( h_1 - h_2 \) (in \( \mathcal{F} \)).

For \( i = 1, 2 \), we have an exact sequence:

\[
0 \rightarrow \Phi_1(X_i) \xrightarrow{\mu_i} T\Phi_2(X_i) \xrightarrow{\varphi_i} \Phi_3(X_i)R \rightarrow 0
\]

and then an exact sequence:

\[
0 \rightarrow U \xrightarrow{\mu_i \varepsilon_i^{-1}} T\Phi_2(X_i) \xrightarrow{\varphi_i} \Phi_3(X_i)R \rightarrow 0
\]

So we get for each \( i = 1, 2 \) a commutative diagram with exact lines:

\[
\begin{array}{ccc}
0 & \xrightarrow{} & U \xrightarrow{\mu_1 \varepsilon_1^{-1}} T\Phi_2(X_1) \xrightarrow{\varphi_1} \Phi_3(X_1)R \xrightarrow{} 0 \\
\downarrow & & \downarrow h_i & \downarrow h_i \\
0 & \xrightarrow{} & U \xrightarrow{\mu_2 \varepsilon_2^{-1}} T\Phi_2(X_2) \xrightarrow{\varphi_2} \Phi_3(X_2)R \xrightarrow{} 0
\end{array}
\]
and then an exact sequence:
\[ 0 \rightarrow U \rightarrow T\Phi_2(X) \rightarrow \Phi_3(X)R \]
inducing an isomorphism \( \varepsilon : U \rightarrow \Phi_1(X) \). By applying lemma 1.14 with \( \varepsilon \), we get an object \((Y, u^{-1}) \in \mathcal{F}\) and a morphism \( k : (Y, u^{-1}) \rightarrow (X_1, \varepsilon_1) \) such that: \( h_1k = h_2k \).

Because of these properties, each fiber category \( \mathcal{F} \) is cofiltered and then contractible. Hence the functor \( f_1 \) is a homotopy equivalence. \( \square \)

**2.6 Lemma:** The functor \( g_1 \) is a homotopy equivalence.

**Proof:** Let \( X \) be an object of \( \mathcal{M}' \) and \( \mathcal{F} \) be the fiber category \( g_1/X \). Applying lemma 1.14 to the morphism \( 0 \rightarrow \Phi_1(X) \), we get an object \( E \in \mathcal{M}' \), a morphism \( \alpha : E \rightarrow X \) such that: \( \Phi_1(E) = 0 \) and \( \Phi_2(E) \rightarrow \Phi_2(X) \) and \( \Phi_3(E) \rightarrow \Phi_3(X) \) are epimorphisms. Then \( E \) belongs to \( \mathcal{V} \) and the morphism \( \alpha : E \rightarrow X \) induces epimorphisms on \( \Phi_2 \) and \( \Phi_3 \). Therefore, for each morphism \( f : Y \rightarrow X \) in \( \mathcal{E}_1 \), the morphism \( Y \oplus E \xrightarrow{f \oplus \alpha} X \) belongs to \( \mathcal{E}_2 \).

An object in \( \mathcal{F} \) is a triple \((Y, V, f)\) where \( (Y, V) \) belongs to \( \mathcal{M}' \times \mathcal{V} \) and \( f : Y \rightarrow X \) is a morphism in \( \mathcal{E}_1 \). A morphism \( \varphi : (Y, V, f) \rightarrow (Y', V', f') \) is a morphism \( \varphi : Y \oplus V \rightarrow Y' \oplus V' \) in \( \mathcal{E}_2 \) sending \( Y \) to \( Y' \) such that: \( f = f' \varphi \).

The category \( \mathcal{F} \) is nonempty because it contains the object \((X, 0, \text{Id})\).

We have three functors \( G_0, G_1, G_2 \) from \( \mathcal{F} \) to \( \mathcal{F} \) sending each \((Y, V, f) \in \mathcal{F}\) to \((Y, 0, \text{Id})\), \((Y, V, f) \mapsto G_1(Y, V, f) = (Y, V \oplus E, f)\) and \((Y, 0, \text{Id})\) respectively.

The inclusion \( 0 \subset E \) induces a morphism \( G_0 \rightarrow G_1 \). The morphism \( f \oplus 0 \oplus \alpha : Y \oplus V \oplus E \rightarrow X \) induces a morphism \( (Y, V \oplus E, f) \rightarrow (X, 0, \text{Id}) \) and we get a morphism \( G_1 \rightarrow G_2 \). Therefore the identity of \( \mathcal{F} \) is homotopic to \( G_1 \) and then to \( G_2 \) which is constant. Hence \( \mathcal{F} \) is contractible and, since each fiber category of \( g_1 \) is contractible, \( g_1 \) is a homotopy equivalence. \( \square \)

**2.7 Lemma:** The functor \( g_2 \) is a homotopy equivalence.

**Proof:** Let \( X \) be an object in \( \mathcal{E}_1 \) and \( \mathcal{F} \) be the fiber category \( g_2/X \). An object in \( \mathcal{F} \) is a triple \((Y, V, f)\) where \( (Y, V) \) belongs to \( \mathcal{E}_3 \) and \( f : Y \oplus V \rightarrow X \) is a morphism in \( \mathcal{E}_2 \). A morphism \( \varphi : (Y, V, f) \rightarrow (Y', V', f') \) in \( \mathcal{F} \) is a morphism \( \varphi : Y \oplus V \rightarrow Y' \oplus V' \) in \( \mathcal{E}_2 \) such that \( \varphi(Y) \subset Y' \) and \( f = f' \varphi \). Therefore it is easy to see that, for every \((Y, V, f) \in \mathcal{F}\), we have a unique morphism in \( \mathcal{F} \) from \((Y, V, f)\) to \((X, 0, \text{Id})\). Hence \( \mathcal{F} \) has a final object and is contractible. Since each fiber category of \( g_2 \) is contractible, \( g_2 \) is a homotopy equivalence. \( \square \)

**2.8 Lemma:** The functor \( f_2 \) is a homotopy equivalence.

**Proof:** The inclusion \( X \subset X \oplus V \) for all \((X, V) \in \mathcal{E}_3\) induces a morphism from \( g_1 \) to \( f_2g_2 \) and \( g_1 \) is homotopic to \( f_2g_2 \). But \( g_1 \) and \( g_2 \) are homotopy equivalences. Therefore \( f_2 \) is a homotopy equivalence too. \( \square \)
2.9 Lemma: The following diagram of exact categories:

\[ \mathcal{V} \subset \mathcal{M} \mathcal{V}' \xrightarrow{\Phi_1} \mathcal{R} \]

induces a fibration in K-theory.

Proof: In [Wa1] (lemma 10.2 p. 206), Waldhausen proved that \( Q\mathcal{V} \rightarrow Q.\mathcal{M} \mathcal{V}' \rightarrow Q.\mathcal{F}_R \) is a homotopic fibration in a situation similar to ours. In our situation we’ll prove, essentially in the same way, that the sequence \( Q\mathcal{V} \rightarrow Q.\mathcal{M} \mathcal{V}' \rightarrow Q.\mathcal{R}' \) is a homotopic fibration.

Following Waldhausen’s notations, if \( F \) is an exact subcategory of an exact category \( E \), we have a bicategory \( Q^p(E, F) \) where the horizontal maps form the Quillen’s category \( Q(E) \) and the vertical morphisms form the category of epimorphisms in \( E \) with kernel in \( F \). In particular we have an equivalence between \( Q(E) \) and \( Q^p(F, 0) \) and \( Q(E) \) may be considered as a bicategory.

We have a commutative diagram of bicategories:

\[
\begin{array}{ccc}
Q(\mathcal{V}) & \rightarrow & Q^p(\mathcal{V}, \mathcal{V}) \\
\downarrow & & \downarrow \\
Q(\mathcal{M} \mathcal{V}') & \rightarrow & Q^p(\mathcal{M} \mathcal{V}', \mathcal{V})
\end{array}
\]

which is homotopically cartesian. Moreover \( Q^p(\mathcal{V}, \mathcal{V}) \) is contractible. Therefore the diagram of bicategories:

\[ Q(\mathcal{V}) \rightarrow Q(\mathcal{M} \mathcal{V}') \rightarrow Q^p(\mathcal{M} \mathcal{V}', \mathcal{V}) \]

is a homotopic fibration.

On the other hand the morphism \( f = f_1f_2 : \mathcal{E}_2 \rightarrow \mathcal{R}' \) induces a morphism \( f_* : Q^p(\mathcal{M} \mathcal{V}', \mathcal{V}) \rightarrow Q^p(\mathcal{R}', 0) \) and we want to prove that \( f_* \) is a homotopy equivalence. Actually, the proof of lemma 10.2 in [Wa1] works exactly the same in our situation except maybe for the sublemma (p. 209). In this sublemma, we have a filtered object \( M_1 \subset M_2 \subset \ldots M_{n-1} \subset M_n \) in \( \mathcal{M} \mathcal{V}' \) where each quotient \( M_i/M_{i-1} \) is in \( \mathcal{M} \mathcal{V}' \). Since \( \Phi_1 \) is exact and each module in \( \mathcal{R}' \) is projective, the morphism \( \Phi_1(M_n) \rightarrow \Phi_1(M_n/M_{n-1}) \) is surjective and has a section \( s \) from \( U = \Phi_1(M_n/M_{n-1}) \) to \( \Phi_1(M_n) \).

Because of lemma 1.14, there are an object \( N \in \mathcal{M} \mathcal{V} \), a morphism \( g : N \rightarrow M_n \) inducing epimorphisms on \( \Phi_2 \) and \( \Phi_3 \), and an isomorphism \( U \xrightarrow{\sim} \Phi_1(N) \) making the
Therefore the morphism \( N \rightarrow M_n \) induces epimorphisms on \( \Phi_2 \) and \( \Phi_3 \) and the composite morphism \( N \rightarrow M_n \rightarrow M_n/M_{n-1} \) is an epimorphism with kernel in \( \mathcal{V} \). Hence the sublemma can be proven in our situation and, since \( f \) is a homotopy equivalence, the proof of lemma 10.2 applies completely here. The lemma follows. \( \square \)

2.10 Lemma: Let \( \mathcal{R}'' \) be the full subcategory of \( \mathcal{R} \) generated by the image of \( \Phi_1 : \mathcal{M} \mathcal{V} \rightarrow \mathcal{R} \). Then the diagram:

\[
\begin{array}{ccc}
\mathcal{V} & \xrightarrow{\Phi_1} & \mathcal{R}'' \\
\downarrow & & \downarrow \\
\mathcal{M} \mathcal{V} & \xrightarrow{\Phi_1} & \mathcal{R}''
\end{array}
\]

induces a fibration in \( K \)-theory.

Proof: Let \( X = (E, M, \varphi) \) be an object in \( \mathcal{M} \mathcal{V} \). Since \( E \) is projective in \( \mathcal{D} \), there is a module \( E_1 \in \mathcal{D} \) such that \( E \oplus E_1 \) is free in case 1 or 3 and on the form \( E \oplus E_1 = (F_A, F_B) \in \mathcal{A} \times \mathcal{R} \) with \( F_A \) and \( F_B \) free. Therefore \( T(E \oplus E_1) \) is free in all cases. Let \( X_1 \) be the object \( (E_1, 0, 0) \in \mathcal{M} \mathcal{V} \). We have an exact sequence in \( \mathcal{R} \):

\[
0 \rightarrow \Phi_1(X \oplus X_1) \rightarrow T(E \oplus E_1) \rightarrow MR \rightarrow 0
\]

and \( \Phi_1(X \oplus X_1) \) is stably in \( \mathcal{R}' \). Hence there is another object \( X_2 \in \mathcal{M} \mathcal{V} \) such that \( \Phi_1(X \oplus X_1 \oplus X_2) \) belongs to \( \mathcal{R}' \) and \( \mathcal{M} \mathcal{V}' \) is cofinal in \( \mathcal{M} \mathcal{V} \).

Consider the following commutative diagram:

\[
\begin{array}{ccc}
\mathcal{M} \mathcal{V}' & \xrightarrow{\Phi_1} & \mathcal{R}' \\
\downarrow & & \downarrow \\
\mathcal{M} \mathcal{V} & \xrightarrow{\Phi_1} & \mathcal{R}''
\end{array}
\]

where the vertical maps are the canonical cofinal inclusions.

Let \( K \) be the fiber product of \( K_0(\mathcal{M} \mathcal{V}') \) and \( K_0(\mathcal{R}') \) over \( K_0(\mathcal{R}'') \). The commutativity of the diagram \( K_0(D) \) induce a map \( \lambda : K_0(\mathcal{M} \mathcal{V}') \rightarrow K \). Since the map \( K_0(\mathcal{M} \mathcal{V}') \rightarrow K_0(\mathcal{M} \mathcal{V}) \) is injective (by cofinality) and factorizes through \( K \), the map \( \lambda \) is injective.
Let \( w = (u, v) \) be an element in \( K \). Then we have: \( u \in K_0(\mathcal{M} \mathcal{V}) \), \( v \in K_0(\mathcal{R}') \) and \( \Phi_1(u) \) and \( v \) are the same in \( K_0(\mathcal{R}'') \).

For every object \( X \) in some exact category \( \mathcal{A} \), the class of \( X \) in the Grothendieck group \( K_0(\mathcal{A}) \) will be denoted by \([X]\).

So there are two objects \( X, Y \) in \( \mathcal{M} \mathcal{V} \) such that: \( u = [X] - [Y] \). Since \( \mathcal{M} \mathcal{V}' \) is cofinal in \( \mathcal{M} \mathcal{V} \), there is an object \( Y_1 \) in \( \mathcal{M} \mathcal{V} \) such that \( Y \oplus Y_1 \) is in \( \mathcal{M} \mathcal{V}' \). Let us set: \( w' = w + \lambda[Y \oplus Y_1] \) and \( X' = X \oplus Y_1 \). We have: \( w' = (u', v') \) with \( u' = [X'] \) and \( [\Phi_1(X')] \) belongs to \( K_0(\mathcal{R}') \). Then \( \Phi_1(X') \) is stably isomorphic to a module in \( \mathcal{R}' \). Up to adding to \( X \) (and then to \( X' \)) an object in \( \mathcal{M} \mathcal{V}' \) on the form \((E, 0, 0)\), we may as well suppose that \( \Phi_1(X') \) belongs to \( \mathcal{R}' \) and then that \( X' \) belongs to \( \mathcal{R}' \).

Therefore we have: \( w' - \lambda[X'] = (0, v'') \) where \( v'' \) is an element in \( K_0(\mathcal{R}'') \) killed in \( K_0(\mathcal{R}') \). But the morphism \( K_0(\mathcal{R}') \to K_0(\mathcal{R}'') \) is injective. So we have:

\[
w' - \lambda[X'] = 0 \implies w' = \lambda(X')
\]

and \( w' \) and then \( w \) are in the image of \( \lambda \). Therefore \( \lambda \) is surjective and then bijective.

Consequently the diagram \( K_0(D) \) is exact (cartesian and cocartesian) and, by cofinality, the diagram \( K(D) \) is homotopically cartesian. The lemma follows.

As a consequence we get the following result, which is, in some sense, a connective version of theorems 1, 2 and 3:

**2.11 Proposition:** Let \( X \) be the homotopy fiber of the map \( K(\mathcal{C}_2) \to K(\mathcal{D}) \times F(\mathcal{C}) \) induced by the functor \( F \times \sigma : \mathcal{C}_2 \to \mathcal{D} \times \mathcal{C} \). Then there is a natural homotopy equivalence \( \Omega K(R) \sim \to Nil(\mathcal{C}_2, S) \times X \).

