Stability Within $T^2$-Symmetric Expanding Spacetimes

Beverly K. Berger, James Isenberg and Adam Layne

Abstract. We prove a nonpolarised analogue of the asymptotic characterisation of $T^2$-symmetric Einstein flow solutions completed recently by LeFloch and Smulevici. In this work, we impose a condition weaker than polarisation and so our result applies to a larger class. We obtain similar rates of decay for the normalised energy and associated quantities for this class. We describe numerical simulations which indicate that there is a locally attractive set for $T^2$-symmetric solutions not covered by our main theorem. This local attractor is distinct from the local attractor in our main theorem, thereby indicating that the polarised asymptotics are unstable.

1. Introduction

There exist broad conjectures about the expanding direction behaviour of vacuum spacetimes with closed Cauchy surfaces [2,7], but currently little is known about some of the most elementary examples. Recent results [13,17] have demonstrated that certain vacuum cosmological models demonstrate locally stable behaviour in the expanding direction, but that well-known subclasses are unstable.

In the special case that the spacetime has spatial topology $T^3$ admits two spacelike Killing vector fields (such spacetimes are called $T^2$-symmetric) and satisfies a further technical condition (that the spacetime is polarised); results of [13] show that there is a local attractor of the Einstein flow in the expanding direction. It is natural to ask whether the condition that the spacetime be polarised is necessary. Do spacetimes on $T^3$ with two spacelike Killing vector fields necessarily become effectively polarised? Do they then flow to the polarised attractor?

We partially resolve these questions by analytic and numerical means. Our main theorem states that solutions which are not polarised have the
expanding direction asymptotics of polarised solutions if they satisfy a certain weaker condition: that one of the two conserved quantities of the flow vanishes. We call such solutions $B_0$ or $B = 0$ solutions. The conserved quantity $B$ vanishes for all polarised solutions; the set of $B = 0$ solutions is of codimension one in the space of all solutions in these coordinates while the set of polarised solutions is of infinite codimension.

It was shown in [5] that $T^2$-symmetric vacuum spacetimes possess a global foliation; all such Einstein flows have a metric of the form

$$
g = e^{-V+4\tau} \left[ -d\tau^2 + e^{2(\rho-\tau)} d\theta^2 \right] + e^V \left[ dx + Qdy + (G + QH)d\theta \right]^2 + e^{-V+2\tau} \left[ dy + Hd\theta \right]^2 \tag{1.1}$$

where $\partial_x$ and $\partial_y$ are the Killing vector fields. The area of the $\{\partial_x, \partial_y\}$ orbit is $e^{2\tau}$, so the singularity occurs as $\tau \to -\infty$ and the spacetime expands as $\tau \to \infty$. Roughly, $Q$ measures the angle between the Killing vector fields and $V$ measures the ratio of lengths of integral curves in the two Killing directions.

Relative to the coordinates $t, P, \alpha, \lambda$ used in [17], our quantities are given by

$$\tau := \log t, \quad \rho := -\frac{1}{2} \log \alpha \quad \quad V := P + \log t, \quad \hat{l} := P + \frac{1}{2} \lambda - \frac{3}{2} \log t.$$ 

See the “Appendix” for a complete concordance of notations between the cited papers and the present work. In the coordinates (1.1), the Einstein flow is

$$\partial_\tau (e^\rho V_\tau) = \partial_\theta \left( e^{2(\tau-\rho)} V_\theta \right) + e^{2(V-\tau)+\rho} \left( Q_\tau^2 - e^{2(\tau-\rho)} Q_\theta^2 \right) \tag{1.2}$$

$$\partial_\tau \left( e^{\rho+2(V-\tau)} Q_\tau \right) = \partial_\theta \left( e^{-\rho+2V} Q_\theta \right) \tag{1.3}$$

$$\hat{l}_\tau + \rho_\tau + 2 = \frac{1}{2} \left[ V_\tau^2 + e^{2(\tau-\rho)} V_\theta^2 + e^{2(V-\tau)} \left( Q_\tau^2 + e^{2(\tau-\rho)} Q_\theta^2 \right) \right] \tag{1.4}$$

$$\rho_\tau = K^2 e^{\hat{l}} \tag{1.5}$$

$$\hat{l}_\theta = V_\theta V_\tau + e^{2(V-\tau)} Q_\theta Q_\tau. \tag{1.6}$$

The last equation is the momentum constraint, and it is preserved by the evolution equations. Equation (1.5) is a consequence of the constraints; $\rho$ satisfies a wave equation similar to (1.2) which can be derived as a consequence of (1.4) and (1.5), so we take Eqs. (1.2) through (1.5) to be the evolution equations instead. There are, in addition, evolution equations for $G, H$, but these may be integrated once $V, Q, \rho, \hat{l}$ have been found, so these latter four functions are the ones of interest. As a consequence of (1.2) and (1.3), there are two conserved quantities along the flow:

$$A := \int_{S^1} e^\rho \left( V_\tau - e^{2(V-\tau)} Q_\tau Q \right) d\theta$$

$$B := \int_{S^1} e^{\rho+2(V-\tau)} Q_\tau d\theta.$$
The constant $K$ is, without loss of generality, that “twist constant” which cannot in general be made to vanish by a coordinate transformation. The condition $Q \equiv 0$ is often imposed when studying these solutions in the collapsing direction. Such solutions are called polarised.\(^1\) (Note that all polarised solutions have $B = 0$, but not all $B = 0$ solutions are polarised.) The $T^3$ Gowdy models \([9]\) are those for which $K = 0$.

$T^2$-symmetric spacetimes which are polarised or Gowdy have been studied extensively in the contracting direction (e.g., \([1]\)). We are here concerned only with the expanding direction.

The Kasner models are those which are spatially homogeneous ($\tilde{l}, V, Q$ are independent of $\theta$) and satisfy $K = 0$. Let us note that, in our coordinates, polarised Kasner solutions \([12]\) take the form

$$V = a\tau + b, \quad \tilde{l} = \left(\frac{1}{2} a^2 - 2\right) \tau + c$$

for some constants $a, b, c \in \mathbb{R}$. The Gowdy models contain all Kasners, and in the expanding direction the dynamics of Gowdy solutions are known \([16, 18]\) and appear to be very different from those of non-Gowdy solutions. Non-Gowdy solutions such that $\tilde{l}, V, Q$ are independent of $\theta$ are called pseudo-homogeneous or PH. This definition appears in \([17]\), where it is shown that the

\(^1\) Let us note how the other twist constant is forced to vanish. Suppose $X, Y$ are Killing vector fields. The twist constants are defined by

$$K(X) := \varepsilon_{ijkl} X^i Y^j (\nabla X)^{kl}, \quad K(Y) := \varepsilon_{ijkl} X^i Y^j (\nabla Y)^{kl}$$

where $\varepsilon$ is the volume form written as a tensor (sometimes called the Levi-Civita tensor) \([9]\). It is a consequence of the vacuum Einstein field equations and Killing’s equation that these two quantities are spacetime constants \([8]\). To obtain a pair of global, spacelike, Killing vector fields $\tilde{X}, \tilde{Y}$ with the same span as \{$X, Y$\} one must perform a linear transformation

$$\begin{pmatrix} \tilde{X} \\ \tilde{Y} \end{pmatrix} = A \begin{pmatrix} X \\ Y \end{pmatrix},$$

for some constant $A \in GL(2)$ (more general coordinate transformations do not produce Killing vector fields). A purely algebraic computation reveals that the twist constants transform by

$$\begin{pmatrix} K(\tilde{X}) \\ K(\tilde{Y}) \end{pmatrix} = (\det A) A \begin{pmatrix} K(X) \\ K(Y) \end{pmatrix}.$$ 

It is straightforward to see that at most one of the twists may be made to vanish (in fact one can find $A \in SO(2)$ accomplishing this).

Suppose we have performed such a transformation so that $K(X) = 0$. Then due to \([5]\) we may write the metric in the form (1.1). If $Q$ is constant, one could take $\tilde{x} = x + Qy$, $\tilde{y} = y$ to force $Q$ to vanish in the new coordinates. One can compute using the formula above that $K(\partial_{\tilde{x}})$ vanishes. Thus one could instead define polarisation for such models to be the existence of a pair of independent, global, spacelike Killing vector fields $X, Y$ such that $g(\partial_{\tilde{x}}, \partial_{\tilde{y}})$ is constant. The above discussion shows that this geometric definition gives the same set as $g(X, Y) \equiv 0$ up to coordinate change. Recall that in our coordinates (1.1), $\partial_x, \partial_y$ are Killing and $g(\partial_x, \partial_y) = e^V Q = Qg(\partial_x, \partial_x)$.

We are thankful to the reviewer for encouraging us to elaborate on these issues.
future asymptotics are of the form

$$|V - (a\tau + b)| \to 0, \quad |\hat{\ell} - \left(\frac{1}{2}a^2 - 2\right)\tau + c| \to 0, \quad a \in (-2, 2).$$

That is, PH solutions have asymptotics of the same form as a Kasner solution, but the value of $V_\tau$ at $\tau = \infty$ is restricted.

In contrast to these examples, in [13] the authors find a set of non-Gowdy, polarised solutions such that

$$|V - b| \to 0, \quad |\hat{\ell} - c| \to 0.$$  \hfill (1.7)

The results in [13,17] are much more detailed than the above statements; we give this simple description only to demonstrate that an instability arises; no polarised Kasner or PH solutions can have future behaviour of the form (1.7). The relationships between these sets of solutions are given in Fig. 1.