**Proof:** Because of lemma 1.12 the functor \( \Phi : Nil(\mathcal{C}_2, S) \to \mathcal{V} \) is an equivalence of categories and the lemma 2.10 implies that the following diagram:

\[
\begin{array}{ccc}
Nil(\mathcal{C}_2, S) & \xrightarrow{\Phi} & \mathcal{M} \mathcal{V} \xrightarrow{\Phi_1} \mathcal{R}' \\
\downarrow & & \downarrow \\
Nil(\mathcal{C}_2, S) & \xrightarrow{\Phi'} & \mathcal{D} \times \mathcal{C}
\end{array}
\]

induces a fibration in K-theory. Hence \( \Omega K(\mathcal{R}') \simeq \Omega K(R) \) is homotopically equivalent to the homotopy fiber of the map induced by \( \Phi : Nil(\mathcal{C}_2, S) \to \mathcal{M} \mathcal{V} \) in K-theory.

Because of lemma 2.4, we have a commutative diagram

\[
\begin{array}{ccc}
Nil(\mathcal{C}_2, S) & \xrightarrow{\Phi} & \mathcal{M} \mathcal{V} \\
\downarrow & & \downarrow \\
Nil(\mathcal{C}_2, S) & \xrightarrow{\Phi'} & \mathcal{D} \times \mathcal{C}
\end{array}
\]

where the functor \( \Phi_2 \times \Phi_3 \) induces a homotopy equivalence in K-theory. Therefore \( \Omega K(R) \) is homotopically equivalent to the homotopy fiber of the map \( \Phi' : K(Nil(\mathcal{C}_2, S)) \to K(\mathcal{D} \times \mathcal{C}) \).
The functor $\Phi'$ sends an object $(H, \theta) \in \mathcal{Nil}(C_2, S)$ to the pair $(F(H), \sigma(H)) \in \mathcal{D} \times \mathcal{C}$ and $\Phi'$ factorizes by the forgetful map $\mathcal{Nil}(C_2, S) \rightarrow \mathcal{C}_2$. Therefore $\Omega K(R)$ is homotopically equivalent to the homotopy fiber of $\Phi' : K(C_2) \times \mathcal{Nil}(C_2, S) \rightarrow K(\mathcal{D}) \times K(\mathcal{C})$ where $\Phi'$ is trivial on $\mathcal{Nil}(C_2, S)$ and induced by the functor $F \times \sigma$ on $K(\mathcal{C}_2)$. The lemma follows.

2.12 The spectra $K$ and $\mathcal{Nil}$.

The K-theory of Quillen is a functor $K$ from the category of rings to the category of infinite loop spaces. There are different methods to construct a so called negative $K$-theory: that is a functor $K'$ from the category of rings to the category $\Omega$sp of $\Omega$-spectra (see [B] and [KV]) and a natural homotopy equivalence from $K(A)$ to the 0-th term of $K'(A)$ such that the following sequence is exact for every ring $A$ and every integer $i \in \mathbb{Z}$:

$$0 \rightarrow K_i(A) \rightarrow K_i(A[t]) \oplus K_i(A[t^{-1}]) \rightarrow K_i(A[t, t^{-1}]) \rightarrow K_{i-1}(A) \rightarrow 0$$

where $K_i(A)$ is the $i$-th homotopy group of $K'(A)$. This exact sequence was proven by Bass [B] for $i = 1$ and generalized by Quillen for $i > 0$ [Q]. The morphisms of this exact sequence are induced by the inclusions $A \subset A[t] \subset A[t, t^{-1}]$, $A \subset A[t^{-1}] \subset A[t, t^{-1}]$ except for the map $\partial : K_i(A[t, t^{-1}]) \rightarrow K_{i-1}(A)$. But this map $\partial$ has a section induced by the multiplication by $t \in K_1(\mathbb{Z}[t, t^{-1}])$. Therefore the exact sequence above is natural in $A$.

Inspired by the Karoubi-Villamayor method [KV], we'll define our version $\overline{K}(A)$ of negative K-theory as follows:

Denote by $E$ the set of infinite square matrices with entries in $\mathbb{Z}$ having only finitely many nonzero entries in each row and each column. This ring has a two-sided ideal $M(\mathbb{Z})$ of matrices having only finitely many nonzero entries. So we set: $\Sigma = E/M(\mathbb{Z})$.

For every ring $A$, $EA = E \otimes_{\mathbb{Z}} A$ and $\Sigma A = \Sigma \otimes_{\mathbb{Z}} A$ are rings and the morphism $f : EA \rightarrow \Sigma A$ is a surjective ring homomorphism. It is easy to see that the kernel of $f$ is isomorphism, as a pseudo ring, to $M(A)$ and that $EA$ is a flasque ring. Therefore (see [KV]) we have a natural homotopy equivalence:

$$K(A) \sim \Omega K(\Sigma A)$$

and the sequence $K(\Sigma^n A)$ is an $\Omega$-spectrum. This spectrum will be denoted by $\overline{K}(A)$ and $\overline{K}$ is a negative K-theory. For each integer $i \in \mathbb{Z}$ we set also: $K_i(A) = \pi_i(\overline{K}(A))$.

2.13 Lemma: Let $(A, S)$ be a left-flat bimodule. Then for each integer $n \geq 0$, $(\Sigma^n A, \Sigma^n S)$ is a left-flat bimodule and the sequence $\mathcal{Nil}(\Sigma^n A, \Sigma^n S)$ is an $\Omega$-spectrum denoted by $\overline{\mathcal{Nil}}(A, S)$. Moreover we have a natural homotopy equivalence from $\mathcal{Nil}(A, S)$ to the 0-th term of $\overline{\mathcal{Nil}}(A, S)$ and, for each integer $i \in \mathbb{Z}$, we have an exact sequence which is natural on the left-flat bimodule $(A, S)$ :

$$0 \rightarrow \mathcal{Nil}_i(A, S) \rightarrow \mathcal{Nil}_i(A[t], S[t]) \oplus \mathcal{Nil}(A[t^{-1}], S[t^{-1}]) \rightarrow$$
\[ \text{Nil}_i(A[t, t^{-1}], S[t, t^{-1}]) \longrightarrow \text{Nil}_{i-1}(A, S) \longrightarrow 0 \]

where \( \text{Nil}_i(?) \) is the \( i \)-th homotopy group of \( \text{Nil}(?) \).

**Proof:** Let \((A, S)\) be a left-flat bimodule. For every ring \(B\), \(BS = B \otimes_Z S\) is a \(BA\)-bimodule. Since \(S\) is flat on the left \(S\), as a left \(A\)-module, is isomorphic to a filtered colimit of free left \(A\)-modules \(E_i\) and \(BS\) is also isomorphic to a filtered colimit of free \(BA\)-modules \(BE_i\). Therefore \(BS\) is flat on the left and \((BA, BS)\) is a left-flat bimodule. In particular each \((\Sigma^n A, \Sigma^n S)\) is a left-flat bimodule. Moreover we have a natural isomorphism of rings: \( \Sigma(A[S]) \simeq (\Sigma A)[\Sigma S] \).

Consider the case 1 (with \(C = A\)). Because of proposition 2.11, we have a natural homotopy equivalence:

\[ \Omega K(A[S]) \sim \text{Nil}(A, S) \times X \]

where \(X\) is the homotopy fiber of the map: \( K(\mathcal{C}_2) \xrightarrow{F \times \sigma} K(\mathcal{D} \times \mathcal{C})\). But in case 1, \(\mathcal{C}_2\), \(\mathcal{D}\) and \(\mathcal{C}\) are equal to the category \(\mathcal{A}\) of finitely generated projective right \(A\)-modules and functors \(F\) and \(\sigma\) are the identity. Therefore \(X\) is nothing else but the loop space of \(K(A)\). So we get a natural homotopy equivalence:

\[ \Omega K(A[S]) \sim \text{Nil}(A, S) \times \Omega K(A) \]

By naturality, we get a homotopy equivalence from \(\text{Nil}(A, S)\) to the homotopy fiber of the map \(\Omega K(A[S]) \longrightarrow \Omega K(A)\) induced by the canonical ring homomorphism \(A[S] \longrightarrow A\).

We have a commutative diagram:

\[
\begin{array}{ccc}
K(A[S]) & \longrightarrow & K(A) \\
\sim \downarrow & & \sim \downarrow \\
\Omega K(\Sigma(A[S])) & \longrightarrow & \Omega K(\Sigma A)
\end{array}
\]

where the horizontal maps are induced by the canonical morphism \(A[S] \longrightarrow A\) and the vertical maps are homotopy equivalences.

But \(\Sigma(A[S])\) is isomorphic to \((\Sigma A)[\Sigma S]\). So we get a commutative diagram:

\[
\begin{array}{ccc}
\Omega K(A[S]) & \longrightarrow & \Omega K(A) \\
\sim \downarrow & & \sim \downarrow \\
\Omega^2 K((\Sigma A)[\Sigma S]) & \longrightarrow & \Omega^2 K(\Sigma A)
\end{array}
\]

36
inducing a homotopy equivalence \( \text{Nil}(A, S) \sim \Omega \text{Nil}(\Sigma A, \Sigma S) \). Then the sequence of spaces \( \text{Nil}(\Sigma^n A, \Sigma^n S) \) is a well defined \( \Omega \)-spectrum \( \overline{\text{Nil}}(A, S) \) and we have a natural decomposition:

\[
\Omega K(A[S]) \sim \overline{\text{Nil}}(A, S) \times \Omega K(A)
\]

Let us set: \( \text{Nil}_i(A, S) = \pi_i(\overline{\text{Nil}}(A, S)) \). Then we have, for every left-flat bimodule \((A, S)\) and every integer \(i \in \mathbb{Z}\) an isomorphism \( K_i(A[S]) \simeq \text{Nil}_{i-1}(A, S) \oplus K_i(A) \).

For the ring \( A \) we have, for every integer \( i \in \mathbb{Z} \), the following exact sequence \( S_i(A) \):

\[
0 \rightarrow K_i(A) \rightarrow K_i(A[t]) \oplus K_i(A[t^{-1}]) \rightarrow K_i(A[t, t^{-1}]) \rightarrow K_{i-1}(A) \rightarrow 0
\]

For \( B = \mathbb{Z}[t] \) or \( B = \mathbb{Z}[t^{-1}] \) or \( B = \mathbb{Z}[t, t^{-1}] \), the ring \( B(A[S]) \) is isomorphic to \((BA)[BS]\). Then the sequence \( S_{i+1}(A[S]) \) decomposes into \( S_{i+1}(A) \) and the following sequence:

\[
0 \rightarrow \text{Nil}_i(A, S) \rightarrow \text{Nil}_i(A[t], S[t]) \oplus \text{Nil}_i(A[t^{-1}], S[t^{-1}]) \rightarrow \text{Nil}_i(A[t, t^{-1}], S[t, t^{-1}]) \rightarrow \text{Nil}_{i-1}(A, S) \rightarrow 0
\]

which, as a consequence, is exact.

\(\square\)

2.14 Proofs of theorems 1, 2 and 3.

In the proof of lemma 2.13, we have constructed the \( \Omega \)-spectrum \( \overline{\text{Nil}}(?) \) and the first two properties of theorem 1 have already been proven.

Suppose \( A \) is regular coherent on the right, i.e. every finitely presented right \( A \)-module has a finite resolution by finitely generated projective modules. The category \( \mathcal{A} \) of finitely presented projective right \( A \)-modules is contained in the category \( \mathcal{A}' \) of finitely presented right \( A \)-modules. The category \( \mathcal{N} \text{il}(A, S) \) is also contained in the category \( \mathcal{N} \text{il}'(A, S) \) of pairs \((H, \theta)\) with \( H \in \mathcal{A}' \) and \( \theta : H \rightarrow HS \) nilpotent. Moreover \( \mathcal{A} \) is stable in \( \mathcal{A}' \) under extension and kernel of admissible epimorphism and the inclusion \( \mathcal{N} \text{il}(A, S) \subset \mathcal{N} \text{il}'(A, S) \) have the same properties. Therefore, by the resolution theorem [Q], the inclusions \( \mathcal{A} \subset \mathcal{A}' \) and \( \mathcal{N} \text{il}(A, S) \subset \mathcal{N} \text{il}'(A, S) \) induce homotopy equivalences in K-theory.

On the other hand, we have an inclusion \( \mathcal{A}' \rightarrow \mathcal{N} \text{il}'(A, S) \) sending \( H \) to the pair \((H, 0)\) and every object \((H, \theta)\) in \( \mathcal{N} \text{il}'(A, S) \) has a finite filtration with subquotients in \( \mathcal{A}' \). Moreover \( \mathcal{A}' \) and \( \mathcal{N} \text{il}'(A, S) \) are abelian categories and \( \mathcal{A}' \) is closed in \( \mathcal{N} \text{il}'(A, S) \) under subobjects and quotients. Therefore, by the devissage theorem [Q], the inclusion \( \mathcal{A}' \subset \mathcal{N} \text{il}'(A, S) \) induces a homotopy equivalence in K-theory. As a consequence the inclusion \( \mathcal{A} \subset \mathcal{N} \text{il}(A, S) \) induce a homotopy equivalence in K-theory and the space \( \text{Nil}(A, S) \) is contractible.

Hence for every left-flat bimodule \((A, S)\), with \( A \) regular coherent, the space \( \text{Nil}(A, S) \) is contractible. and \( \text{Nil}_i(A, S) \) is trivial for every \( i \geq 0 \).

Consider the following property \( E(n) \) where \( n \) is any integer:
• For every left-flat bimodule \((A, S)\) with \(A\) regular coherent on the right, the module \(\text{Nil}_i(A, S)\) is trivial for every \(i \geq n\).

The property \(E(0)\) is then satisfied. Suppose \(E(n)\) is true and take a left-flat bimodule \((A, S)\) with \(A\) regular coherent on the right. Then \(A[t], A[t^{-1}]\) and \(A[t, t^{-1}]\) are also regular coherent on the right and, in the exact sequence:

\[
0 \rightarrow \text{Nil}_n(A, S) \rightarrow \text{Nil}_n(A[t], S[t]) \oplus \text{Nil}_n(A[t^{-1}], S[t^{-1}]) \rightarrow \\
\text{Nil}_n(A[t, t^{-1}], S[t, t^{-1}]) \rightarrow \text{Nil}_{n-1}(A, S) \rightarrow 0
\]

all the modules are zero except \(\text{Nil}_{n-1}(A, S)\). Hence the module \(\text{Nil}_{n-1}(A, S)\) is also trivial and the property \(E(n-1)\) is true.

By induction \(E(n)\) is satisfied for all \(n\). Hence \(\text{Nil}(A, S)\) is contractible for every left-flat bimodule \((A, S)\) with \(A\) regular coherent on the right and theorem 1 is proven.

Consider the case 2. The ring \(R\) is defined by the cocartesian diagram:

\[
\begin{array}{ccc}
C & \xrightarrow{\alpha} & A \\
\beta \downarrow & & \downarrow \\
B & \xrightarrow{} & R
\end{array}
\]

\((D)\)

By tensoring by \(\Sigma^n\), we get a cocartesian diagram:

\[
\begin{array}{ccc}
\Sigma^nC & \xrightarrow{\alpha} & \Sigma^nA \\
\beta \downarrow & & \downarrow \\
\Sigma^nB & \xrightarrow{} & \Sigma^nR
\end{array}
\]

\((\Sigma^nD)\)

We remark that the morphism \(\alpha : \Sigma^nC \rightarrow \Sigma^nA\) (resp. \(\beta : \Sigma^nC \rightarrow \Sigma^nB\)) is pure with complement \(\Sigma^nA'\) (resp. \(\Sigma^nB'\)). Therefore in this new situation, we get new rings: \(\Sigma^nC, \Sigma^nA, \Sigma^nB, \Sigma^nR, \Sigma^nC \times \Sigma^nC\) and a new bimodule \(\Sigma^nS\).

Because of proposition 2.11, we have a homotopy equivalence between \(\Omega K(\Sigma^nR)\) and \(\text{Nil}(\Sigma^nC \times \Sigma^nC, \Sigma^nS) \times X_n\) where \(X_n\) is the homotopy fiber of \(f : K(\Sigma^nC \times \Sigma^nC) \rightarrow K(\Sigma^nA) \times K(\Sigma^nB) \times K(\Sigma^nC)\).

The morphism \(f\) is induced by the functor \(\mathcal{C} \times \mathcal{C} \rightarrow \mathcal{A} \times \mathcal{B} \times \mathcal{C}\) sending \((M, M') \in \mathcal{C} \times \mathcal{C}\) to \((MA, M'B, M \oplus M')\). Denote by \(f_n(\alpha)\) (resp. \(f_n(\beta)\)) the map \(K(\Sigma^nC) \rightarrow K(\Sigma^nA)\) (resp. \(K(\Sigma^nC) \rightarrow K(\Sigma^nB)\)) induced by \(\alpha\) (resp. \(\beta\)). Then \(X_n\) is homotopy equivalent to the homotopy fiber of \(f_n(\alpha) - f_n(\beta) : K(\Sigma^nC) \rightarrow \)
By naturality of the homotopy equivalence: $K(?) \simeq \Omega K(?)$, we get a homotopy equivalence $X_n \rightarrow \Omega X_{n+1}$ and the sequence of $X_n$ defines an $\Omega$-spectrum $X$ together with a homotopy cartesian diagram of spectra:

$$
\begin{array}{ccc}
K(C) & \longrightarrow & K(A) \\
\downarrow & & \downarrow \\
K(B) & \longrightarrow & \Omega^{-1}X
\end{array}
$$

and that finishes the proof of theorem 2.

Consider now the case 3. We proceed as before and we get a homotopy equivalence between $\Omega K(\Sigma^nR)$ and $\text{Nil}(\Sigma^nC \times \Sigma^nC, \Sigma^nS) \times X_n$ where $X_n$ is the homotopy fiber of the map $f : K(\Sigma^nC \times \Sigma^nC) \rightarrow K(\Sigma^nA) \times K(\Sigma^nC)$ induced by the functor $F \times \sigma : \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{A} \times \mathcal{C}$ sending $(M, M') \in \mathcal{C} \times \mathcal{C}$ to $(M_A \oplus M'_{\beta A}, M \oplus M')$.

Denote by $f_n(\alpha)$ (resp. $f_n(\beta)$) the map $K(\Sigma^nC) \rightarrow K(\Sigma^nA)$ induced by $\alpha$ (resp. $\beta$). Then $X_n$ is homotopy equivalent to the homotopy fiber of $f_n(\alpha) - f_n(\beta)$.

As before, we get a homotopy equivalence $X_n \rightarrow \Omega X_{n+1}$ and the sequence of $X_n$ defines an $\Omega$-spectrum $X$ which is the homotopy fiber of the map $f(\alpha) - f(\beta) : K(C) \rightarrow K(A)$. Therefore we have a homotopy fibration of spectra:

$$
\begin{array}{ccc}
K(C) & \overset{f(\alpha) - f(\beta)}{\longrightarrow} & K(A) \\
& & \Omega^{-1}X
\end{array}
$$

and that finishes the proof of theorem 3.

\[ \square \]

3. Properties of the functor $\text{Nil}$.

Consider two rings $A$ and $B$. Every right $A \times B$-module $M$ is determined by two right modules $M_a$ and $M_b$, where $M_a$ is an $A$-module and $M_b$ is a $B$-module. By setting: $R_a = A$ and $R_b = B$, we see that $M_i$ is a right $R_i$-module for each $i \in \{a, b\}$.
If $E$ is an $A \times B$-bimodule, $E$ is determined by four bimodules $aE_a$, $aE_b$, $bE_a$ and $bE_b$, and for each $i, j$ in $\{a, b\}$, $iE_j$ is a $(R_i, R_j)$-bimodule.

Suppose $f : M \rightarrow ME$ is a morphism of right $A \times B$-modules. Then $f$ is determined by four morphisms $i_f j : M_j \rightarrow M_i iE_j$ and $i_f j$ is a morphism of right $R_j$-modules.

3.1 Lemma: Let $A$ and $B$ be two rings and $E$ be an $A \times B$-bimodule. Suppose $E$ is flat on the left. Then the correspondences

$$(M, f) \mapsto (M_b, b f_b)$$

$$(M, f) \mapsto (M_a, a f_a + \sum_{k \geq 0} a f_b(b f_b)^k b f_a)$$

induce two well defined functors:

$$\Phi_1 : \mathcal{N}il(A \times B, E) \rightarrow \mathcal{N}il(B, b E_b)$$

$$\Phi_2 : \mathcal{N}il(A \times B, E) \rightarrow \mathcal{N}il(A, a E_a \oplus \bigoplus_{k \geq 0} a E_b(b E_b)^k b E_a)$$

Moreover, if $E_b$ is flat on the right, these functors induce a homotopy equivalence of spectra:

$$\mathcal{N}il(A \times B, E) \sim \mathcal{N}il(B, b E_b) \times \mathcal{N}il(A, a E_a \oplus \bigoplus_{k \geq 0} a E_b(b E_b)^k b E_a)$$

This lemma will be proven in 3.7.

Using this result, we are able to prove theorem 4. Consider two rings $A$ and $B$, an $(A, B)$-bimodule $S$ and a $(B, A)$-bimodule $T$. Suppose $S$ and $T$ are flat on both sides. Define the $A \times B$-bimodule $E$ by:

$$aE_b = S \quad bE_a = T \quad aE_a = bE_b = 0$$

Actually, this bimodule is the bimodule $S \oplus T$, where $S$ and $T$ are considered as $A \times B$-bimodules (via the projections $A \times B \rightarrow A$ and $A \times B \rightarrow B$). Moreover $E = S \oplus T$ is flat on both sides.

Applying lemma 3.1, we get two functors:

$$\Phi_1 : \mathcal{N}il(A \times B, E) \rightarrow \mathcal{N}il(B, 0)$$

$$\Phi_2 : \mathcal{N}il(A \times B, E) \rightarrow \mathcal{N}il(A, ST)$$

and a homotopy equivalence of spectra:

$$\Phi(S, T) : \mathcal{N}il(A \times B, E) \sim \mathcal{N}il(A, ST)$$

By exchanging the roles of $A$ and $B$, and $S$ and $T$ we get also a homotopy equivalence of spectra:

$$\Phi(T, S) = \mathcal{N}il(A \times B, E) \sim \mathcal{N}il(B, TS)$$

$\square$
3.2 Proof of theorem 5.

Let $A$ be a ring, $I$ be a set and $S_i$, $i \in I$ be a family of $A$-bimodules flat on both sides. The direct sum of the $S_i$’s will be denoted by $S$.

Let $(M, f)$ be an object of the category $\mathcal{Nil}(A, S)$. The morphism $f : M \rightarrow MS$ decomposes into a finite sum: $f = \sum_{i \in I} f_i$, where $f_i$ is a morphism from $M$ to $MS_i$.

If $u = i_1i_2 \ldots i_p$ is a word in $W(I)$, we set:

$$f_u = f_{i_1}f_{i_2} \ldots f_{i_p} \quad \text{and} \quad S_u = S_{i_1}S_{i_2} \ldots S_{i_p}$$

If $J$ is a subset of $W(I)$, we set also:

$$f_J = \sum_{u \in J} f_u \quad \text{and} \quad S_J = \bigoplus_{u \in J} S_u$$

We check that $f_u$ is a morphism from $M$ to $MS_u$ and $f_J$ is a morphism from $M$ to $MS_J$.

Let $u$ be a non empty word in $W(I)$. Then the correspondence $(M, f) \mapsto (M, f_u)$ induces an exact functor $\varphi_u : \mathcal{Nil}(A, S) \rightarrow \mathcal{Nil}(A, S_u)$. If $J$ is a subset of $W(I)$ that does not contains the empty word, the correspondence $(M, f) \mapsto (M, f_J)$ induces also an exact functor $\varphi_J : \mathcal{Nil}(A, S) \rightarrow \mathcal{Nil}(A, S_J)$. These functors are compatible with tensor product with any power of $\Sigma$ and induce morphisms of spectra on K-theory.

Consider two words $u$ and $v$ in $W(I)$. We have four $A$-bimodules: $S_u$, $S_v$, $S_{uv}$ and $S_{vu}$. Using notations in 1.4, for each $A$-bimodule $T$ and each $(i, j) \in \{1, 2\}^2$ we get an $A \times A$-bimodule $^iT^j$ where $A \times A$ acts on the left of $T$ via the $i$-th projection and on the right via the $j$-th projection. We have a commutative diagram of exact categories:

$$
\begin{array}{cccc}
\mathcal{Nil}(A, S) & \xrightarrow{F} & \mathcal{Nil}(A \times A, ^1S_u^2 \oplus ^2S_v^1) & \xrightarrow{\psi(u,v)} & \mathcal{Nil}(A, S_{uv}) \\
\gamma & & \downarrow G & & \sim \\
\mathcal{Nil}(A, S) & \xrightarrow{F'} & \mathcal{Nil}(A \times A, ^2S_u^1 \oplus ^1S_v^2) & \xrightarrow{\psi(v,u)} & \mathcal{Nil}(A, S_{vu})
\end{array}
$$

where $F$ and $F'$ are defined by:

$$F(M, f) = (M^1 \oplus M^2, f_u + f_v) \quad \quad F'(M, f) = (M^1 \oplus M^2, f_v + f_u)$$

for each $(M, f) \in \mathcal{Nil}(A, S)$ and the morphisms $G$, $\psi(u, v)$ and $\psi(v, u)$ are defined by sending each $(M, M', f + f')$ (with $M, M' \in \mathcal{A}$, $f : M \rightarrow M'S_v$ and $f' : M' \rightarrow MS_u$) to

$$G(M, M', f + f') = (M', M, f + f') \quad \psi(u, v)(M, M', f + f') = (M, f'f)$$
\[ \psi(v, u)(M, M', f + f') = (M', ff') \]

Because of theorem 4, this diagram induces a homotopy commutative diagram of \( \Omega \)-spectra:

\[
\begin{array}{ccc}
\text{Nil}(A, S) & \xrightarrow{F} & \text{Nil}(A \times A, 1S_u^2 \oplus 2S_v^1) \\
\downarrow & & \downarrow \sim \\
\text{Nil}(A, S) & \xrightarrow{F'} & \text{Nil}(A \times A, 2S_u^1 \oplus 1S_v^2) \\
\end{array}
\]

\[
\psi(u, v) \\
\sim \\
\psi(v, u)
\]

where \( \psi(u, v) \) and \( \psi(v, u) \) are homotopy equivalences and \( H \) is the map \( \psi(u, v)^{-1}G \psi(v, u) \) (up to homotopy).

On the other hand we have: \( \psi(u, v)F = \varphi_{uv} \) and \( \psi(v, u)F' = \varphi_{vu} \). Then we have a homotopy commutative diagram:

\[
\begin{array}{ccc}
\text{Nil}(A, S) & \xrightarrow{\varphi_{uv}} & \text{Nil}(A, S_{uv}) \\
\downarrow & & \downarrow \sim \\
\text{Nil}(A, S) & \xrightarrow{\varphi_{vu}} & \text{Nil}(A, S_{vu}) \\
\end{array}
\]

and the homotopy class of the map \( \varphi_u \) depends only on the class of \( u \) in \( CW(I) \). Therefore, to prove the theorem, its is enough to prove it for some admissible set \( X \).

3.3 Lemma: Suppose \( I \) has exactly two elements \( i \) and \( j \). Let \( J \subset W(I) \) be the set of elements \( i^k j \), for \( k \geq 0 \). Then the functors: \( \varphi_i : \text{Nil}(A, S) \to \text{Nil}(A, S_i) \) and \( \varphi_J : \text{Nil}(A, S) \to \text{Nil}(A, S_J) \) induce a homotopy equivalence of spectra:

\[ \text{Nil}(A, S) \xrightarrow{\sim} \text{Nil}(A, S_i) \times \text{Nil}(A, S_J) \]

Proof: We apply lemma 3.1 in the following case:

\[
\begin{align*}
B &= A \\
\_aE_a &= S_i & \_bE_b &= 0 & \_bE_a &= A & \_aE_b &= S_j
\end{align*}
\]

and we get a homotopy equivalence of spectra:

\[ \text{Nil}(A \times A, E) \xrightarrow{\sim} \text{Nil}(A, S_i \oplus S_j) = \text{Nil}(A, S) \]

induced by the functor \((P, Q, f) \mapsto (P, \_aE_a + \_bE_b, \_bE_a)\).
By exchanging the role of \( a \) and \( b \), we have also a homotopy equivalence of spectra:

\[
\underline{Nil}(A \times A, E) \sim \underline{Nil}(A, S_i) \times \left( \bigoplus_{k \geq 0} S_k^i S_j \right) = \underline{Nil}(A, S_i) \times \underline{Nil}(A, S_j)
\]

and this map is induced by the two functors:

\[
(P, Q, f) \mapsto (P, a f_a)
\]

\[
(P, Q, f) \mapsto (Q, \sum_{k \geq 0} b f_a (a f_a)^k a f_b)
\]

Because of theorem 4, this last functor is, after applying the functor \( \underline{Nil} \), equivalent to the functor:

\[
(P, Q, f) \mapsto (P, \sum_{k \geq 0} (a f_a)^k a f_b b f_a)
\]

Therefore we get a homotopy equivalence of spectra:

\[
\underline{Nil}(A, S) \sim \underline{Nil}(A, S_i) \times \underline{Nil}(A, S_j)
\]

induced by the two functors:

\[
(P, f) \mapsto (P, f_i)
\]

\[
(P, f) \mapsto (P, \sum_{k \geq 0} f_i^k f_j)
\]

and the lemma follows. \( \square \)

From now one, the coproduct in the category of spectra will be denoted by \( \bigoplus \) and the trivial spectrum will be denoted by \( 0 \). Actually, is \( E_j \) is a family of spectra, the spectrum \( \bigoplus_j E_j \) is nothing else but the filtered colimit of finite products of the \( E_j \)'s.

Let \( X \) be an admissible set in \( W(I) \). Then the map: \( X \subset W(I) \xrightarrow{\pi} CW(I) \)

induces a bijection \( X \sim \rightarrow CW_0(I) \).

For every object \( (M, f) \in \mathcal{Nil}(A, S) \) there are only finitely many non zero morphisms \( f_u \) and the product of the \( \varphi_u \), for \( u \in X \), induces a map:

\[
\underline{Nil}(A, S) \rightarrow \prod_{u \in X} \underline{Nil}(A, S_u)
\]

with values in \( \bigoplus_{u \in X} \underline{Nil}(A, S_u) \). Hence we have a morphism of spectra:

\[
F : \underline{Nil}(A, S) \rightarrow \bigoplus_{u \in X} \underline{Nil}(A, S_u)
\]

and the last thing to do is to prove that \( F \) is a homotopy equivalence.
On the other hand, we have a homotopy commutative diagram:

\[
\begin{array}{ccc}
\lim_{\rightarrow} \text{Nil}(A, \oplus_{j \in J} S_j) & \longrightarrow & \lim_{\rightarrow} \left( \bigoplus_{u \in X \cap W(I)} \text{Nil}(A, S_u) \right) \\
\sim & \Downarrow & \sim \\
\text{Nil}(A, S) & \longrightarrow & \bigoplus_{u \in X} \text{Nil}(A, S_u)
\end{array}
\]

where the limit is taken over all finite subset \( J \) of \( I \). Moreover vertical arrows of this diagram are homotopy equivalences and, in order to prove the theorem, it is enough to consider the case where \( I \) is finite.

If \( I \) has at most 1 elements there is nothing to prove. So we may suppose that \( I \) is a finite set with at least 2 elements.

If \( J \) is a subset of \( W(I) \) and \( j \) an element of \( J \), we denote by \( Z(J,j) \) the set of words in \( W(I) \) on the form \( j^p j' \), where \( j' \) is any element in \( J \) distinct from \( j \) and \( p \) is any non negative integer.