Previous to this work, numerical simulations conducted by Berger [3,4] indicated that all $T^2$-symmetric solutions, without regard to the polarisation or smallness conditions imposed in [13], flowed towards the polarised attractor (1.7). In addition, in [17] it is shown that within the neighbourhood of each polarised PH solution is a polarised non-PH solution with future asymptotics of the form (1.7).

Before giving a description of our main theorem, let us note the sense in which we use the word “attractor”. Our technique of proof follows [13]. Let us denote the right side of (1.4) by $J$. The idea of the proof is to treat the asymptotic regime of the solution as a wave equation for $V, Q$ coupled to an ordinary differential equation (up to some error terms) for the means in the $\theta$-direction of $e^\rho, e^\hat{\ell}, J$. The smallness assumptions are then used to guarantee that the errors decay and so the behaviour of the means of $e^\rho, e^\hat{\ell}, J$ approaches the behaviour of the solution of the ODE. When we use the word “attractor” here, we refer to the dynamics of the $e^\rho, e^\hat{\ell}, J$ system; a solution $V', Q', \rho', \hat{\ell}'$ is not generally a proper attractor of the flow in the sense that

$$\|V - V'\| + \|Q - Q'\| + \|\rho - \rho'\| + \|\hat{\ell} - \hat{\ell}'\| \to 0$$

in $C^k$ norm.
Our main theorem states roughly that the condition $B = 0$ suffices to ensure that a solution has polarised asymptotics if it begins sufficiently close to the asymptotic regime. In the latter portion of the paper, we present numerical evidence that the condition $B = 0$ is necessary for the solution to have polarised asymptotics and flow towards the polarised attractor. There appears to be an attractor for solutions satisfying $B \neq 0$, which shares some formal properties with the $B = 0$ attractor. However, such solutions flow away from the $B = 0$ attractor, and so the $B = 0$ asymptotics appear to be unstable.

Our proof technique is essentially a refinement of the technique used in [13] for the polarised case. We use a different correction which allows us to deal with terms coming from $Q$. Most essentially, however, while the term $\int_{S^1} e^\rho V_\tau \, d\theta$ is conserved by the flow in the polarised case it is not preserved in the nonpolarised case. This quantity arises naturally in several key places in the proof. The condition $B = 0$ guarantees that this term is $O(1)$ which allows us to deal with the new error terms. In Sect. 8, we present evidence that this condition is also necessary; if $B \neq 0$ the quantity $\int_{S^1} e^\rho V_\tau \, d\theta$ does not appear to be bounded.

Since the future behaviour of Gowdy and PH solutions is understood, we are only concerned with non-Gowdy, non-PH solutions; that is, solutions with $K \neq 0$ and $\int_{S^1} e^\rho \, d\theta$ unbounded as $\tau \to \infty$. In this case, we shift $\hat{l}$ by a constant

$$l := \hat{l} + \log(K^2)$$

so that

$$\hat{l}_\theta = l_\theta, \quad \hat{l}_\tau = l_\tau \quad \text{and} \quad \rho_\tau = e^l.$$

In the rest of the paper, we assume solutions are non-Gowdy and so change variables to $l$ to avoid writing factors of $K$.

Before proceeding with the proof, it is important to note that there is some very interesting work on the rescaling limits of certain expanding spacetimes [10,11,14,15]. The earlier of these works uses techniques from the study of Ricci Flow to analyse the rescaling limits of CMC-foliated expanding spacetimes. The latter three are concerned with the extent to which rescaling limits of spacetimes (including those considered in [13]) have a nonzero Einstein tensor. It is likely that these results can be generalised to the class of solutions considered in this paper.

### 2. Preliminary Computations

Before proceeding with the proof of the main theorem, we define the energy under consideration and calculate its evolution. It is useful to have notation for the mean of a function in the $\theta$-direction.

**Definition 2.1** ($S^1$-mean). For $f : S^1 \to \mathbb{R}$, let

$$\langle f \rangle := \int_{S^1} f(\theta) \, d\theta.$$
Note that in [13], the authors choose to use the volume form $e^\rho \, d\theta$ for their mean. Our choice is almost identical to that used in [17], but we normalise so that $\int_{S^1} d\theta = 1$. Either choice would suffice.

Define the following energy
\[
J := \frac{1}{2} \left[ V^2 + e^{2(\tau - \rho)} V_\theta^2 + e^{2(V - \tau)} \left( Q^2 + e^{2(\tau - \rho)} Q_\theta^2 \right) \right],
\]
\[
E := \int_{S^1} e^{\rho - 2\tau} J \, d\theta
= \frac{1}{2} \int_{S^1} e^{\rho - 2\tau} V^2 + e^{-\rho} V_\theta^2 + e^{2V - 4\tau + \rho} Q^2 + e^{2(V - \tau) - \rho} Q_\theta^2 \, d\theta,
\]
and the $S^1$-volume
\[
\Pi := \langle e^\rho \rangle = \int_{S^1} e^\rho \, d\theta.
\]

Note that Eq. (1.4) now reads $l_\tau + \rho_\tau + 2 = J$. We use the terms $V$-energy and $Q$-energy loosely to refer to $V^2 + e^{2(\tau - \rho)} V_\theta^2$ and $e^{2(V - \tau)} \left( Q^2 + e^{2(\tau - \rho)} Q_\theta^2 \right)$, respectively. One may compute using the evolution equations for $V$ and $Q$ that
\[
\partial_\tau (e^\rho J) = 2e^\rho J - \rho_\tau e^\rho J - e^\rho V^2 - e^{2V - \rho} Q^2_\theta + \partial_\theta \left( e^{2\tau - \rho} V_\theta V_\tau + e^{2V - \rho} Q_\theta Q_\tau \right)
\]
so the energy $E$ evolves by
\[
E_\tau = \int_{S^1} -\rho_\tau e^{\rho - 2\tau} J - e^{\rho - 2\tau} V^2_\tau - e^{2(V - \tau) - \rho} Q^2_\theta \, d\theta.
\]
The terms $-e^{\rho - 2\tau} V^2_\tau - e^{2(V - \tau) - \rho} Q^2_\theta$ appearing here are undesirable for proving energy inequalities. This necessitates the modification of $E$ by a term which trades $V^2_\tau$ for $V^2_\theta$. This is the main topic of Sect. 3.

3. Corrections and Their Bounds

Define the correction
\[
\Lambda := \frac{1}{2} e^{-2\tau} \int_{S^1} V_\tau (V - \langle V \rangle - 1) \, e^\rho \, d\theta. \tag{3.1}
\]
Corrections to the energy of essentially this form were used previously in the Gowdy case [16] and in the existing results on $T^2$-symmetric spacetimes [13,17]. Our definition differs only slightly from those previously used. Differentiating (3.1) and using integration by parts yields the two components of the $V$-energy, but with opposite sign. This allows us to replace time derivatives by space derivatives, which may be bounded. At the same time, the correction has better decay properties than the energy, and so we are able to draw conclusions about the energy in the expanding direction.

To trade $V^2_\tau$ for $V^2_\theta$ and $Q^2_\tau$ for $Q^2_\theta$, it would be more natural to consider the corrections
\[
\frac{1}{2} e^{-2\tau} \int_{S^1} V_\tau (V - \langle V \rangle) \, e^\rho \, d\theta, \quad \text{and} \quad \frac{1}{2} e^{-2\tau} \int_{S^1} e^{2(V - \tau)} Q_\tau (Q - \langle Q \rangle) \, e^\rho \, d\theta
\]
separately as other authors have done. Then, by differentiating the $Q$-correction one would hope to obtain terms of the form $Q^{2}_{\tau} - e^{2(\tau - \rho)}Q^{2}_{\theta}$, perhaps with a leading factor. Our definition exploits the fact that (1.2) contains exactly the expression that we would like to obtain from the $Q$-correction.

**Lemma 3.1.** Consider a non-Gowdy $T^{2}$-symmetric Einstein flow. The correction defined in (3.1) evolves by

$$\partial_{\tau} \Lambda = -2\Lambda - \frac{1}{2} \langle e^{-\rho}V^{2}_{\theta} \rangle + \frac{1}{2} \langle e^{\rho - 2\tau}V^{2}_{\tau} \rangle - \frac{1}{2} \langle V_{\tau} \rangle \langle e^{\rho - 2\tau}V_{\tau} \rangle$$

$$+ \frac{1}{2} e^{-2\tau} \int_{S^{1}} e^{2(V - \tau) + \rho} \left( Q^{2}_{\tau} - e^{2(\tau - \rho)}Q^{2}_{\theta} \right) (V - \langle V \rangle - 1) \, d\theta.$$  

**Proof.** We compute straightforwardly using Eqs. (1.2), (1.3) and integration by parts. From the definition of $\Lambda$, we have

$$\partial_{\tau} \Lambda = -2\Lambda + \frac{1}{2} e^{-2\tau} \int_{S^{1}} (e^{\rho}V_{\tau})_{\tau} (V - \langle V \rangle - 1) \, d\theta$$

$$+ \frac{1}{2} e^{-2\tau} \int_{S^{1}} V_{\tau} \partial_{\tau} (V - \langle V \rangle - 1) e^{\rho} \, d\theta$$

$$= -2\Lambda + \frac{1}{2} e^{-2\tau} \int_{S^{1}} \left[ e^{2\tau} (e^{-\rho}V_{\theta})_{\theta} + e^{2(V - \tau) + \rho} \left( Q^{2}_{\tau} - e^{2(\tau - \rho)}Q^{2}_{\theta} \right) \right]$$

$$\times (V - \langle V \rangle - 1) \, d\theta + \frac{1}{2} e^{-2\tau} \int_{S^{1}} V_{\tau} \partial_{\tau} (V - \langle V \rangle - 1) e^{\rho} \, d\theta$$

$$= -2\Lambda + \frac{1}{2} e^{-2\tau} \int_{S^{1}} e^{-2\tau} e^{-\rho}V^{2}_{\theta} \, d\theta + \frac{1}{2} e^{-2\tau} \int_{S^{1}} V^{2}_{\tau} e^{\rho} \, d\theta$$

$$+ \frac{1}{2} e^{-2\tau} \int_{S^{1}} e^{2(V - \tau) + \rho} \left( Q^{2}_{\tau} - e^{2(\tau - \rho)}Q^{2}_{\theta} \right) (V - \langle V \rangle - 1) \, d\theta$$

$$- \langle V_{\tau} \rangle \langle \frac{1}{2} e^{\rho - 2\tau}V_{\tau} \rangle$$

which completes the proof. \qed

We modify the energy $E$ by $\Lambda$. It is then desirable to know that $\Lambda$ has better decay than $E$. To that end, note that

$$\|V - \langle V\rangle\|_{C^{0}} \lesssim \int_{S^{1}} |V_{\theta}| \, d\theta \leq \left( \int_{S^{1}} V^{2}_{\theta} e^{-\rho} \, d\theta \right)^{1/2} \Pi^{1/2} \leq (\Pi E)^{1/2}. \quad (3.2)$$

As is standard (cf. [19]), we use the notation $f \lesssim h$ to mean that there is a universal constant $C > 0$ such that $f \leq Ch$.