3.4 Lemma: Suppose \( I \) is finite with at least 2 elements. Then there exists a sequence \((J_n, j_n)\), for \( n \geq 0 \), with the following properties:

- for every integer \( n \geq 0 \), \( J_n \) is a subset of \( W(I) \), \( j_n \) is an element of \( J_n \) and \( J_{n+1} \) is the set \( Z(J_n, j_n) \)
- the set \( Y = \{j_0, j_1, j_2, j_3, \ldots\} \subset W(I) \) is admissible
- for every integer \( p > 0 \), there is an integer \( m \geq 0 \) such that:
  \[
  \forall n > m, \ \forall u \in J_n, |u| > p
  \]

where \( |u| \) is the length of \( u \).

Proof: In order to define the sequence \((J_n, j_n)\), it’s enough to define \( J_0 \) and to choose each \( j_n \) in \( J_n \). So we set: \( J_0 = I \) and, for each \( n, j_n \) is chosen to be an element of \( J_n \) of minimal length in \( W(I) \).

Let \( n \geq 0 \) be an integer. Set: \( J = J_n, j = j_n \) and denote by \( J' \) the complement of \( j \) in \( J \). The inclusion \( J_{n+1} = Z(J, j) \subset W(I) \) factorizes through \( W(J) \) and \( J_{n+1} \) can be considered as a subset of \( W(J) \). Every word \( u \) in \( W(J) \) is written uniquely in the following form:

\[
u = j_0 j_1 j_2 j_3 \cdots j_p j_p^n\]

with: \( p \geq 0, n_s \geq 0, j_s \in J' \).

Suppose \( u \) is reduced.

If \( p = 0 \), then \( u \) is a power of \( j \) and, because \( u \) is reduced, we have: \( u = j \).

If \( p > 0 \), then \( u \) is, up to conjugation, on the form:

\[
u = j_0 j_1 j_2 \cdots j_p j_p^{n_p - 1} j_p\]
and \( u \) is conjugate to an element in \( W_0(Z(J,j)) = W_0(J_{n+1}) \). Moreover \( u \) is reduced in \( W(J) \) if and only is \( u \) is reduced in \( W(I) \).

Therefore every element in \( CW_0(J) = CW_0(J_n) \) belongs to the image of the map \( CW(J_{n+1}) \rightarrow CW(J_n) \) except the element \( j = j_n \) and the inclusion \( J_{n+1} \subset J_n \) induces a bijection \( \{ j_n \} \prod CW_0(J_{n+1}) \simto CW_0(J_n) \). As a consequence, we have, for each \( n \geq 0 \), a bijection:

\[
\{ j_0, j_1, \ldots, j_{n-1} \} \prod CW_0(J_n) \simto CW_0(I)
\]

For each integer \( n \geq 0 \), denote by \( p_n \) the minimal length of the words in \( J_n \). Since \( J_{n+1} \) is contained in \( W(J_n) \), we have: \( p_{n+1} \geq p_n \) and the sequence \( (p_n) \) is increasing. We’ll prove that this sequence is unbounded.

Let \( n \geq 0 \) be an integer. For every \( u \in J_n \), we have: \( |u| \geq p_n \). For every integer \( m \), denote by \( H_m \) the set of elements \( u \in J_m \) with \( |u| = p_n \) and by \( CH_m \) its image in \( CW(I) \). Since \( I \) is finite and every element of \( H_m \) is reduced in \( W(J_m) \), \( CH_m \) is a finite set contained in \( CW_0(I) \).

Denote by \( q \) the cardinal of \( CH_n \). Since \( j_n \) is an element in \( J_n \) of minimal length \( j_n \) belongs to \( H_n \). Then we have: \( q > 0 \) and, because of the the bijection \( \{ j_n \} \prod CW_0(J_{n+1}) \simto CW_0(J_n) \), the cardinal of \( CH_{n+1} \) is \( q - 1 \). For the same reason, we have the following:

\[
\forall i \in \{ 0, 1, \ldots, q \}, \quad \text{card}(CH_{n+i}) = q - i
\]

and then:

\[
\text{card}(CH_{n+q}) = 0 \quad \text{and} \quad p_{n+q} > p_n
\]

Therefore the sequence \( (p_n) \) is unbounded and the last property of the lemma is proven.

Since the map \( \{ j_0, j_1, \ldots, j_{n-1} \} \prod CW_0(J_n) \simto CW_0(I) \) is bijective, the map \( f : Y \rightarrow CW_0(I) \) is injective. Let \( u \) be an element in \( CW_0(I) \) with length \( p \). Since the sequence \( p_n \) is unbounded, there is an integer \( n \) such that \( p_n > p \) and \( u \) doesn’t belong to the image of \( CW_0(J_n) \rightarrow CW_0(I) \). Hence \( u \) belongs to the image of \( \{ j_0, j_1, \ldots, j_{n-1} \} \rightarrow CW_0(I) \) and \( f \) is surjective. Therefore \( Y \) is admissible and the lemma is proven.

For every \( n > 0 \) we denote by \( Y_n \) the set \( \{ j_0, j_1, \ldots, j_{n-1} \} \).

**3.5 Lemma:** For all integer \( n \geq 0 \), the maps \( \varphi_u : \Nil(A,S) \rightarrow \Nil(A,S_u) \), for \( u \in Y_n \) and the map \( \varphi_{j_n} : \Nil(A,S) \rightarrow \Nil(A,S_{j_n}) \) induce a homotopy equivalence of spectra:

\[
G_n : \Nil(A,S) \simto \oplus_{u \in Y_n} \Nil(A,S_u) \oplus \Nil(A,S_{j_n})
\]

**Proof:** We’ll prove the lemma by induction on \( n \). The map \( G_0 \) is the identity (and then a homotopy equivalence).
Suppose \( n \geq 0 \) and \( G_n \) is a homotopy equivalence. Consider the bimodule \( S' = S_i' \oplus S_j' \) with:
\[
S_i' = S_{j_n}, \\
S_j' = S_{J_n \setminus \{j_n\}}
\]
By applying lemma 3.3 with this bimodule, we get a homotopy equivalence of spectra:
\[
\text{Nil}(A, S') = \text{Nil}(A, S_{j_n}) \xrightarrow{\sim} \text{Nil}(A, S_{j_n}) \oplus \text{Nil}(A, \hat{S})
\]
where \( \hat{S} \) is the following bimodule:
\[
\hat{S} = \bigoplus_{u,k} (S_{j_n})^k S_u
\]
the sum being taken over all integer \( k \geq 0 \) and all \( u \neq j_n \) in \( J_n \). So we have isomorphisms:
\[
\hat{S} \simeq \bigoplus_{u,k} S_{j_n u} \simeq \bigoplus_{v \in J_{n+1}} S_v = S_{J_{n+1}}
\]
and then a homotopy equivalence:
\[
\text{Nil}(A, S_{J_n}) \xrightarrow{\sim} \text{Nil}(A, S_{J_n}) \oplus \text{Nil}(A, S_{J_{n+1}})
\]
Therefore we have homotopy equivalences:
\[
\text{Nil}(A, S) \xrightarrow{\sim} \bigoplus_{u \in Y_n} \text{Nil}(A, S_u) \oplus \text{Nil}(A, S_{J_n})
\]
\[
\xrightarrow{\sim} \bigoplus_{u \in Y_n} \text{Nil}(A, S_u) \oplus \text{Nil}(A, S_{J_n}) \oplus \text{Nil}(A, S_{J_{n+1}})
\]
\[
\xrightarrow{\sim} \bigoplus_{u \in Y_{n+1}} \text{Nil}(A, S_u) \oplus \text{Nil}(A, S_{J_{n+1}})
\]
and \( G_{n+1} \) is a homotopy equivalence. The lemma follows by induction. \( \Box \)

We are now able to finish the proof of theorem 5.

As we have said before it is enough to consider the case where \( I \) is finite with at least two elements.

Consider the map \( \Phi : \text{Nil}(A, S) \rightarrow \bigoplus_{u \in Y} \text{Nil}(A, S_u) \) induced by the functors \( \varphi_u : \text{Nil}(A, S) \rightarrow \text{Nil}(A, S_u) \). We have to prove that \( G \) is a homotopy equivalence and, for doing that, it will be enough to prove that \( G \) induces an isomorphism:
\[
\Phi_i : \text{Nil}_i(A, S) \rightarrow \bigoplus_{u \in Y} \text{Nil}_i(A, S_u)
\]
for every integer \( i \in \mathbb{Z} \).

Let \( i \in \mathbb{Z} \) be an integer and \( y \) be an element in \( \bigoplus_{u \in Y} \text{Nil}_i(A, S_u) \). There is an integer \( n \geq 0 \) such that \( y \) is in the direct sum of \( \text{Nil}_i(A, S_u) \), for \( u \in Y_n \). Because of lemma 3.5, there is an element \( x \in \text{Nil}_i(A, S) \) such that:
\[
G_n(x) = y \oplus 0 \in \bigoplus_{u \in Y_n} \text{Nil}_i(A, S_u) \oplus \text{Nil}_i(A, S_{J_n})
\]
Hence $x$ is sent to $y$ by $\Phi_i$ and $\Phi_i$ is surjective.

Suppose $i \geq 0$. Let $x \in \text{Nil}_i(A,S)$ be an element killed by $\Phi_i$. This element can be lifted in an element $y \in K_i(\mathcal{Nil}(A,S)) = \pi_{i+1}(B(\mathcal{Nil}(A,S)))$ and there is a finite subcategory $\mathcal{E}$ of the Quillen category $Q\mathcal{Nil}(A,S)$ such that $y$ can be lifted in an element $z \in \pi_{i+1}(B\mathcal{E})$. This category $\mathcal{E}$ involves only finitely many objects $(M,f) \in \mathcal{Nil}(A,S)$. Denote by $\mathcal{F}$ the set of these morphisms $f$.

Since each $f \in \mathcal{F}$ is nilpotent, there is an integer $p$ such that $f^u$ is trivial for each $f \in \mathcal{F}$ and each element $u \in W(I)$ of length $\geq p$. Because of the last property of lemma 3.4, the set of integers $n$ such that there is some $u \in J_n$ and some $f \in \mathcal{F}$ with $f^u \neq 0$ is finite. Hence, for $n$ big enough, the composite functor

$$\mathcal{E} \rightarrow Q\mathcal{Nil}(A,S) \xrightarrow{\varphi_{J_n}} Q\mathcal{Nil}(A,S_{J_n})$$

factorizes through the category $Q\mathcal{P}_A$ and the composite map

$$\Omega B\mathcal{E} \rightarrow \Omega BQ\mathcal{Nil}(A,S_{J_n}) \rightarrow \text{Nil}(A,S_{J_n})$$

is trivial. Hence $z$ is killed in $\text{Nil}_i(A,S_{J_n})$ and $x \in \text{Nil}_i(A,S)$ is killed by $\varphi_{J_n} : \text{Nil}_i(A,S) \rightarrow \text{Nil}(A,S_{J_n})$.

But $x$ is killed by $\Phi_i$ and $x$ is also killed by the map $\text{Nil}_i(A,S) \rightarrow \bigoplus_{u \in Y_n} \text{Nil}_i(A,S_u)$. Therefore $x$ is killed by $G_n$ which is a homotopy equivalence and $x$ is zero. Hence the morphism $\Phi_i$ is bijective for every integer $i \geq 0$.

If $i$ is a negative integer, we may replace $A$ and $S$ by $\Sigma^p A$ and $\Sigma^p S$ for some $p > -i$ and the bijectivity of $\Phi_{i+p}$ for $\langle \Sigma^p A, \Sigma^p S \rangle$ implies that $\Phi_i$ (for $(A,S)$) is bijective. Hence $\Phi$ is a homotopy equivalence of spectra. Moreover this is true for the set $Y$ and then for every admissible set in $W(I)$. Then we get the desired result and the theorem follows. 

\[\square\]

3.6 Proof of theorem 6.

Denote by $S'$ the following bimodule:

$$S' = S \oplus \bigoplus_i E_i \otimes F_i$$

Let $J$ be the disjoint union of $I$ and $\{0\}$. We set:

$$\forall i \in I, \quad S_i = E_i \otimes_{A_i} F_i = E_i F_i$$

$$S_0 = S$$

and we have:

$$S' = \bigoplus_{j \in J} S_j$$

Because of theorem 5, there exist a family of $A$-bimodules $U_k$, $k \in K$ such that the following holds:

- each $U_k$ is flat on both sides.
• \( \text{Nil}(A, S') \approx \text{Nil}(A, S) \oplus \oplus_{k} \text{Nil}(A, U_k) \)

• each \( U_k \) has the form: \( U_k = S_{j_1}, S_{j_2}, \ldots S_{j_n} \), with \( j_1, j_2, \ldots, j_n \) in \( J \) and \( j_q \in I \) for some \( q \).

Then, because of theorem 4, there exist a family of \( A \)-bimodules \( V_k, k \in K \) and elements \( i_k \in I \) such that

• each \( V_k \) is flat on both sides

• \( \text{Nil}(A, S') \approx \text{Nil}(A, S) \oplus \oplus_{k} \text{Nil}(A, S_k V_k) \)

and we have, for each \( k \):

\[
\text{Nil}(A, S_k V_k) = \text{Nil}(A, E_{i_k} F_{i_k} V_k) \approx \text{Nil}(A_{i_k}, F_{i_k} V_k E_{i_k})
\]

But \( A_{i_k} \) is regular coherent and each spectrum \( \text{Nil}(A_{i_k}, F_{i_k} V_k E_{i_k}) \) is contractible. The result follows. \( \Box \)

3.7 Proof of lemma 3.1.

With the notations of lemma 3.1, we denote by \( F = B \oplus bE_b \oplus (bE_b)^2 \oplus \ldots \) the tensor algebra of \( bE_b \) and by \( \hat{E} \) the bimodule \( \hat{E} = aE_a \oplus aE_b F bE_a \).

For every object \((M, f) \in \mathcal{N}(A \times B, E)\), we set:

\[
g_1 = af_a, \quad g_2 = af_b, \quad g_3 = bf_a, \quad g_4 = bf_b
\]

Since \( f \) is nilpotent, there is an integer \( n > 0 \) such that \( f^n = 0 \). Then, for every integers \( i_1, i_2, \ldots, i_n \) in \( \{1, 2, 3, 4\} \) the morphism \( g_{i_1} g_{i_2} \ldots g_{i_n} \) is a part of \( f^n \) and we have:

\[
g_{i_1} g_{i_2} \ldots g_{i_n} = 0.
\]

Hence the two morphisms \( b f_b \) and \( \hat{f} = a f_a + \sum_{k \geq 0} a f_b (b f_b)^k b f_a \) are nilpotent and we have a functor

\[
\Phi(A, B, E) : \mathcal{N}(A \times B, E) \longrightarrow \mathcal{N}(B, bE_b) \times \mathcal{N}(A, \hat{E})
\]

sending each object \((M, f) \in \mathcal{N}(A \times B, E)\) to:

\[
\Phi(A, B, E)(M, f) = \left( (M_b, b f_b), (M_a, \hat{f}) \right)
\]

Moreover this functor is exact.

It is easy to see that lemma 3.1 is equivalent to the fact that \( \Phi(\Sigma^n A, \Sigma^n B, \Sigma^n E) \) induces, for all \( n \geq 0 \), a homotopy equivalence in K-theory. Therefore it is enough to prove that \( \Phi(A, B, E) \) induces a homotopy equivalence in K-theory for every left-flat bimodule \((A \times B, E)\) such that \( E_b \) is flat on the right and that will be done by using K-theory of Waldhausen categories.

In our situation, we have three exact categories: the categories \( \mathcal{A}, \mathcal{B} \) and \( \mathcal{C} \) of finitely generated projective right modules over the rings \( A, B \) and \( C = A \times B \) respectively. These categories are contained in the corresponding abelian categories \( \mathcal{A}^\vee, \mathcal{B}^\vee \) and \( \mathcal{C}^\vee \) of right modules over the corresponding rings.