One finds the following bound using Hölder’s Inequality.

**Lemma 3.2** ([17], Lemma 72). Consider a non-Gowdy $T^{2}$-symmetric Einstein flow. Then

$$\left| \Lambda + \left\langle \frac{1}{2} e^{\rho - 2\tau}V_{\tau} \right\rangle \right| = \left| \frac{1}{2} e^{-2\tau} \int_{S^{1}} V_{\tau} (V - \langle V \rangle) e^{\rho} \, d\theta \right| \lesssim e^{-\tau} \Pi E \quad (3.3)$$

For the following bound on the $Q$ correction, cf. [17] Lemma 73, where the author assumes a uniform bound on $\Pi$ which we don’t assume here. The proof is essentially the same.
Lemma 3.3. For any a non-Gowdy $T^2$-symmetric Einstein flow,

$$\left| e^{-2\tau} \int_{S^1} e^{2(V-\tau)} Q_{\tau} (Q - \langle Q \rangle) e^\rho \, d\theta \right| \lesssim e^{-\tau} e^{2(\Pi E)^{1/2}} \Pi E$$

Note that we have already bounded $\| V - \langle V \rangle \|_{C^0}$ in equation (3.2), and so we may commute out factors of $e^V$ to obtain

$$e^V (Q - \langle Q \rangle) \leq e^{2V} (\int_{S^1} e^{2V} Q_0^2 e^{-\rho} \, d\theta)^{1/2} \Pi^{1/2} \leq e^{2\| V - \langle V \rangle \|_{C^0} \tau (E \Pi)^{1/2}}$$

via Hölder’s inequality. So we may compute, using the bound on $\| V - \langle V \rangle \|_{C^0}$, Hölder’s inequality, and the definition of $E$

$$\left| e^{-2\tau} \int_{S^1} e^{2(V-\tau)} Q_{\tau} (Q - \langle Q \rangle) e^\rho \, d\theta \right| \leq e^{-4\tau} e^{V} (Q - \langle Q \rangle) \left( \int_{S^1} e^{2V} Q_0^2 e^{-\rho} \, d\theta \right)^{1/2} \Pi^{1/2} \leq e^{2\| V - \langle V \rangle \|_{C^0} \tau (E \Pi)^{1/2}}$$

We only need the $Q$ correction for the following identity, which follows directly from the definitions of the conserved quantities $A, B$:

$$\langle e^\rho V_\tau \rangle = A + B \langle Q \rangle + \int_{S^1} e^{2(V-\tau)} Q_{\tau} (Q - \langle Q \rangle) e^\rho \, d\theta.$$ (3.4)

For $B_0$ solutions, however, we use the bound on the $Q$ correction to obtain the following bound

$$\left| \langle e^{\rho-2\tau} V_\tau \rangle \right| - e^{-2\tau} |A| \lesssim e^{-\tau} e^{2(\Pi E)^{1/2}} \Pi E$$ (3.5)

which together with (3.3) yields the desired estimate on the correction.

Proposition 3.4. For any a non-Gowdy, $B_0$ $T^2$-symmetric Einstein flow,

$$|\Lambda| - e^{-2\tau} |A| \lesssim e^{-\tau} \left( 1 + e^{2(\Pi E)^{1/2}} \right) \Pi E.$$ (3.6)

The correction $\Lambda$ introduces significant new error terms after differentiation. However, these terms have good bounds, and the modified energy $E + \Lambda$ has significantly better properties upon comparison to $E$ alone. The evolution of this modified energy is the focus of the next section.
4. The Corrected Energy

One would like to show that, up to error terms, $\Pi$ and $E$ satisfy an ODE. While this is true asymptotically, it is more useful to compute with an energy which has been modified by the correction.

One computes that

\[
\begin{align*}
(E + \Lambda)_\tau &= \int_{S^1} -e^{\rho-2\tau} \rho J - e^{\rho-2\tau} V^2 - e^{2(V-\tau)-\rho} Q^2 d\theta - 2\Lambda \\
&\quad + \frac{1}{2} e^{-2\tau} \int_{S^1} -e^{2\tau} e^{-\rho} V^2 d\theta + \frac{1}{2} e^{-2\tau} \int_{S^1} V^2 e^\rho d\theta \\
&\quad + \frac{1}{2} e^{-2\tau} \int_{S^1} e^{2(V-\tau)+\rho} \left( Q^2 - e^{2(\tau-\rho)} Q^2 \right) (V - \langle V \rangle) \ d\theta \\
&\quad - \langle V_\tau \rangle \left( \frac{1}{2} e^{\rho-2\tau} V_\tau \right) \\
&= - \left( 1 + \frac{\Pi_\tau}{\Pi} \right) (E + \Lambda) + \left( \frac{\Pi_\tau}{\Pi} E - \int_{S^1} e^{\rho-2\tau} \rho J d\theta \right) \\
&\quad - \left( 1 - \frac{\Pi_\tau}{\Pi} \right) \Lambda \\
&\quad + \frac{1}{2} e^{-2\tau} \int_{S^1} e^{2(V-\tau)+\rho} \left( Q^2 - e^{2(\tau-\rho)} Q^2 \right) (V - \langle V \rangle) \ d\theta \\
&\quad - \langle V_\tau \rangle \left( \frac{1}{2} e^{\rho-2\tau} V_\tau \right). 
\end{align*}
\]

The leading term on the right leads us to the ansatz that $\Pi (E + \Lambda)$ (and so $\Pi E$) should decay like $e^{-\tau}$. Accordingly, define the corrected, normalised energy $H := \Pi (E + \Lambda)$. One computes that

\[
\partial_\tau (e^\tau H) = e^\tau H + e^\tau \Pi_\tau (E + \Lambda) + e^\tau \Pi (E + \Lambda)_\tau \\
= e^\tau \Pi \left( (E + \Lambda) \left( 1 + \frac{\Pi_\tau}{\Pi} \right) + (E + \Lambda)_\tau \right) \\
= e^\tau \Pi \left[ \left( \frac{\Pi_\tau}{\Pi} E - \int_{S^1} e^{\rho-2\tau} \rho J d\theta \right) - \left( 1 - \frac{\Pi_\tau}{\Pi} \right) \Lambda \\
+ \frac{1}{2} e^{-2\tau} \int_{S^1} e^{2(V-\tau)+\rho} \left( Q^2 - e^{2(\tau-\rho)} Q^2 \right) (V - \langle V \rangle) \ d\theta \\
- \langle V_\tau \rangle \left( \frac{1}{2} e^{\rho-2\tau} V_\tau \right) \right]. 
\]

The ansatz in the local stability proof is that $e^\tau H$ is of constant order. The proof is via a bootstrap argument, where we bound all of the terms of $\partial_\tau (e^\tau H)$ in terms of $\Pi, E, H$ and $\tau$. The following Proposition deals with each of these error terms.

**Proposition 4.1.** Consider the evolution of a $B_0$ solution with initial data given at time $\tau = s_0$. Let $\rho_0 := \min_{\theta \in S^1} \rho(\theta, s_0)$. The following estimates hold for $\tau \geq s_0$. 
\[ \frac{\Pi}{\Pi} E - \int_{S^1} e^{\rho - 2\tau} \rho \tau J \, d\theta \leq E \int_{S^1} e^{\rho - \tau} \rho \tau J \, d\theta, \tag{4.2} \]

\[ \left| 1 - \frac{\Pi}{\Pi} \right| \Lambda \lesssim |A| e^{-2\tau} \left( 1 + \frac{\Pi}{\Pi} \right) + e^{-\tau} \left( 1 + e^{2(\Pi E)^{1/2}} \right) (\Pi + \Pi) E, \tag{4.3} \]

\[ \langle V, \frac{1}{2} e^{\rho - 2\tau} V \rangle \lesssim e^{-\rho_0/2} e^{-\tau} \left( |A| + e^\tau e^{2(\Pi E)^{1/2}} \Pi E \right) E^{1/2}, \tag{4.4} \]

and

\[ e^{-2\tau} \int_{S^1} e^{2(V - \tau) + \rho} \left( Q^2_\tau - e^{2(\tau - \rho)} Q^2_\theta \right) (V - \langle V \rangle) \, d\theta \lesssim \Pi^{1/2} E^{3/2}. \tag{4.5} \]

**Proof.** For (4.2), using Young’s inequality, we note that

\[ |l_0| \leq |V_\tau V_\theta| e^{V - \tau} Q_\tau e^{V - \tau} Q_\theta | = |e^{\rho - \tau} V_\tau e^{-(\rho - \tau)/2} V_\theta| + |e^{\rho - \tau} e^{(\rho - \tau)/2} Q_\tau e^{\tau - \rho/2} Q_\theta| \]

\[ \leq \frac{1}{2} \left[ e^{\rho - \tau} V^2_\tau + e^{\tau - \rho} V^2_\theta + e^{2(V - \tau)} e^{\rho - \tau} Q^2_\tau + e^{2(V - \tau)} e^{\rho - \tau} Q^2_\theta \right] = e^{\rho - \tau} J. \tag{4.6} \]

Thus we may use the Poincaré inequality to compute that

\[ \left| \frac{\Pi}{\Pi} E - \int_{S^1} e^{\rho - 2\tau} \rho \tau J \, d\theta \right| \]

\[ = \Pi^{-1} \left| \Pi_\tau E - \Pi \int_{S^1} e^{\rho - 2\tau} \rho \tau J \, d\theta \right| \]

\[ = \Pi^{-1} \left| \int_{S^1} \int_{S^1} e^{\rho(\phi) - \rho(\theta)} e^{2\tau} J(\theta) \left( \rho_\tau(\phi) - \rho_\tau(\theta) \right) \, d\phi \, d\theta \right| \]

\[ \leq \Pi^{-1} \left| \int_{S^1} \int_{S^1} e^{\rho(\phi) - \rho(\theta)} e^{2\tau} J(\theta) \sup_{a, b \in S^1} |\rho_\tau(a) - \rho_\tau(b)| \, d\phi \, d\theta \right| \]

\[ = \Pi^{-1} \int_{S^1} e^{\rho(\theta) - 2\tau} J(\theta) \, d\theta \sup_{a, b \in S^1} |\rho_\tau(a) - \rho_\tau(b)| \]

\[ \lesssim E \int_{S^1} \rho_\tau |l_0| \, d\theta \]

\[ \leq E \int_{S^1} \rho_\tau e^{\rho - \tau} J \, d\theta. \]

Inequality (4.3) follows directly from inequality (3.6). To prove (4.5), we first commute out the \( V \)-mean.

\[ e^{-2\tau} \int_{S^1} e^{2(V - \tau) + \rho} \left( Q^2_\tau - e^{2(\tau - \rho)} Q^2_\theta \right) (V - \langle V \rangle) \, d\theta \]

\[ \leq e^{-2\tau} \left\| V - \langle V \rangle \right\|_{C^0} \left| \int_{S^1} e^{2(V - \tau) + \rho} \left| Q^2_\tau - e^{2(\tau - \rho)} Q^2_\theta \right| \, d\theta \right| \]

\[ \lesssim e^{-2\tau} (\Pi E)^{1/2} \left| \int_{S^1} e^\rho e^{2(V - \tau)} \left( Q^2_\tau + e^{2(\tau - \rho)} Q^2_\theta \right) \, d\theta \right| \]
\[
\lesssim (\Pi E)^{1/2} \int_{S^1} e^{\rho - 2\tau} J \, d\theta \\
= \Pi^{1/2} E^{3/2}.
\]

Lastly, for (4.4) recall that \( \rho \) is increasing and compute that
\[
|\langle V_\tau \rangle| \leq \left( \int_{S^1} V^2_\tau e^\rho \, d\theta \right)^{1/2} \left( \int_{S^1} e^{-\rho} \, d\theta \right)^{1/2} \\
\leq e^{-\rho_0/2} e^\tau \left( \int_{S^1} V^2_\tau e^{\rho_0 - 2\tau} \, d\theta \right)^{1/2} \lesssim e^{-\rho_0/2} e^\tau E^{1/2}
\]
and use (3.5). This completes the proof. \( \square \)

Now that we have an energy satisfying a good differential equation with good bounds on the error, we proceed to the linearisation.

5. Linearisation

In [13], the authors present an argument that certain asymptotic rates of \( \Pi, E \) should be preferred, based on the assumption that \( e^\tau H \) should be of constant order. In this section, we briefly summarise that argument as it appears in our context.

**Definition 5.1.** Let \( Y := \langle e^{l+\rho+2\tau} \rangle \).

This quantity has been previously considered; see [6] where (modulo factors of \( e^\tau \)) it is called the “twist potential”.

Note that we have defined \( Y \) so that \( Y_\tau = \langle e^{l+\rho+2\tau}(l_\tau + \rho_\tau + 2) \rangle = \langle e^{l+\rho+2\tau} J \rangle \). We want to form a system of ordinary differential equations from the means, however. So we distribute the integral over the product, introducing the error term \( \Omega \). One computes

\[
\Pi_\tau = e^{-2\tau} Y \tag{5.1}
\]
\[
Y_\tau = e^{2\tau} EY \Pi^{-1} + \Omega \tag{5.2}
\]

where

\[
\Omega := \langle e^{l+\rho+2\tau} J \rangle - e^{2\tau} EY \Pi^{-1}
\]
is an error term satisfying
\[
|\Omega| \leq e^{4\tau} E \langle e^{l+\rho-\tau} J \rangle = e^\tau EY_\tau.
\]

Note that our quantity \( E \) contains the terms \( Q_\theta \) and \( Q_\tau \), and so is not identical to the energy in [13]. Nonetheless, the quantities \( \Pi, Y, E \) satisfy similar relations to the relations that LeFloch and Smulevici’s quantities do. Normalising, we compute that
\[
\partial_\tau \left( e^{-\tau} H^{-1/2} \Pi \right) = e^{-\tau} H^{-1/2} \Pi_\tau - e^{-\tau} H^{-1/2} \Pi - \frac{1}{2} e^{-\tau} H^{-1/2} \Pi \frac{H_\tau}{H} \\
= \left( e^{-3\tau} H^{-1/2} Y \right) + \left( e^{-\tau} H^{-1/2} \Pi \right) \left( -1 - \frac{1}{2} \frac{H_\tau}{H} \right)
\]
\[ \partial_\tau \left( e^{-3\tau H^{-1/2}Y} \right) = e^{-3\tau H^{-1/2}Y} - 3e^{-3\tau H^{-1/2}Y} - \frac{1}{2} e^{-3\tau H^{-1/2}Y} \frac{H_\tau}{H} \]
\[ = e^{-3\tau H^{-1/2}} \left( e^{2\tau EY\Pi^{-1} + \Omega} \right) \]
\[ + \left( e^{-3\tau H^{-1/2}Y} \right) \left( -3 - \frac{1}{2} \frac{H_\tau}{H} \right) \]
\[ = \left( e^{-3\tau H^{-1/2}Y} \right) \frac{\Pi E}{\Pi^2} + \left( e^{-3\tau H^{-1/2}Y} \right) \left( -3 - \frac{1}{2} \frac{H_\tau}{H} \right) + e^{-3\tau H^{-1/2}} \Omega \]
\[ = \left( e^{-3\tau H^{-1/2}Y} \right) \frac{\Pi E}{(e^{-\tau H^{-1/2}})^2} \]
\[ + \left( e^{-3\tau H^{-1/2}Y} \right) \left( -3 - \frac{1}{2} \frac{H_\tau}{H} \right) + e^{-3\tau H^{-1/2}} \Omega \]
\[ + \left( e^{-3\tau H^{-1/2}Y} \right) \left( -3 - \frac{1}{2} \frac{H_\tau}{H} \right) \left( \frac{\Pi E}{H} - 1 \right). \]

We insert our ansätze that \( \frac{H_\tau}{H} \to -1, e^{-3\tau H^{-1/2}} \to 0, \) and \( (\frac{\Pi E}{H} - 1) \to 0, \) to obtain the ODE

\[ \partial_\tau \bar{c} = \bar{d} - \bar{c} \left( -\frac{1}{2} \right) \]
\[ \partial_\tau \bar{d} = \frac{\bar{d}}{\bar{c}^2} + \bar{d} \left( -\frac{5}{2} \right) \]

which has a fixed point at

\[ \bar{c} = \frac{2}{\sqrt{10}}, \quad \bar{d} = \frac{1}{\sqrt{10}}. \]

So we conjecture that the quantities

\[ c := \frac{\Pi}{e^\tau \sqrt{H}} - \frac{2}{\sqrt{10}}, \quad d := \frac{Y}{e^{3\tau \sqrt{H}}} - \frac{1}{\sqrt{10}} \]

decay and compute the evolution of these quantities using (5.1) and (5.2). We find that

\[ \partial_\tau \begin{pmatrix} c \\ d \end{pmatrix} = \begin{pmatrix} -1/2 & 1 \\ -5/2 & 0 \end{pmatrix} \begin{pmatrix} c \\ d \end{pmatrix} - \frac{1}{2} \partial_\tau \log (e^\tau H) \begin{pmatrix} c \\ d \end{pmatrix} \]
\[ - \frac{1}{2} \partial_\tau \log (e^\tau H) \begin{pmatrix} \frac{2}{\sqrt{10}} \\ \frac{1}{\sqrt{10}} \end{pmatrix}. \]
\[
\left( 0 \right)^2 + \left( \frac{\Pi E}{H} - 1 \right) \frac{d + \frac{1}{\sqrt{10}}}{(c + \frac{\sqrt{10}}{2})^2} H + \frac{\Omega}{e^{3\tau} H^{1/2}}
\]

where \( f(c, d) = \frac{10c - 10d + 3\sqrt{10} c^2 - \sqrt{10} cd}{4} \) has vanishing linear part. Let

\[
\tilde{\Omega} := -\frac{1}{2} \partial_\tau \log (e^{\tau} H) \left( \frac{\sqrt{10}}{2} \right) \left( \frac{1}{\sqrt{10}} \right)
\]

\[
+ \left( \frac{f(d, c)}{(c + \frac{\sqrt{10}}{2})^2} + \left( \frac{\Pi E}{H} - 1 \right) \frac{d + \frac{1}{\sqrt{10}}}{(c + \frac{\sqrt{10}}{2})^2} H + \frac{\Omega}{e^{3\tau} H^{1/2}} \right)
\]

denote the error term of this approximation. In the end, the following estimate is obtained (cf. [13], Proposition 5.1).