If \((A, S)\) is a left-flat bimodule, we have also an exact category \( \mathcal{N}(A, S) \) and a Waldhausen category \( \mathcal{N}(A, S)_* \). Moreover \( \mathcal{N}(A, S) \) is contained in the abelian
category $\mathcal{N}il(A,S)^{\vee}$ (see part 1.3) and, as a subcategory of $\mathcal{N}il(A,S)^{\vee}$, \(\mathcal{N}il(A,S)\) is stable under taking kernel of epimorphisms. Hence the Gillet-Waldhausen theorem applies to the categories $\mathcal{N}il(\cdot,\cdot)$ and we have a commutative diagram:

\[
\begin{array}{ccc}
\mathcal{N}il(A \times B, E) & \xrightarrow{\Phi(A,B,E)} & \mathcal{N}il(B, bE_b) \times \mathcal{N}il(A, \widehat{E}) \\
\downarrow & & \downarrow \\
\mathcal{N}il(A \times B, E)_* & \xrightarrow{\Phi(A,B,E)} & \mathcal{N}il(B, bE_b)_* \times \mathcal{N}il(A, \widehat{E})_*
\end{array}
\]

of Waldhausen categories where the vertical functors induce homotopy equivalences in $K$-theory.

Therefore, in order to prove the lemma, it is enough to prove that the functor:

\[
\Phi(A,B,E)_*: \mathcal{N}il(A \times B, E)_* \longrightarrow \mathcal{N}il(B, bE_b)_* \times \mathcal{N}il(A, \widehat{E})_*
\]

induces a homotopy equivalence in $K$-theory.

If $(A,S)$ is a left-flat bimodule, it is easy to see that an object of $\mathcal{N}il(A,S)_*$ is nothing else but a pair $(M,f)$, where $M$ is in $\mathcal{A}_*$ and $f: M \longrightarrow MS$ is a nilpotent morphism in $\mathcal{A}_*^{\vee}$. Then the functor $\Phi(A,B,E)_*$ is given by:

\[
\Phi(A,B,E)_*(M,f) = ((M_{bE_b},bf_{bE_b}),(Ma,\widehat{f}))
\]

for every $M \in \mathcal{C}_* = \mathcal{A}_* \times \mathcal{B}_*$.

Consider the Waldhausen category $\mathcal{E} = \mathcal{N}il(A \times B, E)_*$. We may define a new subcategory of equivalences by saying that $\varphi: (M, f) \longrightarrow (M', f')$ is an equivalence if the induced morphism $Ma \longrightarrow M_a'$ is an isomorphism in homology. With this new equivalences, we get a new Waldhausen category $\mathcal{E}'$. We have also a Waldhausen subcategory $\mathcal{E}_0$ of $\mathcal{E}$ generated by the objects $(M, f) \in \mathcal{E}$ such that $Ma$ is acyclic. Denote also by $\mathcal{N}il_0$ the Waldhausen subcategory of $\mathcal{N}il(A, \widehat{E})_*$ generated by pairs $(M, f)$ with $M$ acyclic. Hence we have a commutative diagram of essentially small Waldhausen categories:

\[
\begin{array}{ccc}
\mathcal{E}_0 & \longrightarrow & \mathcal{E} & \longrightarrow & \mathcal{E}' \\
\Phi_0 & & \Phi(A,B,E) & & \Phi' \\
\downarrow & & \downarrow & & \downarrow \\
\mathcal{N}il(B, bE_b)_* \times \mathcal{N}il_0 & \longrightarrow & \mathcal{N}il(B, bE_b)_* \times \mathcal{N}il(A, \widehat{E})_* & \longrightarrow & \mathcal{N}il(A, \widehat{E})_*
\end{array}
\]

Since every morphism in $\mathcal{N}il_0$ is an equivalence, the category $\mathcal{N}il_0$ has trivial $K$-theory and, because of the fibration theorem, the two lines of the diagram induce
fibrations in K-theory. Hence in order to prove the lemma, it’s enough to prove that $\Phi_0$ and $\Phi'$ induce homotopy equivalences on K-theory and that’s equivalent to show that $\Phi'$ and the functor:

$$\Phi'_0: E_0 \xrightarrow{\Phi_0} \mathcal{N}(B, bE_b)_* \times \mathcal{N}(B, bE_b)_* \xrightarrow{pr_1} \mathcal{N}(B, bE_b)_*$$

induce homotopy equivalences on K-theory. Moreover these two functors have the approximation properties (App1).

**3.8 Lemma:** The functor $\Phi'_0$ induces a homotopy equivalence in K-theory.

**Proof:** Because of the approximation theorem 2.3, we just have to prove that $\Phi'_0$ has the property (App2).

Let $X = (M, f) \in E_0$ and $Y = (Q, g) \in \mathcal{N}(B, bE_b)_*$ be two objects in the corresponding categories. A morphism $\varphi : \Phi'_0(X) \to Y$ is represented by a morphism $\varphi : M_b \to Q$ in $\mathcal{B}_*$ making the following diagram commutative:

$$
\begin{array}{ccc}
M_b & \xrightarrow{\varphi} & Q \\
\downarrow b_f & & \downarrow g \\
M_{bE_b} & \xrightarrow{\varphi} & Q_{bE_b}
\end{array}
$$

Denote by $C$ the cylinder of $\varphi$ and by $C'$ its mapping cone (or its 0-cone as defined in 2.1). The morphisms $b_f$ and $g$ induce two nilpotent morphisms $\lambda : C \to C_{bE_b}$ and $\lambda' : C' \to C'_{bE_b}$. By naturality, we have a commutative diagram in $\mathcal{C}_{*'}$:

$$
\begin{array}{ccc}
M_b & \xrightarrow{i} & C & \xrightarrow{p} & Q \\
\downarrow b_f & & \downarrow \lambda & & \downarrow g \\
M_{bE_b} & \xrightarrow{i} & C_{bE_b} & \xrightarrow{p} & Q_{bE_b}
\end{array}
$$

where $i : M_b \to C$ is a cofibration and $p : C \to Q$ a homotopy equivalence. Moreover we have: $\varphi = pi$.

Define the object $M' \in \mathcal{C}_*$ by: $M'_a = M_a$ and $M'_b = C$. In order to define the desired object $X' \in \mathcal{E}_0$, we have to construct the morphism $f' : M' \to M'E$.

We set: $a f' = a f_a$, $b f' = \lambda$ and $b f'_a = i \cdot b f_a$. Since $i : M_b \to C$ is a cofibration and $M_a_{aE_b}$ is acyclic, there is no obstruction to extend $a f_b : M_b \to M_a_{aE_b}$ to a morphism: $a f'_b : C \to M_a_{aE_b}$. Hence we get a morphism $f' : M' \to M'E$. 

50
Let $C$ be the finite complex in $\mathcal{C}$ defined by: $C_a = 0$ and $C_b = C'$ and $\bar{\lambda} : \overline{C} \longrightarrow \overline{C}E$ be the morphism in $\mathcal{C}_\ast$ associated with $\lambda'$ under the canonical bijection: $\text{Hom}_{\mathcal{C}_\ast}(\overline{C}, \overline{C}E) \simeq \text{Hom}_{\mathcal{C}_\ast}(C', C_b E_b)$. Since $\lambda'$ is nilpotent, $\bar{\lambda}$ is also nilpotent. We have a commutative diagram in $\mathcal{C}_\ast$ with exact rows:

$$
\begin{array}{ccccccccc}
0 & \longrightarrow & M & \longrightarrow & M' & \longrightarrow & \overline{C} & \longrightarrow & 0 \\
& & f \downarrow & & f' \downarrow & & \bar{\lambda} \downarrow & & \\
0 & \longrightarrow & ME & \longrightarrow & M'E & \longrightarrow & \overline{C}E & \longrightarrow & 0
\end{array}
$$

and, since $f$ and $\bar{\lambda}$ are nilpotent, $f'$ is nilpotent also. More precisely, if we have: $f^p = 0$ and $\bar{\lambda}^q = 0$, then we have $f'^{p+q} = 0$. Since $M'_a$ is acyclic, $X' = (M', f')$ is an object in $\mathcal{E}_0$ and the morphism $i$ induces a morphism $\alpha : X \longrightarrow X'$. Moreover we have the following commutative diagram:

$$
\begin{array}{cccc}
\Phi'_0(X) & \longrightarrow & Y \\
\alpha \downarrow & & \downarrow \\
\Phi_0'(X') & \longrightarrow & Y
\end{array}
$$

and the property (App2) is satisfied. The lemma follows. □

So the last thing to do is to prove that the functor $\Phi' : \mathcal{E}' \longrightarrow \mathcal{N}il(A, \widehat{E})_{\ast}$ induces a homotopy equivalence in K-theory. As before, it’s enough to prove that $\Phi'$ has the property (App2). In order to do that we’ll need two technical results:

**3.9 Lemma:** Let $A$ and $B$ be two rings and $S$ be an $(A, B)$-bimodule. Suppose $S$ is flat on the left. Let $X$ be a finite $B$-complex, $Y$ be an $A$-complex and $f : X \longrightarrow YS$ be a morphism of $B$-complexes. Then there exist a finite $A$-complex $Y'$, a morphism $g : Y' \longrightarrow Y$ and a commutative diagram:

$$
\begin{array}{cccc}
X & \longrightarrow & Y'S \\
\downarrow & & \downarrow \scriptstyle{g} \\
X & \longrightarrow & YS
\end{array}
$$
3.10 Lemma: Let $A$ be a ring, $X$ and $Y$ two $A$-complexes and $f: X \to Y$ be a morphism. Suppose the module $\oplus_{n} X_n$ is finitely presented and each $Y_n$ is flat. Then $f$ factorizes through a finite $A$-complex.

These two lemmas will be proven at the end of the section.

As a consequence of these two lemmas we have the following result:

3.11 Lemma: Let $A$, $B$ and $C$ be three rings, $S$ be a $(C,B)$-bimodule and $T$ be a $(B,A)$-bimodule. Suppose $S$ is flat on the right and $T$ is flat on the left. Let $X$, $Y$ and $Z$ be finite complexes over the rings $A$, $B$ and $C$ respectively and $f: X \to YT$ and $g: Y \to ZS$ be two morphisms. We suppose that the composite morphism:

$$X \xrightarrow{f} YT \xrightarrow{g} ZST$$

is zero. Then the morphism $g: Y \to ZS$ factorizes through a finite complex $Y'$ by a morphism $\lambda: Y \to Y'$ in such a way that the composite morphism:

$$X \xrightarrow{f} YT \xrightarrow{\lambda} Y'T$$

is zero.

Proof: Let $K$ be the kernel of $g$. Since $T$ is flat on the left we have two exact sequences:

$$0 \to K \xrightarrow{i} Y \xrightarrow{g} ZS$$

$$0 \to KT \xrightarrow{i} YT \xrightarrow{g} ZST$$

and the morphism $f$ factorizes through $KT$. Because of lemma 3.9 there exist a finite $B$-complex $K'$, a morphism $j: K' \to K$ and a commutative diagram:

\[
\begin{array}{ccc}
X & \xrightarrow{f'} & K'T \\
\downarrow & & \downarrow i \\
X & \xrightarrow{f} & YT
\end{array}
\]

Denote by $Y_1$ the cokernel of $ij: K' \to Y$. Since $gi$ is the zero morphism, there
is a morphism \( g_1 : Y_1 \to ZS \) making the following diagram commutative:

\[
\begin{array}{ccc}
Y & \xrightarrow{g} & ZS \\
\downarrow & & \downarrow \\
Y_1 & \xrightarrow{g_1} & ZS
\end{array}
\]

Since \( S \) is flat on the right, \( ZS \) is flat and, because of lemma 3.10, \( g_1 \) factorizes through a finite complex \( Y' \). The lemma follows. \( \square \)

**3.12 Lemma:** The functor \( \Phi' : \mathcal{E}' \to \mathcal{Nil}(A, \hat{E})_\ast \) has the property (App2).

**Proof:** Let’s set:

\[
H = aE_a \quad K = bE_b \quad S = aE_a \quad T = bE_a \quad \hat{K} = F = B \oplus K \oplus K^2 \oplus \ldots
\]

Let \( X \) and \( Y \) be two objects in \( \mathcal{Nil}(A \times B, E)_\ast \) and \( \mathcal{Nil}(A, \hat{E})_\ast \) respectively and \( \varphi \) be a morphism from \( \Phi'(X) \) to \( Y \). By setting: \( (U, f) = X, (M, g) = Y, P = U_a, Q = U_b \), we see that \( P \) and \( M \) are finite \( A \)-complexes, \( Q \) is a finite \( B \)-complex, \( \varphi \) is a morphism from \( P \) to \( M \) and \( g \) is written as a finite sum:

\[
g = \lambda + \sum_{k \geq 0} \mu_k
\]

where \( \lambda \) is a morphism from \( M \) to \( MH \) and each \( \mu_k \) is a morphism from \( M \) to \( MSK^kT \). Moreover the following diagrams are commutative:

\[
\begin{array}{ccc}
P & \xrightarrow{\varphi} & M \\
a_\lambda & & a_{f_b(bf_b)^k} \downarrow \mu_k \\
PH & \xrightarrow{\varphi} & MH & PSK^kT & \xrightarrow{\varphi} & MSK^kT
\end{array}
\]

We want to construct an object \( X' \in \mathcal{Nil}(A \times B, E)_\ast \) and a morphism \( \alpha : X \to X' \) such that \( \Phi'(\alpha) : \Phi'(X) \to \Phi'(X') \) is isomorphic to \( \varphi : \Phi'(X) \to Y \). So we want to have: \( X' = (U', f') \) and \( U'_a = M \) and, to determine \( X' \), we need to define \( Q' = U'_b \), the morphism \( f' \) and the morphism \( \alpha : Q \to Q' \). Actually, \( Q' \) will be constructed as a direct sum: \( Q' = \bigoplus_{i \geq 0} Q_i \) such that \( bf'_b(Q_{i+1}) \) is contained in \( Q_i K \) for all \( i \geq 0 \) and is zero for \( i = -1 \) and \( a_{f'_b} \) vanishes on each \( Q_i \), for \( i > 0 \).
So we need to define finite $B$-complexes $Q_i$, a morphism $e : Q_0 \to MS$ and morphisms $\alpha_i : Q \to Q_i$, $\theta_i : Q_{i+1} \to Q_i K$ and $\beta_i : M \to Q_i T$ (with $Q_i = 0$ for $i$ big enough) and the morphism $f'$ is defined by:

$$a f'_a = \lambda, \quad b f'_b = \sum_{i \geq 0} \theta_i, \quad b f'_b = \sum_{i \geq 0} \beta_i, \quad a f'_b = e pr_0$$

where $pr_0 : Q' \to Q_0$ is the projection. The morphism $\alpha$ is equal to $\varphi : P \to M$ on $P$ and to $\sum_{i \geq 0} \alpha_i : Q \to Q'$ on $Q$.

But we have two conditions: the fact that $\alpha$ is a morphism and the equality: $\Phi'(X') = Y$. These conditions are equivalent to:

$$\varphi a f_b = e \alpha_0$$
$$\alpha_i b f_a = \beta_i \varphi$$
$$\theta_i \alpha_{i+1} = \alpha_i b f_b$$
$$\mu_i = e \theta_0 \theta_1 \ldots \theta_{i-1} \beta_i$$

for all $i \geq 0$.

For technical reasons, we introduce the morphism $e_i = e \theta_0 \theta_1 \ldots \theta_{i-1}$ from $Q_i$ to $MSK^i$. Then we have to construct, for each $i \geq 0$, the complex $Q_i$ and morphisms $e_i : Q_i \to MSK^i$, $\alpha_i : Q \to Q_i$, $\beta_i : M \to Q_i T$ and $\theta_i : Q_{i+1} \to Q_i K$, with the following properties:

$$A(i) : \varphi a f_b (b f_b)^i = e_i \alpha_i$$
$$B(i) : \alpha_i b f_a = \beta_i \varphi$$
$$C(i) : \theta_i \alpha_{i+1} = \alpha_i b f_b$$
$$D(i) : \mu_i = e_i \beta_i$$
$$E(i) : e_{i+1} = e_i \theta_i$$

for all $i \geq 0$.