**Proposition 5.1.** Consider the evolution of a \( B_0 T^2 \)-symmetric solution. Provided the corrected energy \( H \) is positive, one has for \( s \geq s_0 \)

\[
\left| \left( \frac{c}{d} \right)(s) \right| \lesssim e^{(s_0 - s)/4} \left( \frac{e^{s_0} H(s_0)}{e^s H(s)} \right)^{1/2} \left| \left( \frac{c}{d} \right)(s_0) \right|
\]

\[
+ \int_{s_0}^{s} e^{(\tau - s)/4} \left( \frac{e^{\tau} H(\tau)}{e^s H(s)} \right)^{1/2} |\omega(\tau)| d\tau,
\]

where

\[
|\omega| \lesssim \left| \tilde{\Omega} \right|
\]

Quickly note a bound on one of the terms appearing in \( \tilde{\Omega} \).

**Lemma 5.2.** Consider the evolution of a \( B_0 T^2 \)-symmetric solution. The following estimate holds.

\[
\left| e^{-3\tau} H^{-1/2} \omega \right| \lesssim e^{-2\tau} |H|^{-1/2} EY_\tau.
\]

The proof of this lemma proceeds in the same manner as the proof of inequality (4.2). The remaining three terms in \( \tilde{\Omega} \) are estimated directly. In the next section, we perform a bootstrap argument to bound these errors, provided the initial data is sufficiently close to the asymptotic behaviour.

### 6. The Bootstrap

The technique of proof follows [13]. The idea is to impose some smallness assumptions on the means of the energy, the \( S^1 \) volume, and their derivatives. We then use a bootstrap argument to show that these assumptions are improved. The reason for obtaining the estimates of Lemma 4.1 is to bound the evolution of the corrected energy \( H \). Let us discuss how that proof goes.

We have computed \( \partial_\tau (e^{\tau} H) \) in Eq. (4.1). Note that we may bound the right side of that equation by an expression of the form
\[ |\partial_\tau (e^\tau H)| \lesssim e^\tau \Pi E F + \tilde{F} = e^\tau H \frac{\Pi E}{H} F + \tilde{F} \]

where, using the results of Lemma 4.1 we can write

\[ F := \int_{S^1} e^{\rho - \tau} \rho J d\theta + e^{-\tau} \left( 1 + e^{2(\Pi E)^{1/2}} \right) (\Pi + \Pi_\tau) \]

\[ + (\Pi E)^{1/2} + e^{-\rho(s_0)/2} e^{2(\Pi E)^{1/2}} \Pi E^{1/2} \]

(6.1)

and

\[ \tilde{F} := |A| \Pi \left( e^{-\tau} \left( 1 + \frac{\Pi_\tau}{\Pi} \right) + e^{-\rho_0/2} E^{1/2} \right). \]

(6.2)

Note that \( F \) and \( \tilde{F} \) are nonnegative. We are then concerned with the quantities

\[ \int_{s_0}^{\infty} F(\tau) d\tau, \quad \text{and} \quad \int_{s_0}^{\infty} \tilde{F}(\tau) d\tau \]

which bound the evolution of \( e^\tau H \) in the bootstrap proof.

First, however, we need the following version of Grönwall’s Lemma, the proof of which is straightforward.

**Lemma 6.1** (Grönwall’s inequality). Let \( \alpha, \beta, f \) be nonnegative smooth functions on the interval \([s_0, s]\). Suppose \( f \) satisfies the differential inequality

\[ |f'| \leq \alpha + \beta f. \]

Then

\[ |f(s) - f(s_0)| \leq -f(s_0) + \left( f(s_0) + \int_{s_0}^{s} \alpha(t) dt \right) e^{\int_{s_0}^{s} \beta(t) dt}. \]

**Lemma 6.2.** There exist constants \( \epsilon, C_1 > 0 \), a constant \( M > 1 \) and a time \( s_0 > 0 \) depending on \( \epsilon \), and an open set of \( B_0 \) Einstein flows satisfying the following conditions at time \( \tau = s_0 \):

\[ |A| < 1 \quad \text{(6.3)} \]

\[ \rho_0 := \inf_{S^1} \rho > 0 \quad \text{(6.4)} \]

\[ |c| < \epsilon \quad \text{(6.5)} \]

\[ |d| < \epsilon \]

\[ \left| \frac{\Pi E}{H} - 1 \right| < 1 \]

\[ \frac{1}{2} \epsilon^{-1} < e^{s_0} < 2 \epsilon^{-1} \quad \text{(6.6)} \]

\[ e^{s_0} H(s_0) + C_1 \epsilon^{1/2} < M \epsilon e^{s_0} \]

\[ 0 < \frac{1}{M} < e^{s_0} H(s_0) - C_1 \epsilon^{1/2}. \]

(6.7)

Furthermore, for all \( \tau \in [s_0, \infty) \), the following weaker estimates hold:

\[ |c| < \epsilon^{1/4} \]

\[ |d| < \epsilon^{1/4} \]

(6.8)
\[
\left| \frac{\Pi E}{H} - 1 \right| < 3 \quad (6.9)
\]
\[
\frac{1}{2} \left( e^{s_0} H(s_0) - C_1 \epsilon^{1/2} \right) < e^{\tau} H(\tau) < 2 \left( e^{s_0} H(s_0) + C_1 \epsilon^{1/2} \right) \quad (6.10)
\]

Remark 1. Assumptions (6.3) and (6.4) are not strictly needed. One could omit these assumptions and instead gain terms involving \( A, \rho_0 \) in inequalities (6.6), (6.7), and (6.10). We have added these assumptions just to simplify the notation.

The technique of proof is a straightforward “open closed” argument:

1. Suppose estimates (6.8)–(6.10) are satisfied for \( \tau \in [s_0, s) \).
2. We improve each of the five estimates (6.8)–(6.10) at \( \tau = s \) by choosing \( \epsilon \) small.

Proof. First, let us address the existence question. Initial data for this system consists of an initial time \( s_0 \), nonzero twist constant \( K \), the number \( \int_{S^1} l \, d\theta \), and functions \( V, V_\tau, Q, Q_\tau, \rho : S^1 \to \mathbb{R} \) subject to no constraints. Given these five functions, we can then use, in turn, Eqs. (1.4), (1.5), (1.6) to determine the remaining functions \( l_\theta \) (and thus by integrating, \( l \) up to a constant), \( \rho_\tau \), and \( l_\tau \).

We have enough degrees of freedom in the initial data to find solutions such that

\[
e^{s_0} = \epsilon^{-1}, \quad A = B = c = d = \Lambda = 0, \quad \text{and} \quad e^{s_0} H(s_0) = 1.
\]

We can then choose \( M > 2 \max \left\{ 1 + C_1 \epsilon^{1/2}, \frac{1}{1 - C_1 \epsilon^{1/2}} \right\} \), depending on \( C_1 \) and \( \epsilon \) but not the initial data, to guarantee (6.6) and (6.7). Note the quantities

\[
A, \quad B, \quad c, \quad d, \quad \Lambda, \quad \text{and} \quad e^{s_0} H(s_0)
\]

are continuous in the initial data with \( C^1 \) topology. Small \( T^2 \)-symmetric perturbations of the data constructed above will not in general satisfy \( B = 0 \), but do form an open set. The intersection of this set with the set of \( B_0 \) solutions (which is closed) is an open set of solutions. Continuity guarantees that inequalities (6.3) through (6.7) are satisfied on this set.

For the estimates, we proceed in stages.

Initial Estimates From assumptions (6.8)–(6.10), we have that

\[
e^{-\tau} \lesssim H \lesssim \epsilon e^{s_0 - \tau},
\]

and

\[
\left| \frac{\Pi}{e^{\tau} \sqrt{H}} - \frac{2}{\sqrt{10}} \right| = |c| < \epsilon^{1/4}, \quad \left| \frac{Y}{e^{3\tau} \sqrt{H}} - \frac{1}{\sqrt{10}} \right| = |d| < \epsilon^{1/4}
\]

so

\[
\Pi \lesssim \left( \frac{2}{\sqrt{10}} + \epsilon^{1/4} \right) e^{\tau} H^{1/2} \lesssim \left( \frac{2}{\sqrt{10}} + \epsilon^{1/4} \right) \epsilon^{1/2} e^{(s_0 + \tau)/2}
\]

\[
\lesssim \epsilon^{1/2} e^{s_0/2} e^{\tau/2}, \quad (6.11)
\]
\[ e^{2\tau \Pi} = Y \lesssim \left( \frac{1}{\sqrt{10}} + e^{1/4} \right) e^{3\tau} H^{1/2} \]
\[ \lesssim \left( \frac{1}{\sqrt{10}} + e^{1/4} \right) e^{1/2} e^{(5\tau + s_0)/2} \lesssim e^{1/2} e^{s_0/2} e^{5\tau/2}. \quad (6.12) \]

Note that (6.9) implies that \( \Pi E \lesssim H \) on this interval, which implies that
\[ \Pi E \lesssim \epsilon e^{s_0 - \tau} < \epsilon, \quad \text{and} \quad 1 + e^{2(\Pi E)^{1/2}} \lesssim 1 + e^{\epsilon^{1/2}} \lesssim 1 \]
for sufficiently small \( \epsilon \). The bound on \( \Pi \) and the fact that \( \Pi, Y > 0 \) together imply that, for \( a < 0 \),
\[ \int_{s_0}^{s} e^{(a-1/2)\tau} \Pi \, d\tau \lesssim e^{1/2} e^{s_0/2} \int_{s_0}^{s} e^{a\tau} \, d\tau \leq C(a) e^{1/2} e^{(a+1/2)s_0} \]
and similarly
\[ \int_{s_0}^{s} e^{(a-5/2)\tau} Y \, d\tau \lesssim e^{(a-5/2)s} Y(s) - e^{(a-5/2)s_0} Y(s_0) \]
\[ - (a - 5/2) \int_{s_0}^{s} e^{(a-5/2)\tau} Y \, d\tau \]
\[ \lesssim e^{1/2} \left[ e^{as+s_0/2} - (a - 5/2)e^{s_0/2} \int_{s_0}^{s} e^{a\tau} \, d\tau \right] \]
\[ \lesssim e^{1/2} \left[ e^{as+s_0/2} - \frac{a - 5/2}{a} \left( e^{as+s_0/2} - e^{(a+1/2)s_0} \right) \right] \]
\[ \lesssim e^{1/2} \left[ e^{as+s_0/2} + C(a)e^{(a+1/2)s_0} \right] \]
\[ \lesssim C(a)e^{1/2}e^{(a+1/2)s_0}. \]

**Bound on \( \Lambda \)** To improve inequality (6.9), first note that \( \left| \frac{\Pi E}{H} - 1 \right| = \frac{\Pi}{H} |\Lambda| \). Then we may use the estimate of the correction in inequality (3.6) to obtain
\[ \frac{\Pi}{H} |\Lambda| \lesssim \frac{\Pi}{H} \left[ e^{-2\tau} |A| + e^{-\tau} \left( 1 + e^{2(\Pi E)^{1/2}} \right) \Pi E \right] \]
\[ \lesssim \frac{\Pi}{H} \left[ e^{-2\tau} + e^{-\tau} \Pi E \right] \]
\[ \lesssim e^{1/2} e^{s_0/2} e^{3\tau/2} \left[ e^{-2\tau} + e^{s_0 - 2\tau} \epsilon \right] \]
\[ \lesssim e^{1/2} e^{s_0/2} e^{-\tau/2} + e^{3/2} e^{3s_0/2} e^{-\tau/2} \]
\[ \lesssim e^{1/2} + e^{3/2} e^{s_0} \]
\[ \lesssim e^{1/2} \]

since \( H^{-1} \lesssim e^{\tau} \). Thus we may ensure
\[ \left| \frac{\Pi E}{H} - 1 \right| < 2 \]
for \( \epsilon \) small.
An Upper and Lower Bound on $H$ For the energy $H$ we have the following estimate:

$$|\partial_\tau (e^\tau H)| \lesssim e^\tau H \frac{\Pi E}{H} F + \tilde{F} \lesssim e^\tau HF + \tilde{F}$$

That is, there is a constant $C > 0$ such that

$$|\partial_\tau (e^\tau H)| \leq C \left( e^\tau HF + \tilde{F} \right).$$

The quantities $F$ and $\tilde{F}$ are the nonnegative quantities defined in equations (6.1) and (6.2). We then apply Lemma 6.1 to obtain the upper bound

$$e^s H(s) \leq \left( e^{s_0} H(s_0) + C \int_{s_0}^s \tilde{F} \, d\tau \right) \exp \left( C \int_{s_0}^s F \, d\tau \right)$$

and the lower bound

$$e^s H(s) \geq 2e^{s_0} H(s_0) - \left( e^{s_0} H(s_0) + C \int_{s_0}^s \tilde{F} \, d\tau \right) \exp \left( C \int_{s_0}^s F \, d\tau \right).$$

What we want, then, is for $\int_{s_0}^{\infty} \tilde{F} \, d\tau$ to be bounded and for $\int_{s_0}^{\infty} F \, d\tau \rightarrow 0$ as $\epsilon \rightarrow 0$.

Recall that we have assumed $e^{-\rho_0/2} < 1$ and $|A| < 1$. We compute

$$\tilde{F} = |A| \Pi \left( e^{-\tau} \left( 1 + \frac{\Pi \tau}{\Pi} \right) + e^{-\rho_0/2} E^{1/2} \right)$$

$$< e^{-\tau} (\Pi + \Pi_\tau) + \Pi^{1/2} (\Pi E)^{1/2}$$

$$\lesssim e^{1/2} e^{s_0/2} e^{-\tau/2} + e^{3/4} e^{3s_0/4} e^{-\tau/4}$$

so

$$\int_{s_0}^{\infty} \tilde{F} \, d\tau \lesssim e^{1/2} + e^{3/4} e^{s_0/2} \lesssim e^{1/4}.$$  \hspace{1cm} (6.15)

Let $C_1$ be the product of $C$ and the constant associated to the $\lesssim$ in inequality (6.15).

Inequality (6.13) becomes

$$e^s H(s) \leq \left( e^{s_0} H(s_0) + C_1 e^{1/4} \right) \exp \left( C \int_{s_0}^s F \, d\tau \right)$$

and the lower bound (6.14) becomes

$$e^s H(s) \geq 2e^{s_0} H(s_0) - \left( e^{s_0} H(s_0) + C_1 e^{1/4} \right) \exp \left( C \int_{s_0}^s F \, d\tau \right)$$

Now we turn to the bound on $F$.

$$F = \int_{S^1} e^{\rho - \tau} \rho J \, d\theta + e^{-\tau} \left( 1 + e^{2(P\Pi E)^{1/2}} \right) (\Pi + \Pi_\tau)$$

$$+ (P\Pi E)^{1/2} + e^{-\rho_0/2} e^{2(P\Pi E)^{1/2}} \Pi E^{1/2}$$

$$\lesssim e^{-3\tau} \int_{S^1} e^{\rho + l + 2\tau} J \, d\theta + e^{-\tau} (\Pi + \Pi_\tau) + (P\Pi E)^{1/2} + \Pi E^{1/2}$$
\[ \lesssim e^{-3\tau Y_\tau} + e^{1/2}e^{s_0/2}e^{-\tau/2} + e^{3/4}e^{3s_0/4}e^{-\tau/4} \]

We have previously bounded the integral of the latter terms in time by \( \epsilon^{1/4} \), so it remains to compute
\[ \int_{s_0}^{\infty} e^{-3\tau Y_\tau} d\tau \lesssim \epsilon^{1/2}. \]

So
\[ \int_{s_0}^{\infty} F d\tau \lesssim \epsilon^{1/4}. \]

Thus, in total for \( H \), we have
\[ e^s H(s) < \frac{3}{2} \left( e^{s_0} H(s_0) + C_1 \epsilon^{1/4} \right) \]
when we choose \( \epsilon \) small enough that \( \exp \left( C \int_{s_0}^{s} F d\tau \right) < \frac{3}{2} \).

Turning to the lower bound, it is useful to define \( N := e^{s_0} H(s_0) \) and \( L := C_1 \epsilon^{1/4} \). Note assumption (6.7) implies that
\[ \frac{1}{4(N + L)} (5N + 3L) > 1 + \frac{1}{4M(N + L)} > 1 + \frac{1}{4M^2} \]
so we take \( \epsilon \) small enough that
\[ 1 + \frac{1}{4M^2} > \exp \left( C \int_{s_0}^{s} F d\tau \right). \]

The lower bound from Grönwall’s inequality takes the form
\[ e^s H(s) \geq 2N - (N + L) \exp \left( C \int_{s_0}^{s} F d\tau \right) > 2N - \frac{1}{4} (5N + 3L) = \frac{3}{4} (N - L) \]
which improves the lower bound on \( e^\tau H(\tau) \).

**Bounds on** \( \Pi, Y \) Let us determine what the smallness assumptions of Lemma 6.2 imply for the error term of the ODE system of Sect. 5. Recall the conclusion of Proposition 5.1: if \( H > 0 \), then
\[ \left| \begin{pmatrix} c \\ d \end{pmatrix} \right| (s) \lesssim e^{(s_0-s)/4} \left( \frac{e^{s_0} H(s_0)}{e^s H(s)} \right)^{1/2} \left| \begin{pmatrix} c \\ d \end{pmatrix} \right| (s_0) \]
\[ + \int_{s_0}^{s} e^{(\tau-s)/4} \left( \frac{e^\tau H(\tau)}{e^s H(s)} \right)^{1/2} |\omega(\tau)| d\tau, \tag{6.16} \]

where
\[ |\omega| \lesssim |\tilde{\Omega}| = \left| -\frac{1}{2} \partial_\tau \log (e^\tau H) \left( \frac{2}{\sqrt{10}} \right) \right| \]
\[ + \left( 0 \quad \frac{\Pi E}{H} - 1 \right) \left( \frac{d}{c+\frac{1}{\sqrt{10}}}^2 + \frac{1}{e^{3\tau} H^{1/2}} \right) \]
and
\[ e^{-3\tau} H^{-1/2} \Omega \lesssim e^{-2\tau} |H|^{-1/2} E Y_\tau. \]
To begin with, note that $e^\tau H(\tau)$ has both upper and lower bounds, and so both terms of the form $\left(e^{\tau H(s)}\right)^{1/2}$ can be bounded above by a constant:

$$\left|\begin{pmatrix} c \\ d \end{pmatrix}\right|(s) \lesssim e^{(s_0-s)/4} \left|\begin{pmatrix} c \\ d \end{pmatrix}\right|(s_0) + \int_{s_0}^{s} e^{(\tau-s)/4} |\omega(\tau)| d\tau$$

$$\lesssim \epsilon + \int_{s_0}^{s} e^{(\tau-s)/4} |\omega(\tau)| d\tau. \quad (6.17)$$

To finish the bootstrap, we must bound the right side of this inequality strictly below $\epsilon^{1/4}$. We deal with each of the 4 summands in $\omega$ in the remainder of the proof.