Since the sum of the $\mu_k$’s is finite, there is an integer $n > 0$ such that: $\mu_i = 0$ for all $i > n$.

So we’ll construct $(Q_i, e_i, \alpha_i, \beta_i, \theta_i)$ by induction. Let $i \geq 0$ be an integer and suppose that $(Q_j, e_j, \alpha_j, \beta_j, \theta_j)$ is defined for all $j > i$ such that the properties $A(j)$, $B(j)$, $C(j)$, $D(j)$, $E(j)$, are satisfied for all $j > i$. We begin this induction with $i = n$ by setting: $Q_j = 0$ for all $j > n$.

We have to construct $Q_i$ and morphisms $e_i$, $\alpha_i$, $\beta_i$ and $\theta_i$.

Consider the following morphisms:

$$\varphi a f_b (b f_b)^i : Q \to MSK^i$$
$$\mu_i : M \to MSK^i T$$
$$e_{i+1} : Q_{i+1} \to MSK^{i+1}$$

These morphisms induce a morphism $h : Q \oplus M \oplus Q_{i+1} \to MSK^i (B \oplus T \oplus K)$ and, because of lemma 3.9, there are a finite complex $Q_i$, a morphism $e_i : Q_i \to MSK^i$
and a commutative diagram:

\[
\begin{array}{ccc}
Q \oplus M \oplus Q_{i+1} & \overset{h'}{\longrightarrow} & Q_i(B \oplus T \oplus K) \\
\downarrow & & \downarrow e_i \\
Q \oplus M \oplus Q_{i+1} & \overset{h}{\longrightarrow} & MSK^i(B \oplus T \oplus K)
\end{array}
\]

The morphism \( h' \) induces morphisms:

\[
\begin{aligned}
\alpha_i : Q & \longrightarrow Q_i \\
\beta_i : M & \longrightarrow Q_i T \\
\theta_i : Q_{i+1} & \longrightarrow Q_i K
\end{aligned}
\]

and properties \( A(i), D(i), (E(i) \) are satisfied. Denote by \( u \) and \( v \) the defaults of properties \( B(i) \) and \( C(i) \):

\[
\begin{aligned}
u & = \beta_i \varphi - \alpha_i b \varphi \\
v & = \alpha_i b \varphi - \theta_i \alpha_{i+1}
\end{aligned}
\]

Because of properties \( A(i) \) and \( D(i) \), we have:

\[
e_i u = e_i \beta_i \varphi - e_i \alpha_i b \varphi = \mu_i \varphi - \varphi a f_b (b f_b) \theta_i b \varphi = 0
\]

and, because of properties \( A(i), E(i) \) and \( A(i+1) \), we have:

\[
e_i v = e_i \alpha_i b f_b - e_i \theta_i \alpha_{i+1} = \varphi a f_b (b f_b) \theta_i b \varphi = 0
\]

Since a tensor product of bimodules which are flat on the right is flat on the right, we can apply the lemma 3.11 to morphisms \( u \oplus v : P \longrightarrow Q_i(T \oplus K) \) and \( e_i : Q_i \longrightarrow MSK^i \). Thus \( e_i \) factorizes through a finite complex \( Q'_i \) by a morphism \( \varepsilon : Q_i \longrightarrow Q'_i \) such that: \( \varepsilon (u \oplus v) = 0 \).

Hence, up to replacing \( Q_i \) by \( Q'_i \), we may as well suppose that \( A(i), B(i), C(i), D(i), E(i) \) are satisfied. Therefore \( Q_i, e_i, \alpha_i, \beta_i, \theta_i \) are defined and \( A(i), B(i), C(i), D(i), E(i) \) are satisfied for all \( i \geq 0 \).

Then the finite complex \( Q' = \bigoplus_{i \geq 0} Q_i \) is constructed and the morphism \( f' \) is defined by:

\[
\begin{aligned}
a f'_a & = \lambda \\
b f'_b & = \bigoplus_{i \geq 0} \theta_i \\
a f'_b & = e_0 pr_0 \\
b f'_a & = \bigoplus_{i \geq 0} \beta_i
\end{aligned}
\]
Hence the desired object $X'$ is constructed and $\Phi'$ has the approximation property (App2). The lemma follows and then follow lemma 3.1 and theorems 4, 5 and 6. □

3.13 Proof of lemma 3.9.

The situation is the following: $(A,S)$ is a left-flat bimodule, $X$ is a finite $A$-complex, $Y$ is an $A$-complex and $f : X \rightarrow YS$ is a morphism of $A$-complexes. We want to construct a finite $A$-complex $Y'$ and a morphism $Y' \rightarrow Y$ such that $f : X \rightarrow YS$ factorizes through $Y'S$.

For each integer $n$, denote by $X(n)$ the $n$-skeleton of $X$. Let $n$ be an integer. Suppose the $n$-skeleton $Y'(n)$ of $Y'$ is constructed in such a way that we have a morphism $g_n : Y'(n) \rightarrow Y$ and a commutative diagram:

$$
\begin{array}{ccc}
X(n) & \xrightarrow{h_n} & Y'(n)S \\
\downarrow & & \downarrow g_n \\
X(n) & \xrightarrow{f} & YS \\
\end{array}
$$

(D_n)

If $n$ is small enough, $X(n)$ is null and $Y'(n)$ can be chosen to be zero.

Denote by $Z_n$ the kernel of the morphism $d : Y'_n \rightarrow Y'_{n-1}$ and by $U_{n+1}$ the module defined by the cartesian square:

$$
\begin{array}{ccc}
U_{n+1} & \xrightarrow{\alpha} & Y_{n+1} \\
\downarrow & & \downarrow d \\
Z_n & \xrightarrow{g_n} & Y_b \\
\end{array}
$$

The composite morphism $X_{n+1} \xrightarrow{d} X_n \xrightarrow{h_n} Y'_nS$ takes values in $Z_nS$ and induces, together with the morphism $f : X_{n+1} \rightarrow Y_{n+1}S$, a well defined morphism $\lambda : X_{n+1} \rightarrow U_{n+1}$. So we get a commutative diagram:

$$
\begin{array}{ccc}
X_{n+1} & \xrightarrow{\lambda} & U_{n+1}S \\
\downarrow d & & \downarrow \gamma \\
X_n & \xrightarrow{h_n} & Y'_nS \\
\downarrow & & \downarrow g_n \\
X_n & \xrightarrow{h_n} & Y'_nS \\
\end{array}
$$

56
where $\gamma$ is the composite morphism $U_{n+1} \xrightarrow{\beta} Z_n \subset Y'_n$.

Since $X_{n+1}$ is finitely generated, there is a finitely generated submodule $M$ in $U_{n+1}$ such that $\lambda(X_{n+1})$ is contained in $MS$. Let $Y'_{n+1}$ be a finitely generated projective $A$-module and $\mu : Y'_{n+1} \to M$ be an epimorphism. Since $X_{n+1}$ is projective, the morphism $\lambda : X_{n+1} \to Y'_n$ can be lifted in a morphism $X_{n+1} \to Y'_{n+1}S$ and we get a commutative diagram:

\[
\begin{array}{ccc}
X_{n+1} & \xrightarrow{h} & Y'_{n+1}S \\
\downarrow d & & \downarrow d \\
X_n & \xrightarrow{\alpha} & Y'_nS \\
\end{array}
\]

where $d : Y'_{n+1} \to Y'_n$ is the morphism $\gamma\mu$ and $g : Y'_{n+1} \to Y_{n+1}$ is the morphism $\alpha\mu$.

Thus we have constructed the complex $Y'(n+1)$ and the commutative diagram $(D_{n+1})$. By induction we have $Y'(n)$ and the commutative diagram $(D_n)$ for every integer $n$ and, for $n$ big enough, $Y'(n)$ and the diagram $(D_n)$ is a solution of the problem. \hfill \Box

### 3.14 Proof of lemma 3.10.

In the lemma, $f : X \to Y$ is a morphism between two $A$-complexes, the direct sum of the $X'_n$s if finitely presented and each $Y'_n$ is flat.

For every $A$-complex $E$, denote by $E^n$ its $n$-coskeleton i.e. the quotient of $E$ by its $(n-1)$–skeleton.

Let $n$ be an integer. Suppose that the $n$-coskeleton $F^n$ of a finite complex $F$ is constructed in such a way that the morphism $f : X^n \to Y^n$ induced by $f : X \to Y$ factorizes through $F^n$ via two morphisms $\alpha : X^n \to F^n$ and $\beta : F^n \to Y^n$. If $n$ is big enough $X^n$ is trivial and we may set: $F^n = 0$.

We have a commutative diagram:

\[
\begin{array}{ccc}
X_{n+1} & \xrightarrow{\alpha} & F_{n+1} \\
\downarrow d & & \downarrow d \\
X_n & \xrightarrow{\alpha} & F_n \\
\end{array}
\]

\]

\[
\begin{array}{ccc}
F_{n+1} & \xrightarrow{\beta} & Y_{n+1} \\
\downarrow d & & \downarrow d \\
F_n & \xrightarrow{\beta} & Y_n \\
\end{array}
\]
Let $E$ be the $A$-module defined by the cocartesian square:

$$
\begin{array}{ccc}
X_n & \longrightarrow & F'_n \\
 d & \downarrow & \downarrow \\
X_{n-1} & \longrightarrow & E
\end{array}
$$

where $F'_n$ is the cokernel of the morphism $d : F_{n+1} \longrightarrow F_n$. Since $X_n$, $X_{n-1}$ and $F'_n$ are finitely presented, the $A$-module $E$ is also finitely presented.

We have a commutative diagram:

$$
\begin{array}{ccc}
X_{n+1} & \overset{\alpha}{\longrightarrow} & F_{n+1} & \overset{\beta}{\longrightarrow} & Y_{n+1} \\
 d & \downarrow & d & \downarrow & d \\
X_n & \overset{\alpha}{\longrightarrow} & F_n & \overset{\beta}{\longrightarrow} & Y_n \\
 d & \downarrow & \delta & \downarrow & d \\
X_{n-1} & \longrightarrow & E & \longrightarrow & Y_{n-1}
\end{array}
$$

where the composite morphism $F_{n+1} \overset{d}{\longrightarrow} F_n \longrightarrow E$ is trivial.

But $E$ is finitely presented and $Y_{n-1}$ is flat. Therefore the morphism $E \longrightarrow Y_{n-1}$ factorizes through a finitely generated projective $A$-module $F_{n-1}$ and, together with the composite morphism $F_n \overset{\delta}{\longrightarrow} E \longrightarrow F_{n-1}$, we get the desired finite complex $F^{n-1}$ and a commutative diagram:

$$
\begin{array}{ccc}
X^{n-1} & \overset{\alpha}{\longrightarrow} & F^{n-1} & \overset{\beta}{\longrightarrow} & Y^{n-1} \\
 & \downarrow & & \downarrow & \\
X^n & \overset{\alpha}{\longrightarrow} & F^n & \overset{\beta}{\longrightarrow} & Y^n
\end{array}
$$

So we construct the complexes $F^n$ inductively and, for $n$ small enough, the morphism $f : X \longrightarrow Y$ factorizes through the finite complex $F = F^n$. \hfill \Box

**Remark:** It is not clear that the right flatness condition is necessary in theorems 4, 5 and 6. Actually this condition is only used in order to prove that the functor
Φ′ : ℋ → Nil(A, E), (in the proof of lemma 3.1) is a homotopy equivalence. The proof given here needs the right flatness condition (in the lemma 3.10) but another proof without this condition is still possible.

4 Whitehead spectra.

If E is an Ω-spectrum and X is a space, we denote by H(X, E) the Ω-spectrum associated to the smash product X ∧ E. For every i ∈ Z, we have:

\[ \pi_i(H(X, E)) \simeq H_i(X, E) \]

In [Wa1], section 15, Waldhausen associates to any ring R and any group G an assembly map: H(BG, K(R)) → K(R[G]) which is a map of infinite loop spaces. This assembly map induces assembly maps H(BG, Σ^n K(R)) → K(Σ^n R[G]) and then an assembly map h : H(BG, K(R)) → K(R[G]) which is a map of spectra. So we get a fibration of spectra:

\[ H(BG, K(R)) \xrightarrow{h} K(R[G]) \xrightarrow{} Wh^R(G) \]

The spectrum Wh^R(G) is called the Whitehead spectrum of G relative to R.

For every integer i, we set:

\[ Wh_i(G) = \pi_i(Wh^Z(G)) \]

For i < 0, the group Wh_i(G) is isomorphic to K_i(Z[G]) and we have exact sequences:

\[
\begin{align*}
0 & \rightarrow Z \rightarrow K_0(Z[G]) \rightarrow Wh_0(G) \rightarrow 0 \\
0 & \rightarrow Z/2 \oplus H_1(G, Z) \rightarrow K_1(Z[G]) \rightarrow Wh_1(G) \rightarrow 0
\end{align*}
\]

More precisely, Wh_0(G) is the reduced K_0-group of Z[G], Wh_1(G) is the classical Whitehead group of G and Wh_2(G) is the second Whitehead group of G as defined in [HW].

Following Waldhausen, a group G is said to be regular noetherian (resp. regular coherent) if, for every ring R which is regular noetherian on the right, R[G] is regular noetherian (resp. regular coherent) on the right. Since R^{op}[G] is isomorphic to (R[G])^{op}, this condition is equivalent to the condition obtained by replacing right by left. We denote also by ℧ the category of groups and monomorphisms of groups.

4.1 Proposition: We have the following properties:

- If G is the amalgamated free product of a diagram in ℧:

\[
\begin{array}{ccc}
H & \rightarrow & G_1 \\
\downarrow & & \downarrow \\
& G_2 & 
\end{array}
\]
where $G_1$ and $G_2$ are regular coherent and $H$ regular noetherian, then $G$ is regular coherent.

- If $G$ is the HNN extension of a diagram in $\mathcal{G}$:
  \[
  H \xrightarrow{\alpha} G_1 \xleftarrow{\beta}
  \]
  where $G_1$ is regular coherent and $H$ is regular noetherian, then $G$ is regular coherent.

- If $G$ is the colimit of a filtered system $G_i$ in $\mathcal{G}$, where each $G_i$ is regular coherent, then $G$ is regular coherent.

- A subgroup of a regular coherent group is regular coherent.

**Proof:** All these properties are proven in [Wa1] (in theorem 19.1) except the third one.

Let $G$ be the colimit of a filtered system $G_i$ in $\mathcal{G}$ and $R$ be a ring which is regular noetherian on the right. Suppose each $G_i$ is regular coherent. Set: $A = R[G]$ and $A_i = R[G_i]$.

Each ring $A_i$ is regular coherent on the right and for each $i \in I$, the ring $A$ is free on the left over $A_i$.

Let $M$ be a finitely presented right $A$-module. We have an exact sequence of right $A$-modules:
\[
F_1 \xrightarrow{f} F_0 \rightarrow M \rightarrow 0
\]
where $F_0$ and $F_1$ are finitely generated free $A$-modules. The morphism $f$ is represented by a finite matrix with entries in $A$. Since $A$ is the colimit of the $A_i$’s, there is an element $i \in I$ such that $A_i$ contains all the entries of $f$. Therefore $f$ comes from a finite matrix with entries in $A_i$ and there exist a finitely presented right $A_i$-module $M'$ and an isomorphism $M' \otimes_{A_i} A \cong M$.