The contribution to the right side of (6.16) from the error term $e^{-3\tau H^{-1/2}\Omega}$ is

$$\int_{s_0}^{s} e^{(\tau-s)/4} \left|e^{-3\tau H^{-1/2}\Omega}\right| d\tau \lesssim e^{-s/4} \int_{s_0}^{s} e^{-7\tau/4} \left|H^{-1/2}\Pi^{-1}\right| Y_{\tau} d\tau$$

$$= e^{-s/4} \int_{s_0}^{s} e^{-11\tau/4} \left|\frac{\Pi E}{H} \frac{1}{c + \frac{2}{\sqrt{10}}}\right| Y_{\tau} d\tau$$

$$\lesssim e^{-s/4} \int_{s_0}^{s} e^{-11\tau/4} \left|\frac{\Pi E}{H} Y_{\tau}\right| d\tau$$

$$\lesssim e^{-s/4} \int_{s_0}^{s} e^{(-1/4-5/2)\tau} Y_{\tau} d\tau$$

$$\lesssim \epsilon^{1/2} e^{(s_0-s)/4}$$

$$< \epsilon^{1/2}$$

where we have used the fact that $\frac{e^\tau H^{-1/2}}{c+\frac{2}{\sqrt{10}}} = \Pi^{-1}$ and the bootstrap assumptions.

The contribution from $\left(\frac{\Pi E}{H} - 1\right) \frac{d + \frac{1}{\sqrt{10}}}{(c + \frac{2}{\sqrt{10}})^2}$ is

$$\int_{s_0}^{s} e^{(\tau-s)/4} \left|\left(\frac{\Pi E}{H} - 1\right) \frac{d + \frac{1}{\sqrt{10}}}{(c + \frac{2}{\sqrt{10}})^2}\right| d\tau \lesssim \int_{s_0}^{s} e^{(\tau-s)/4} \epsilon^{1/2} d\tau$$

$$\lesssim \epsilon^{1/2} \left(1 - e^{(s_0-s)/4}\right)$$

$$< \epsilon^{1/2}.$$
To bound $\partial_\tau \log(e^\tau H)$, note that $e^\tau H$ has a lower bound, and use the estimates on $F$ and $\tilde{F}$ obtained above to compute

$$|\partial_\tau \log(e^\tau H)| = \frac{1}{e^\tau H} |\partial_\tau (e^\tau H)|$$

$$\lesssim \frac{1}{e^\tau H} (e^\tau HF + \tilde{F})$$

$$\lesssim F + \tilde{F}$$

$$\lesssim e^{-3\tau Y_\tau} + \epsilon^{1/2}e^{s_0/2}e^{-\tau/2} + \epsilon^{3/4}e^{3s_0/4}e^{-\tau/4}$$

So the contribution to (6.16) is

$$\int_{s_0}^{s} e^{(\tau-s)/4} \left( e^{-3\tau Y_\tau} + \epsilon^{1/2}e^{s_0/2}e^{-\tau/2} + \epsilon^{3/4}e^{3s_0/4}e^{-\tau/4} \right) d\tau$$

$$\lesssim \epsilon^{1/2} + e^{-s/4} \int_{s_0}^{s} e^{-\tau/4-\tau/2} Y_\tau d\tau$$

$$\lesssim \epsilon^{1/2} + e^{(s_0-s)/4} \epsilon^{1/2}$$

$$\lesssim \epsilon^{1/2}.$$}

Combining these estimates, we have from inequality (6.17) that

$$\left| \begin{pmatrix} c \\ d \end{pmatrix} \right|(s) \lesssim e^{(s_0-s)/4} \left| \begin{pmatrix} c \\ d \end{pmatrix} \right|(s_0) + \int_{s_0}^{s} e^{(\tau-s)/4} |\omega(\tau)| d\tau$$

$$\lesssim \epsilon + \epsilon^{1/2}$$

$$\lesssim \epsilon^{1/2}.$$}

This improves the bootstrap inequality on $c, d$.

Thus we have improved all of the bootstrap inequalities, and the proof is complete. \hfill \Box

7. Asymptotic Behaviour

We are now in a position to present the $B_0$ version of the main result of [13]. In particular, for $T^2$-symmetric vacuum spacetimes satisfying $B = 0$, we find rates of growth/decay in the expanding direction for the $\theta$-direction volume, the normalised energy, and their derivatives.

Forthcoming work will describe the qualitative behaviour of $V$ and $Q$, and the dependence of that behaviour on the conserved quantity $B$. Given our estimates above, the proof of the theorem is nearly identical to the polarised case.
**Theorem 7.1.** There exists $\epsilon_0 > 0, M > 1$ such that if $0 < \epsilon < \epsilon_0$, for any $B_0$ initial data set satisfying the smallness conditions of Lemma 6.2, the associated solution satisfies for $\tau \in [s_0, \infty)$.

\[
\begin{align*}
&\left| \begin{pmatrix} c \\ d \end{pmatrix} \right| \lesssim e^{-\tau/4} \\
&|e^\tau H - C_\infty^2| \lesssim e^{-\tau/4} \\
&|e^{-\tau/2}\Pi - \frac{2}{\sqrt{10}} C_\infty| \lesssim e^{-\tau/4} \\
&|e^{-5\tau/2}Y - \frac{1}{\sqrt{10}} C_\infty| \lesssim e^{-\tau/4} \\
&|e^{3\tau/2}E - \frac{\sqrt{10}}{2} C_\infty| \lesssim e^{-\tau/4} \\
&\langle l \rangle - l \lesssim e^{-\tau/2} \\
&\left| e^\tau - \frac{1}{2} \right| \lesssim e^{-\tau/4} \\
&\langle V \rangle - V + \left| e^{V - \tau}(\langle Q \rangle - Q) \right| \lesssim e^{-\tau/2} \\
&|V - C_V| \lesssim e^{-\tau/2} \\
&\left| \Pi^{-1}e^\rho - e^{\rho_\infty} \right| \lesssim e^{-\tau/2}
\end{align*}
\]  

(7.1) \hspace{1cm} (7.2) \hspace{1cm} (7.3) \hspace{1cm} (7.4) \hspace{1cm} (7.5) \hspace{1cm} (7.6) \hspace{1cm} (7.7) \hspace{1cm} (7.8) \hspace{1cm} (7.9) \hspace{1cm} (7.10)

for some $C_\infty > 0, C_V \in \mathbb{R}$ and $\rho_\infty : S^1 \to \mathbb{R}$.

**Remark 2.** One would also like to obtain 0-th order asymptotics for $Q$. Our technique for $V$ does not generalise to this case, and we have been unable to prove a satisfying estimate.

**Proof.** The proof proceeds as in [13]. First, observe that inequalities (6.11) and (6.12) imply that

\[ e^{-\tau} \Pi + e^{-\tau} \Pi_\tau + e^{-3\tau} Y \lesssim e^{-\tau/2}. \]

Furthermore, $\Pi E \lesssim e^{-\tau}$ and $e^\tau H$ is bounded above and below by positive constants. On the other hand

\[ |\partial_\tau (e^\tau H)| \lesssim e^\tau HF + \tilde{F} \lesssim F + \tilde{F} \lesssim e^{-\tau/4} + e^{-3\tau} Y_\tau. \]

The right side is integrable in $\tau$, so let $C_\infty := \lim_{\tau \to -\infty} \sqrt{e^\tau H}$. Note that (6.7), (6.10), (6.6), and (6.5) together imply that $4M > C_\infty^2 > \frac{1}{2M}$.

Then

\[ |C_\infty^2 - e^\tau H| \lesssim \int_\tau^\infty |\partial_\tau (e^s H)| \, ds \lesssim e^{-\tau/4} \]

giving (7.2).

Note that (6.16) now reads

\[ \left| \begin{pmatrix} c \\ d \end{pmatrix} \right| (s) \lesssim e^{-s/4} + \int_{s_0}^s e^{(\tau-s)/4} |\omega(\tau)| \, d\tau, \]
and that all of the terms of $\int_{s_0}^{s} e^{(\tau-s)/4} |\omega(\tau)| \, d\tau$ are now bounded by $e^{-s/4}$ with the exception of

$$\int_{s_0}^{s} e^{(\tau-s)/4} \left| \frac{f(d, c)}{c + \frac{2}{\sqrt{10}}} \right|^2 \, d\tau \lesssim \int_{s_0}^{s} e^{(\tau-s)/4} \left| \frac{c}{d} \right| \, d\tau$$

(7.11)

since $|(c, d)| \lesssim 1$. So

$$\left| \left( \frac{c}{d} \right) \right| (s) \lesssim e^{-s/4} + \int_{s_0}^{s} e^{-\tau/4} e^{(\tau-s)/4} \exp \left( \int_{\tau}^{s} e^{(r-s)/4} \, dr \right) \, d\tau$$

$$\lesssim e^{-s/4} + e^{-s/4} \int_{s_0}^{s} \exp \left( \int_{\tau}^{s} e^{(r-s)/4} \, dr \right) \, d\tau$$

$$\lesssim e^{-s/4} + se^{-s/4}$$

$$\lesssim e^{(\delta-\frac{1}{2})s}$$

for any $\delta > 0$. Inserting this improved estimate into (7.11) and applying Grönwall’s inequality again gives (7.1). Combining this with (7.2) yields (7.3) and (7.4).

Recall that $H = \Pi (E + \Lambda)$ and

$$|\Lambda| \lesssim e^{-2\tau} |A| + e^{-\tau} \left( 1 + e^{2(\Pi E)^{1/2}} \right) \Pi E \lesssim e^{-2\tau}.$$

Then combine (7.2) and (7.3) to obtain (7.5). The estimate (7.6) follows from (4.6) and (7.5). Estimate (7.8) follows directly from the Poincaré inequality and the bound on $E$.

To estimate $e^l$ let us note that

$$|\Pi e^l - e^{-2\tau} Y | = \left| \int_{S^1} e^{\rho(\varphi) + l(\varphi)} \left( e^{l(\varphi) - l(\theta)} - 1 \right) \, d\varphi \right| \lesssim e^{-2\tau} Y.$$  

(7.12)

One can then combine (7.12), (7.3), and (7.4) to find that $\sup_{S^1} e^l$ is bounded by a constant. Then, we estimate again

$$|\Pi e^l - e^{-2\tau} Y | = \left| \int_{S^1} e^{\rho(\varphi)} \left( e^{l(\varphi) - l(\theta)} \right) \, d\varphi \right| \lesssim \Pi \left( \sup_{S^1} e^l \right) e^\tau E \lesssim 1$$

(7.13)

and combine (7.13), (7.3), and (7.4) to obtain (7.7). The proof of (7.10) is identical to the one in [13], since we have the same bounds on $\rho_{\theta\tau}$. 
To prove (7.9), first we observe that in view of (7.8), we need only show that $|\langle V_\tau \rangle|$ is integrable. We may make the rough estimate

$$|\langle V_\tau \rangle| \lesssim e^{\tau} e^{-\rho/2} e^{\rho/4} e^{-\rho/4} \lesssim 1.$$ 

Next, observe that applying the estimates obtained so far to (3.4) and setting $B = 0$ implies that the magnitude of the right side of that equation is $\lesssim 1$. We may then make use of (7.10)

$$|\langle e^{\rho\infty} V_\tau \rangle| \lesssim e^{\rho\infty} - e^{\rho/\Pi} |\langle V_\tau \rangle| + \frac{1}{\Pi} |\langle e^{\rho} V_\tau \rangle| \lesssim e^{-\tau/2}.$$ 

The bound on $\rho_\theta$ allows us to obtain the desired estimate on $V$. $\square$

8. Numerical Evidence

The full Einstein flow is a large, quasilinear system of partial differential equations about which it is difficult even to make conjectures. This remains true even in the simplified $T^2$-symmetric case considered in this work. It has been crucial to this work to base our conjectures on evidence garnered from numerical simulations of $T^2$-symmetric Einstein flows. We summarise this numerical work in this section. A more detailed discussion of the numerical methods and results is the subject of a forthcoming paper.

Our code is a reimplementation of one previously developed by Berger to simulate $T^2$-symmetric spacetimes in the contracting direction [6], and then later in the expanding direction. We reimplemented this code in OCaml, and made a number of modifications to improve the accuracy and speed. Most importantly, we developed code to produce solutions of the $T^2$-symmetric constraint equation via a random process, which allowed us to probe the behaviour of generic $T^2$-symmetric Einstein flows.

We have developed code which samples the constraint submanifold for the $T^2$-symmetric Einstein Field Equations in a fairly generic manner. We have then evolved these initial data using a finite difference method. This generic sampling has been a crucial element allowing us to determine that the assumption $B = 0$ was necessary for our main theorem and otherwise develop our intuition about the solutions. The simulations have the expected convergence properties upon refining the spatial resolution, so we are confident that they are accurate approximations of solutions. To obtain confidence that our simulations depict behaviour which is generic for the class under consideration, we simulated on the order of 20 randomly chosen initial constraints solutions in each of the following classes: polarised, $B = 0$, and $B \neq 0$ $T^2$-symmetric. The qualitative behaviour depicted in Figs. 2, 3, and 4 is observed to be the same for all simulations in that class.

$^2$OCaml is a general purpose programming language developed primarily at INRIA. See https://ocaml.org/.
Figure 2. $S$ and $T$ flow towards a spiral sink, regardless of polarisation or the value of $B$. Although $l_{\tau}, \rho_{\tau}$ converge to the same values in all cases, the volume form $e^{\rho-\tau/2}d\theta$ causes the variables used in the plots to flow towards different values.

Figure 3. For polarised solutions, $E = E_V$ which converges to a constant. For $B = 0$ solutions, $E$ and the $V$ and $Q$ energies all converge to constants. For $B \neq 0$ solutions, however, although the total energy converges, $E_V$ and $E_Q$ do not; they oscillate with amplitude which does not decay and period matching the period of the sink in Fig. 2.

It has been useful to plot the evolution of the following quantities along each of the numerical solutions.

$$S := \partial_{\tau} \int_{S^1} l e^{\rho-\tau/2}d\theta, \quad T := \partial_{\tau} \int_{S^1} \rho e^{\rho-\tau/2}d\theta,$$

$$E_V := \int_{S^1} \left[ V_{\tau}^2 + e^{2(\tau-\rho)}V_{\theta}^2 \right] e^{\rho-\tau/2}d\theta,$$

$$E_Q := \int_{S^1} e^{2(V-\tau)} \left[ Q_{\tau}^2 + e^{2(\tau-\rho)}Q_{\theta}^2 \right] e^{\rho-\tau/2}d\theta,$$

$$W := \log \left| \int_{S^1} V_{\tau} e^{\rho-\tau/2}d\theta \right|$$

These are not the quantities that were used in the proof of our main theorem, but they capture the dynamics of the system. The volume form $e^{\rho-\tau/2}d\theta$ is used to smooth out the graphs (the integrals generally oscillate without this normalisation).

In [13], the authors are able to determine the first-order behaviour of the energy and $\Pi$, but also the first-order behaviour of $V$ and the rate of its decay to the mean value. We have generalised their results on the asymptotic values of the energy, $\Pi$ as well as the decay of $V$ and $Q$ to their means to the $B_0$ case,
but so far have been unable to derive other estimates for $V$ and $Q$. However, the numerical solutions that we have found have the property that there are constants $a, b$ such that

$$|\langle V \rangle - b\tau - a| = O(e^{-\tau/2})$$

and that

$$b = \begin{cases} 
0 & \text{if } B = 0 \\
\frac{1}{2} & \text{if } B \neq 0 
\end{cases}.$$ 

More detailed descriptions of the numerical results will be given in future work.

Appendix A. Concordance of Notations Between [5, 6, 17], and [13]

The Einstein flows under consideration in this work have been studied extensively, including many important special subsets of solutions. Unfortunately, authors have used many different coordinates for exactly the same set of spacetimes, and this document adds yet another set of coordinates. As an aid to the reader who wishes to read the cited works together, we provide in this appendix a concordance of notations used in the most frequently cited of these works.

To the best of our knowledge, all of the works in the table rely on the foliation and equations derived in [5]. This paper, [5, 6, 17] use coordinates for $T^2$-symmetric Einstein flows which are completely general. The analysis in [13] applies only to polarised $T^2$-symmetric Einstein flows and so relies on the assumption that some metric components vanish identically. In [16], future asymptotics of Gowdy solutions are derived. The notation used there is exactly the notation of [17] if one imposes the conditions $\alpha \equiv 1, K = 0$ so we omit it from the table.

In the table below, each column uses the notation internal to the document named in the first row. All of the expressions in a given row are equal. For example, the function called $P$ in [17] has the expression $2U - \log R$ in [13]. Since [13] only deals with polarised flows, the expressions in this column are only equal to those in other documents if the polarisation condition is imposed.

| Document | Notation | Expression |
|----------|----------|------------|
| [5]      | $\alpha$ | $\equiv 1$ |
| [6]      | $K$      | $= 0$      |
| [17]     | $2U$     | $- \log R$ |
| [13]     | $\alpha$ | $\equiv 1$ |
| [13]     | $K$      | $= 0$      |

Since [13] only deals with polarised flows, the expressions in this column are only equal to those in other documents if the polarisation condition is imposed.
| $\log t$          | $-\tau$                              | $\log t$          | $\log R$          | $\tau$          |
|-------------------|--------------------------------------|-------------------|-------------------|-----------------|
| $2U \alpha^{-1/2}$| $P - \tau$                           | $P + \log t$      | $2U \alpha^{-1/2}$| $V$             |
| $K^2 t^{-2} \alpha e^{2\nu}$ | $2\pi \lambda$                     | $K^2 t^{-3/2} e^{P + \frac{3}{2} \lambda}$ | $K^2 R^{-2} e^{2\eta}$ | $e^\rho$       |
| $2tU_t$           | $1 - \frac{\pi P}{2\pi \lambda}$   | $tP_t + 1$        | $2RU_R$           | $V_\tau$        |
| $t^{-1} \int_{S^1} \alpha^{-1/2} e^{4U} Q_t \, d\theta$ | $- \int_{S^1} \pi Q \, d\theta$   | $\int_{S^1} \alpha^{-1/2} e^{2P} t \, Q_t \, d\theta$ | $0$               | $\int_{S^1} e^{\rho + 2(V - \tau)} Q_\tau \, d\theta =: B$ |