Since $A_i$ is regular coherent on the right we have an exact sequence of right $A_i$-modules:
\[
0 \rightarrow C_n \rightarrow C_{n-1} \rightarrow \ldots \rightarrow C_0 \rightarrow M' \rightarrow 0
\]
where each $C_k$ is finitely generated projective. Since $A$ is free on the left over $A_i$, we have an exact sequence of right $A$-modules:
\[
0 \rightarrow \begin{array}{c}
\bigoplus_{i}^{} C_{n_i} \\
\bigoplus_{i}^{} C_{n_i-1} \\
\ldots \\
\bigoplus_{i}^{} C_0 \\
\bigoplus_{i}^{} M'
\end{array} \rightarrow M \rightarrow 0
\]
But each $C_k \otimes_{A_i} A$ is finitely generated projective right $A$-module. Therefore every finitely presented $A$-module has a finite resolution by finitely generated projective $A$-modules and $A$ is regular coherent. The result follows.

Let $\text{Cl}$ be the class of groups defined by Waldhausen in [Wa1]. This class is the smallest class of groups satisfying the following:
- The trivial group belongs to $\text{Cl}$. 

60
• If $G$ is the amalgamated free product of a diagram in $\mathcal{G}$:

$$
\begin{array}{c}
H \\ \downarrow \\
G_2
\end{array} \longrightarrow 
\begin{array}{c}
G_1 \\
\downarrow
\end{array}$$

where $G_1$ and $G_2$ are in $\text{Cl}$ and $H$ regular coherent, then $G$ belongs to $\text{Cl}$.

• If $G$ is the HNN extension of a diagram in $\mathcal{G}$:

$$
\begin{array}{c}
H \\ \xymatrix{\alpha \ar[r] & G_1 \ar[d]^-{\beta} \\
G_2}
\end{array}
$$

where $G_1$ is in $\text{Cl}$ and $H$ is regular coherent, then $G$ belongs to $\text{Cl}$.

• If $G$ is the colimit of a filtered system $G_i$ in $\mathcal{G}$, where each $G_i$ is in $\text{Cl}$, then $G$ belongs to $\text{Cl}$.

This class contains free groups, torsion free abelian groups, poly-$\mathbb{Z}$-groups, torsion free one-relator groups and fundamental groups of many low-dimensional manifolds. It is also closed under taking subgroups. See theorem 19.5 in [Wa1].

4.2 Theorem: For every group $G$ in $\text{Cl}$ and every ring $R$ which is regular noetherian on the right, the Whitehead spectrum $\overline{Wh}^R(G)$ is contractible.

Proof: This is essentially theorem 19.4 in [Wa1]. We just have to replace spaces $\text{Nil}(A,S)$ by spectra $\text{Nil}(A,S)$. Since all these spectra are contractible, the result follows.

We’ll construct a class of groups $\text{Cl}_1$ obtained by replacing the condition ”$H$ is regular coherent” (in the definition of $\text{Cl}$) by a weaker condition in such a way that theorem 4.2 is still true for groups in $\text{Cl}_1$.

Consider a diagram of groups:

$$
\begin{array}{c}
H \\ \beta \\
\downarrow
\end{array} \longrightarrow 
\begin{array}{c}
G_1 \\
\downarrow
\end{array}$$

We say that this diagram is regular coherent if the following holds:

• $\alpha$ and $\beta$ are monomorphisms
for every \( x \in G_1 \setminus \alpha(H) \) and every \( y \in G_2 \setminus \beta(H) \), the intersection of the two groups \( \alpha^{-1}(x\alpha(H)x^{-1}) \) and \( \beta^{-1}(y\beta(H)y^{-1}) \) is regular coherent.

Consider a diagram of groups:

\[
H \xrightarrow{\alpha} G_1 \xleftarrow{\beta} G_2
\]

We say that this diagram is regular coherent if the following holds:

- \( \alpha \) and \( \beta \) are monomorphisms
- for every \( x \in G_1 \setminus \alpha(H) \) and every \( y \in G_2 \setminus \beta(H) \), the intersection of the two groups \( \alpha^{-1}(x\alpha(H)x^{-1}) \) and \( \beta^{-1}(y\beta(H)y^{-1}) \) is regular coherent.
- for every \( x \in G_1 \), the group \( \beta^{-1}(x\alpha(H)x^{-1}) \) is regular coherent.

Since the condition "regular coherent" is stable under taking subgroups, it is easy to see that diagrams above are regular coherent if the subgroup \( H \) is regular coherent.

So we define the class \( Cl_1 \) as the smallest class of groups satisfying the following:

- The trivial group belongs to \( Cl_1 \).
- If \( G \) is the amalgamated free product of a diagram \( D \):

\[
H \xrightarrow{\alpha} G_1 \xleftarrow{\beta} G_2
\]

where \( G_1 \) and \( G_2 \) are in \( Cl_1 \) and \( D \) is regular coherent, then \( G \) belongs to \( Cl_1 \).

- If \( G \) is the HNN extension of a diagram \( D' \):

\[
H \xrightarrow{\alpha} G_1 \xleftarrow{\beta}
\]

where \( G_1 \) is in \( Cl_1 \) and \( D' \) is regular coherent, then \( G \) belongs to \( Cl_1 \).

- If \( G \) is the colimit of a filtered system \( G_i \) in \( \mathcal{G} \), where each \( G_i \) is in \( Cl_1 \), then \( G \) belongs to \( Cl_1 \).

4.3 Theorem: Let \( R \) be a ring which is regular noetherian on the right and \( G \) be the amalgamated free product of a regular coherent diagram of groups:

\[
H \xrightarrow{\alpha} G_1 \xleftarrow{\beta} G_2
\]
Then this diagram induces a homotopically cartesian diagram of spectra:

$$
\begin{array}{ccc}
W h^R(H) & \xrightarrow{\alpha} & W h^R(G_1) \\
\downarrow{\beta} & & \downarrow \\
W h^R(G_2) & \longrightarrow & W h^R(G)
\end{array}
$$

4.4 Theorem: Let $R$ be a ring which is regular noetherian on the right and $G$ be the HNN extension of a regular coherent diagram of groups:

$$
H \xrightarrow{\alpha} G_1
$$

Then this diagram induces a homotopy fibration of spectra:

$$
W h^R(H) \xrightarrow{f} W h^R(G_1) \longrightarrow W h^R(G)
$$

where $f$ is the difference (in $\Omega sp$) of maps induced by $\alpha$ and $\beta$.

Proofs of theorems 4.3 and 4.4: In the amalgamated case, we have a commutative diagram of spectra:

$$
\begin{array}{ccc}
H(BH, K(R)) & \xrightarrow{\alpha \oplus - \beta} & H(BG_1, K(R)) \oplus H(BG_2, K(R)) \\
\downarrow & & \downarrow \\
K(R[H]) & \xrightarrow{\alpha \oplus - \beta} & K(R[G_1]) \oplus K(R[G_2]) \\
\end{array}
$$

where horizontal lines are fibrations and vertical maps are assembly maps. Moreover theorem 2 implies a homotopy equivalence:

$$
K(R[G]) \simeq K(R[G])' \oplus \Omega^{-1} \text{Nil}(R[H] \times R[H], S)
$$

for some $R[H] \times R[H]$ bimodule $S$. Therefore we have a fibration:

$$
W h^R(H) \longrightarrow W h^R(G_1) \oplus W h^R(G_2) \longrightarrow W h^R(G)'
$$

and a homotopy equivalence:

$$
W h^R(G) \simeq W h^R(G)' \oplus \Omega^{-1} \text{Nil}(R[H] \times R[H], S)
$$

63
We can do the same for the HNN extension and we get a fibration:

\[ Wh^R(H) \xrightarrow{f} Wh^R(G_1) \longrightarrow Wh^R(G') \]

and a homotopy equivalence:

\[ Wh^R(G) \simeq Wh^R(G') \oplus \Omega^{-1} \text{Nil}(R[H] \times R[H], S) \]

for some \( R[H] \times R[H] \) bimodule \( S \).

Hence the only thing to do is to prove that \( \text{Nil}(R[H] \times R[H], S) \) is contractible.

Let’s denote by \( C \) the ring \( R[H] \). With the notations of 1.4, the bimodule \( S \) is determined by four \( C \)-bimodules \( iS_j \) (with \( i, j \in \{1, 2\} \)). In order to describe these bimodules we’ll introduce the following terminology:

Let \( G \) be a group. A \( G \)-biset is a set \( X \) equipped with two compatible actions of \( G \), one on the left and the other one on the right. We say that a \( G \)-biset \( X \) is free if both actions on \( X \) are free. If \( R \) is a ring, \( R[X] \) is naturally a \( R[G] \)-bimodule and, if \( X \) is free, \( R[X] \) is free on both sides. For any free \( G \)-biset \( X \) and any ring \( R \), we set:

\[ N \text{il}^R(G, X) = N \text{il}(R[G], R[X]) \]

If \( G_1 \) and \( G_2 \) are two groups, we can also define a \( (G_1, G_2) \)-biset as a set equipped with two compatible actions: a left action of \( G_1 \) and a right action of \( G_2 \). Then, for every ring \( R \) and any \( (G_1, G_2) \)-biset \( X \), \( R[X] \) is a \( (R[G_1], R[G_2]) \)-bimodule.

Consider the amalgamated case. We have two monomorphisms \( \alpha : H \longrightarrow G_1 \) and \( \beta : H \longrightarrow G_2 \). Denote by \( X \) the complement of \( \alpha(H) \) in \( G_1 \) and by \( Y \) the complement of \( \beta(H) \) in \( G_2 \). The group \( H \) acts on both sides on \( X \) and \( Y \) and \( X \) and \( Y \) are free \( H \)-bisets. Moreover we have:

\[ 2S_1 = R[X] \quad 1S_2 = R[Y] \quad 1S_1 = 2S_2 = 0 \]

and then:

\[ S = 2R[X]^1 \oplus 1R[Y]^2 \]

In the HNN extension case we have two monomorphisms \( \alpha : H \longrightarrow G_1 \) and \( \beta : H \longrightarrow G_1 \). Denote by \( X \) the complement of \( \alpha(H) \) in \( G_1 \) and by \( Y \) the complement of \( \beta(H) \) in \( G_1 \). Denote also by \( U \) (resp. \( V \)) the set \( G_1 \) where \( H \) acts on the left by \( \beta \) and on the right by \( \alpha \) (resp. \( H \) acts on the right by \( \beta \) and on the left by \( \alpha \)). These sets \( X, Y, U \) and \( V \) are free \( H \)-bisets. In this case, the bimodule \( S \) is characterized by the conditions:

\[ 2S_1 = R[X] \quad 1S_2 = R[Y] \quad 1S_1 = R[U] \quad 2S_2 = R[V] \]

and then:

\[ S = 2R[X]^1 \oplus 1R[Y]^2 \oplus 1R[U]^1 \oplus 2R[V]^2 \]

Consider the HNN extension case. For every \( x \in G_1 \) we set:

\[ \Gamma(x) = \beta^{-1}(x\alpha(H)x^{-1}) \quad \Gamma'(x) = \alpha^{-1}(x\beta(H)x^{-1}) \]
For each \( x \in G_1 \), \( \Gamma(x) \) and \( \Gamma'(x) \) are subgroups of \( H \) and \( \Gamma(x) \) is regular coherent. Moreover, we have a group homomorphism \( \lambda_x : \Gamma(x) \rightarrow H \) such that:

\[
\forall \gamma \in \Gamma(x), \quad \beta(\gamma) = x\alpha(\lambda_x(\gamma)) x^{-1}
\]

It is easy to see that \( \lambda_x \) is an isomorphism from \( \Gamma(x) \) to \( \Gamma'(x^{-1}) \). Thus groups \( \Gamma'(x) \) are also regular coherent.

Let:

\[
U = \biguplus_i U_i
\]

be the decomposition of \( U \) by orbits. Then, for every \( i \), there exists an element \( x \in U \) such that:

\[
U_i = \beta(H)x\alpha(H)
\]

Let \( H_1 \) (resp. \( xH \)) be the \((H, \Gamma(x))-\)biset (resp. the \((\Gamma(x), H))-\)biset) \( H \), where \( H \) acts in the standard way on the left (resp. on the right) and \( \Gamma(x) \) acts by the inclusion on the right (resp. by the morphism \( \lambda_x \) on the left). Then the map: \((u, v) \mapsto \beta(u)x\alpha(v)\) from \( H \times H \) to \( \beta(H)x\alpha(H) \) induces an isomorphism of \( H \)-bisets:

\[
H_1 \times xH \simeq \beta(H)x\alpha(H)
\]

and we have:

\[
R[U_i] \simeq R[H_1 \times xH]
\]

\[
\Rightarrow 1R[U_i]^1 \simeq 1R[H_1] \otimes_{R[H]} R[xH]^1
\]

Moreover the ring \( R[\Gamma(x)] \) is regular coherent.

Hence, because of theorem 6, we have a homotopy equivalence of spectra:

\[
\text{Nil}(C \times C, 2R[X]^1 \oplus 1R[Y]^2 \oplus 2R[V]^2) \sim \text{Nil}(C \times C, 2R[X]^1 \oplus 1R[Y]^2 \oplus 1R[U]^1 \oplus 2R[V]^2)
\]

We proceed the same with the biset \( V \) and we get a homotopy equivalence of spectra:

\[
\text{Nil}(C \times C, 2R[X]^1 \oplus 1R[Y]^2) \sim \text{Nil}(C \times C, 2R[X]^1 \oplus 1R[Y]^2 \oplus 2R[V]^2)
\]

Hence, in both amalgamated case and HNN extension case, we have a homotopy equivalence:

\[
\text{Nil}(C \times C, 2R[X]^1 \oplus 1R[Y]^2) \sim \text{Nil}(C \times C, 2R[X]^1 \oplus 1R[Y]^2 \oplus 2R[V]^2)
\]

Denote by \( Z_j \) the orbits of the biset \( X \times Y \). Then, for each \( j \), there is an element \((x, y) \in X \times Y\) such that:

\[
Z_j = \alpha(H)xy\beta(H)
\]
For each \( x \in X \) and each \( y \in Y \) we have the groups:

\[
\Gamma_1(x) = \alpha^{-1}(x\alpha(H)x^{-1}) \quad \Gamma_2(y) = \beta^{-1}(y\beta(H)y^{-1}) \quad H(x, y) = \Gamma_1(x) \cap \Gamma_2(y)
\]

We have group homomorphisms \( \lambda_x : \Gamma_1(x) \to H \) and \( \mu_y : \Gamma_2(y) \to H \) defined by:

\[
\forall \gamma \in \Gamma_1(x), \quad \alpha(\lambda_x(\gamma)) = x\alpha(\gamma)x^{-1}
\]

\[
\forall \gamma \in \Gamma_2(y), \quad \beta(\gamma) = y\beta(\mu_y(\gamma))y^{-1}
\]

Denote by \( H_x \) the \((H, H(x, y))\)-biset where \( H \) acts in the standard way on the left and \( H(x, y) \) acts via \( \lambda_x \) on the right. Denote also by \( yH \) the \((H(x, y), H)\)-biset where \( H \) acts in the standard way on the right and \( H(x, y) \) acts via \( \mu_y \) in the left. Then the map \( (u, v) \mapsto \alpha(u)xy\beta(v) \) from \( H \times H \) to \( \alpha(H)xy\beta(H) \) induces an isomorphism:

\[
H_x \times_{H(x, y)} yH \sim \to \alpha(H)xy\beta(H)
\]

where \( H(x, y) \) is regular coherent. Hence, because of theorem 6, the spectrum \( \text{Nil}(R[H], R[X \times Y]) \) is contractible and so is \( \text{Nil}(R[H] \times R[H], S) \).

\[\square\]

**4.6 Theorem:** For every group \( G \) in \( \text{Cl}_1 \) and every ring \( R \) which is regular noetherian on the right, the Whitehead spectrum \( Wh^R(G) \) is contractible.

**Proof:** Denote by \( \text{Cl}_2 \) the class of groups \( G \) such that \( Wh^R(G) \) is contractible for every ring which is regular noetherian on the right. Because of theorem 4.2, \( \text{Cl}_2 \) contains the class \( \text{Cl} \).

Since the functor \( Wh \) commutes with filtered colimits, the class \( \text{Cl}_2 \) is stable under filtered colimits. Therefore it’s enough to prove that \( \text{Cl}_2 \) is stable under taking amalgamated free products and HNN extensions of regular coherent diagrams. But that follows directly from theorems 4.3 and 4.4. \[\square\]

**4.7 Example:** Consider the group \( H \) with two generators \( x \) and \( t \) and the following relations:

\[
\forall n \in \mathbb{Z}, \quad xt^nxt^{-n} = t^nxt^{-n}x
\]

For every integer \( p \neq 0 \), the correspondence \( x \mapsto x \) and \( t \mapsto t^p \) induces a monomorphism \( f_p : H \to H \). Consider a monomorphism of groups \( \alpha : H \to G \) and denote by \( \Gamma \) the amalgamated free product of the diagram:

\[
\begin{array}{ccc}
H & \xrightarrow{f_p} & H \\
\downarrow & & \\
\alpha & & \\
G & & 
\end{array}
\]
4.8 Proposition: For every ring $R$ which is regular noetherian on the right, the morphism $G \longrightarrow \Gamma$ induces a homotopy equivalence of spectra: $\mathcal{W} h^R(G) \sim \longrightarrow \mathcal{W} h^R(\Gamma)$.

Moreover, if $G$ belongs to $\text{Cl}_1$, then the group $\Gamma$ is also in $\text{Cl}_1$.

Proof: Denote by $H'$ the normal closure of $x$ in $H$. This group is commutative and freely generated by the elements: $x_n = t^n x t^{-n}$ for $n \in \mathbb{Z}$. The correspondence $x_n \mapsto x_{n+1}$ is an automorphism $\tau: H' \sim \longrightarrow H'$ and $H$ is the semidirect product of $H'$ and $\mathbb{Z}$, or equivalently, the HNN extension of $H'$ with morphisms $\text{Id}, \tau: H' \longrightarrow H'$. On the other hand, $R[H']$ is regular coherent on the right (but not noetherian) and $H$ belongs to the class $\text{Cl}$. Hence the Whitehead spectrum $\mathcal{W} h^R(H)$ is contractible.

Denote by $H_p$ the image of $f_p: H \longrightarrow H$ and by $X$ its complement in $H$. For every $z \in H$, denote by $\Gamma(z)$ the subgroup $f_p^{-1}(z f_p(H) z^{-1})$ of $H$. We have the following formula:

$$\Gamma(f_p(a) z f_p(b)) = a \Gamma(z) a^{-1}$$

for every $a, b, z$ in $H$ and the conjugacy class of $\Gamma(z)$ depends only on the class of $z$ in the set $Y = H_p \setminus H/H_p$. Let $z$ be an element in $X$. A direct computation shows the following:

- if $z$ is congruent in $Y$ to an element in $H'$ then $\Gamma(z)$ is the group $H'$
- if $z$ is congruent in $Y$ to a power of $t$ then $\Gamma(z)$ is conjugate to the subgroup of $H$ generated by $t$
- in the other cases $\Gamma(z)$ is the trivial group.

Therefore $\Gamma(z)$ is always a free abelian group. Hence, for every $y$ in $G \setminus \alpha(H)$, the group $\Gamma(z, y) = \Gamma(z) \cap \alpha^{-1}(y \alpha(H) y^{-1})$ is also a free abelian group and the ring $R[\Gamma(z, y)]$ is regular coherent on the right. Then theorem 4.3 applies and the result follows.

\[\square\]

The class $\text{Cl}_1$ seems to be strictly bigger than the class $\text{Cl}$. For example the amalgamated free product $\Gamma$ of the diagram:

\[
\begin{array}{c}
H \xrightarrow{f_p} H \\
\downarrow f_q \\
H
\end{array}
\]

with $p, q > 1$, belongs to the class $\text{Cl}_1$. But in this case, Waldhausen’s theorems cannot be used to prove that $\Gamma$ belongs to the class $\text{Cl}$ because of the following result:

4.9 Proposition: The ring $\mathbb{Z}[H]$ is not regular coherent.

Proof: Let $f: \mathbb{Z}[H] \oplus \mathbb{Z}[H] \longrightarrow \mathbb{Z}[H]$ be the following morphism:

$$(U, V) \mapsto f(U, V) = (1 - t + tx)U - (1 - t + t^2 xt^{-1})V$$

67
and \( K \) be its kernel. We’ll prove that \( K \) is not finitely generated and that will imply that \( \mathbb{Z}[H] \) is not coherent and therefore not regular coherent.

Denote by \( A \) the ring \( \mathbb{Z}[H'] \). This ring is the ring of Laurent polynomials in the \( x_i \)'s. Then \( A \) is an integral domain and every element \( u \in \mathbb{Z}[H] \) can be written in a unique way on a finite sum:

\[
u(u) = +\infty \quad \partial^\circ u = -\infty.
\]

Define the elements \( y_i \) and \( z_i \) in \( A \) by:

\[
\forall i \in \mathbb{Z}, \quad y_i = 1 - x_i = 1 - t^ix^{-i} \quad z_i = y_i - y_{i-1} = x_{i-1} - x_i
\]

and, for every integer \( n \geq 0 \), we have the following elements in \( \mathbb{Z}[H] \):

\[
U_n = z_{-n} - t^{n+1}z_1y_{0}y_{-1} \ldots y_{-n} \\
V_n = z_{-n} + \sum_{0 \leq i \leq n} t^iz_{-n}z_1y_{0}y_{-1} \ldots y_{2-i} - t^{n+1}z_1y_{0}y_{-1} \ldots y_{1-n}y_{-1-n}
\]

An explicit computation shows that, for each \( n \geq 0 \), \( W_n = (U_n, V_n) \) is killed by \( f \) and each \( W_n \) belongs to \( K \).

4.10 Lemma: The set \( \{W_0, W_1, W_2, \ldots \} \) is a generating set of \( K \).

Proof: Denote by \( E \) the \( \mathbb{Z}[H]-\)submodule of \( \mathbb{Z}[H] \oplus \mathbb{Z}[H] \) generated by the set \( \{W_0, W_1, W_2, \ldots \} \). Since each \( W_n \) is in \( K \), we have an inclusion \( E \subset K \) and we have to prove that this inclusion is an equality.

For each integer \( n \geq 0 \), denote by \( K_n \) the set of the elements \( (U, V) \) in \( K \) satisfying the following:

\[
\nu(U) \geq 0 \quad \partial^\circ U \leq n \quad \nu(V) \geq 0 \quad \partial^\circ V \leq n
\]

We denote also by \( I_n \) the ideal \( (z_0, z_{-1}, z_{-2}, \ldots, z_{1-n}) \subset A \) and by \( J_n \) the right ideal of \( \mathbb{Z}[H] \) generated by \( I_n \).

The quotient \( B_n = A/I_n \) is the quotient of \( A \) by the relations

\[
x_0 = x_{-1} = x_{-2} = \ldots = x_{-n}
\]

and \( B_n \) is a Laurent polynomial ring where \( z_1, z_{-n} \) and all \( y_i \) are not zero.

Suppose we have proven that \( K_{n-1} \) is contained in \( E \). Let \( U = \sum_{0 \leq i \leq n} t^iu_i \) and \( V = \sum_{0 \leq i \leq n} t^iv_i \) be two elements in \( \mathbb{Z}[H] \), with \( u_i \) and \( v_i \) in \( A \). For \( W = (U, V) \) we have the following equivalences:

\[
W \in K_n \iff (1 - ty_0)U = (1 - ty_1)V
\]
\[ \iff \sum_i t^i(u_i - v_i) = ty_0 \sum_i t^i u_i - ty_1 \sum_i t^i v_i \]

\[ \iff \sum_i t^i(u_i - v_i) = \sum_i t^{i+1} y_{-i} u_i - \sum_i t^{i+1} y_{1-i} v_i \]

\[ \iff \forall i, u_i - v_i = y_{1-i} u_{i-1} - y_{2-i} v_{i-1} \]

And these conditions are equivalent to the following:

\[ v_0 = u_0 \]

\[ v_1 = u_1 + z_1 u_0 \]

\[ v_2 = u_2 + z_0 u_1 + z_1 y_0 u_0 \]

\[ \ldots \]

\[ v_n = u_n + \sum_{0 \leq i < n} z_{1-i} y_{-i} y_{-1-i-1} \ldots y_{2-n} u_i \]

\[ 0 = \sum_{0 \leq i \leq n} z_{1-i} y_{-i} y_{-1-i-1} \ldots y_{1-n} u_i \]

This last relation implies the following relation in $B_n$:

\[ z_1 y_0 y_{-1} \ldots y_{1-n} u_0 \equiv 0 \in B_n \]

and we have: $u_0 \equiv 0$ in $B_n$ because $B_n$ is an integral domain.

Suppose $W$ is in $K_n$. Then $u_0$ is in $I_n$ and there are elements $a_0, a_1, \ldots, a_{n-1}$ in $A$ such that:

\[ u_0 = z_0 a_0 + z_{-1} a_1 + \ldots + z_{1-n} a_{n-1} \]

Set:

\[ W' = W - (W_0 a_0 + W_1 a_1 + W_2 a_2 + \ldots W_{n-1} a_{n-1}) \]

Since $W_0, W_1, \ldots, W_{n-1}$ are in $K_n$, $W'$ belongs to $K_n$ and there exist elements $u_i'$ and $v_i'$ in $A$ such that:

\[ W' = \left( \sum_{0 \leq i \leq n} t^i u_i', \sum_{0 \leq i \leq n} t^i v_i' \right) \]

Moreover, because $W'$ is in $K_n$, we have $u_0' = v_0'$ and:

\[ u_0' = u_0 - (z_0 a_0 + z_{-1} a_1 + \ldots + z_{1-n} a_{n-1}) = 0 \]

So we have: $u_0' = v_0' = 0$ and $W't^{-1}$ belongs to $K_{n-1} \subset E$. Therefore $W'$ and then $W$ belong to $E$ and we have: $K_n \subset E$.

Thus $K_n$ is contained in $E$ for every $n \geq 0$. On the other hand, for every $W \in K$, there is some integer $p$ such that $Wt^p$ belongs to some $K_n$. Hence $K$ is contained in $E$ and the lemma is proven.

**4.11 Lemma:** The module $K$ is not finitely generated.
Proof: For each integer \( n > 0 \), denote by \( E_n \) the submodule of \( E \) generated by \( \{ W_0, W_1, W_2, \ldots, W_{n-1} \} \).

Let \( F_n : \mathbb{Z}[H]^n \to \mathbb{Z}[H] \oplus \mathbb{Z}[H] \) be the morphism:

\[
(c_0, c_1, c_2, \ldots, c_{n-1}) \mapsto \sum_{0 \leq i < n} W_i c_i
\]

The image of \( F_n \) is the module \( E_n \). Denote by \( R_n \) the kernel of \( F_n \) and by \( \pi_n \) the last projection \( \mathbb{Z}[H]^n \to \mathbb{Z}[H] \). We have an exact sequence of right \( \mathbb{Z}[H] \)-modules:

\[
0 \to R_n \to \mathbb{Z}[H]^n \xrightarrow{F_n} E_n \to 0
\]

Hence we have a commutative diagram of right \( \mathbb{Z}[H] \)-modules with exact lines:

\[
\begin{array}{cccccc}
0 & \longrightarrow & \mathbb{Z}[H]^{n-1} & \longrightarrow & \mathbb{Z}[H]^n & \xrightarrow{F_n} E_n & \longrightarrow & 0 \\
\downarrow F_{n-1} & & \downarrow F_n & & \downarrow & & \downarrow & \\
0 & \longrightarrow & E_{n-1} & \longrightarrow & E_n & \longrightarrow & \mathbb{Z}[H]/J'_n & \longrightarrow & 0
\end{array}
\]

with: \( J'_n = \pi_n(R_n) \). We’ll prove that \( \mathbb{Z}[H]/J'_n \) is not trivial.

An easy computation shows that, for every integers \( p, q \) with \( 0 \leq p < q \), the following element:

\[
W_q z_p - W_p z_q - W_{q-p-1} t^{p+1} z_1 y_0 y_{-1} \cdots y_{-p}
\]

is zero in \( K \) and induces a well defined element \( X(p, q) \in R_n \) (for every \( n > q \) and, for every \( p \) with \( 0 \leq p < n - 1 \), we have: \( \pi_n(X(p, n - 1)) = z_{-p} \).

Let \( n > 0 \) be an integer. Suppose \( J'_n \) is not contained in \( J_n \). Then there is an element \( X_0 \in R_n \) such that \( \pi_n(X_0) \) doesn’t belong to \( J_n \). Set: \( d = \partial^n \pi_n(X_0) \) and denote by \( Z \) the set of \( X \in R_n \) such that: \( \partial^n \pi_n(X) = d \) and \( \pi_n(X) - \pi_n(X_0) \in J_n \).

For each \( X = (c_0, c_1, \ldots, c_{n-1}) \in Z \) we can associate three integers \( \alpha, \beta, \gamma \) defined this way:

- \( \alpha = \nu(c_{n-1}) \)
- \( \beta \) is the lowest \( \nu(c_k) \), for \( k = 0, 1, \ldots, n - 1 \)
- \( \gamma \) is the highest integer \( k \) such that \( \nu(c_k) = \beta \).

The triple \( \chi(X) = (\alpha, \beta, \gamma) \) will be called the complexity of \( X \). This complexity belongs to the set \( C \) of triple \((\alpha, \beta, \gamma) \in \mathbb{Z}^3 \) satisfying the following conditions:

\[
\beta \leq \alpha \leq d \quad \text{and} \quad 0 \leq \gamma < n
\]

The lexicographical order of \((d - \alpha, \alpha - \beta, \gamma)\) induces a well order relation on \( C \) and we have:

\[
(\alpha, \beta, \gamma) < (\alpha', \beta', \gamma') \iff \alpha > \alpha' \text{ or } \alpha = \alpha' \text{ and } \beta > \beta' \text{ or } (\alpha, \beta) = (\alpha', \beta') \text{ and } \gamma < \gamma'
\]
Since $C$ is well ordered, there is an element in $Z$ with a minimal complexity. Let $X = (c_0, c_1, \ldots, c_{n-1})$ be such an element.

For each integer $k \in \{0, 1, \ldots, n-1\}$, we have a decomposition:

$$c_k = \sum_{\beta \leq i} c_{ki} t^i$$

with $c_{ki} \in A$.

The condition $X \in R_n$ implies the following:

$$\sum_{0 \leq k \leq \gamma} z_{-k} c_{k\beta} = 0$$

and that implies the congruence $z_{-\gamma} c_{\gamma\beta} \equiv 0$ in $B_\gamma = A/I_\gamma$. But $z_{-\gamma}$ is not a zero divisor in $B_\gamma$ and $c_{\gamma\beta}$ belongs to $I_\gamma$. So we have a decomposition in $A$:

$$c_{\gamma\beta} = \sum_{0 \leq j < \gamma} z_{-j} a_j$$

and we get a new element in $R_n$:

$$X' = X - \sum_{0 \leq j < \gamma} X(j, \gamma) a_j t^\beta$$

It is easy to see that $\pi_n(X') \equiv \pi_n(X) \equiv \pi_n(C_0) \mod J_n$ and that $X'$ belongs to $Z$. Moreover we have the following: $\chi(X') < \chi(X)$. But that’s impossible because $X$ was chosen with a minimal complexity.

Hence we get a contradiction and the module $J'_n$ is contained in $J_n$. As a consequence, by killing all the $z_i$’s, we get epimorphisms:

$$Z[H]/J'_n \longrightarrow Z[H]/J_n \longrightarrow Z[x^\pm 1, t^\pm 1]$$

and $Z[H]/J'_n$ is not trivial. Hence the sequence $E_0 \subset E_1 \subset E_2 \subset \ldots$ is strictly increasing and $E = \text{Ker}(f)$ is not finitely generated. Therefore the category of finitely presented right $Z[H]$-modules is not abelian and $Z[H]$ is not coherent. The result follows.
