Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Intestinal host response to SARS-CoV-2 infection and COVID-19 outcomes in patients with gastrointestinal symptoms

Abstract

Background and Aims: Given gastrointestinal (GI) symptoms are a prominent extrapulmonary manifestation of COVID-19, we investigated intestinal infection with SARS-CoV-2, its effect on pathogenesis, and clinical significance.

Methods: Human intestinal biopsy tissues were obtained from COVID-19 patients (n=19) and uninfected controls (n=10) for microscopic examination, CyTOF analyses and RNA sequencing. Additionally, disease severity and mortality were examined in patients with and without GI symptoms in two large, independent cohorts of hospitalized patients in the United States (n=634) and Europe (n=287) using multivariate logistic regressions.

Results: COVID-19 cases and controls in the biopsy cohort were comparable for age, gender, rates of hospitalization and relevant comorbid conditions. SARS-CoV-2 was detected in small intestinal epithelial cells by immunofluorescence staining or electron microscopy, in 14 of 16 patients studied. High dimensional analyses of GI tissues revealed low levels of inflammation, including downregulation of key inflammatory genes including IFNG, CXCL8, CXCL2 and IL1B and reduced frequencies of proinflammatory dendritic cells compared with controls. Consistent with these findings, we found a significant reduction in disease severity and mortality in patients presenting with GI symptoms that was independent of gender, age, and comorbid illnesses and despite similar nasopharyngeal SARS-CoV-2 viral loads. Furthermore, there was reduced levels of key inflammatory proteins in circulation in patients with GI symptoms.

Conclusion: These data highlight the absence of a proinflammatory response in the GI tract despite detection of SARS-CoV-2. In parallel, reduced mortality in COVID-19 patients
presenting with GI symptoms was observed. A potential role of the GI tract in attenuating SARS-CoV-2 associated inflammation needs to be further examined.

Introduction

Gastrointestinal (GI) symptoms comprising nausea, vomiting, and/or diarrhea\(^1\) are a common extrapulmonary manifestation in Coronavirus disease 2019 (COVID-19). Additionally, the presence of GI involvement by severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) has also been suggested by clinical\(^2\), non-human primate\(^3\) and \textit{in vitro}\(^4,5\) data. However, to date, there is limited evidence of SARS-CoV-2 infection of human intestinal epithelial cells\(^6\) and there are no studies on the response of the GI immune system in COVID-19 patients.

Given the immune dysregulation seen in COVID-19\(^7,8\), we aimed to document infection of the GI tract in patients with COVID-19, to define the cellular and transcriptomic changes within the GI tract, and to determine the impact of GI symptoms on COVID-19 outcomes. Here, we present findings from well-characterized cohorts of COVID-19 patients hospitalized in tertiary care centers, from both New York City, USA and Milan, Italy, where we conducted high dimensional analyses of mucosal and systemic immune parameters and investigated disease outcomes associated with GI involvement in COVID-19 patients.

Materials and Methods

Clinical cohorts

1. Intestinal Biopsy Cohort

Endoscopic biopsies were obtained from 20 COVID-19 and 10 control patients undergoing clinically indicated endoscopic procedures after informed consent with Mount Sinai Hospital (MSH) IRB approved protocol (IRB 16-0583). The demographic characteristics of these patients
and controls are provided in Supplementary Table 1 and 2. COVID-19 severity is defined in Supplementary Table 3 and Supplementary Methods.

2. Discovery Cohort

634 subjects with COVID-19, admitted to MSH between April 1, 2020 and April 15, 2020, who met study inclusion criteria were enrolled in a Discovery Cohort under an IRB approved protocol (IRB-20-03297A) (Supplementary Methods).

3. External Validation Cohort

We analyzed a cohort of 287 patients admitted to a tertiary care center in Milan, Italy between February 22, 2020 and March 30, 2020 with COVID-19 (Supplementary Methods).

4. Internal Validation Cohort

A distinct ‘Internal Validation Cohort’ of patients who were hospitalized at MSH between April 16, 2020 and April 30, 2020 (Supplementary Methods) was analyzed using a predictive model.

Immunofluorescent (IF) microscopy

Formalin fixed, paraffin embedded tissue was analyzed (Supplementary Methods). Primary and secondary antibodies are summarized in Supplementary Table 16.

Transmission Electron Microscopy (TEM) and Electron Tomography (ET)

Biopsy specimens and infected Vero E6 cells (positive control) were examined by electron microscopy (Supplementary Methods).

Cell Culture Experiments, Virus Isolation, and Viral RNA Detection from GI biopsy tissues

Endoscopic biopsy tissue samples were homogenized, inoculated on Vero E6 monolayers under biosafety level 3 (BSL-3) conditions and monitored daily for potential cytopathic effect (CPE). Biopsy homogenate supernatants were assessed for presence of infective particles by plaque
assay (Supplementary Methods). To detect SARS-CoV-2 RNA from intestinal biopsies, a modified version of the CDC 2019-nCoV RT-qPCR was used (Supplementary Methods).

**Biopsy collection and processing for Mass cytometry (CyTOF)**

Endoscopic biopsies were processed in BSL-3 facility within 2 hours of collection to obtain suspension of the epithelial compartment (EC) and lamina propria (LP) (Supplementary Methods).

**CyTOF processing, data acquisition, and data analysis**

Cells were processed as previously described, acquired on a Helios Mass Cytometer, and de-multiplexed using the Zunder single cell debarcoder. De-barcode files were uploaded to Cytobank for analyses, followed by annotation using Astrolabe Cytometry Platform (Astrolabe Diagnostics, Inc.) and clustering using Clustergrammer2’s interactive heatmap (Supplementary Methods).

**Blood collection and processing for CyTOF**

Phlebotomy was performed on the Intestinal Biopsy Cohort patients at the time of endoscopic evaluation. Blood samples from COVID-19 patients were processed in enhanced BSL2 conditions (Supplementary Methods).

**Specimen Processing for Nucleic Acid Extraction and RNA sequencing**

Total RNA was extracted from the cells isolated from both the intestinal compartments, EC and LP cellular fractions, using Direct-zol RNA Miniprep Plus (Zymo) kit according to the manufacturer’s instructions. RNA from cases and controls was then used for qRT-PCR and RNA sequencing (Supplementary Methods).

**RNA Sequencing**

*Library preparation and sequencing*
RNA-sequencing (RNA-seq) was performed on RNA isolated from the EC and LP samples obtained from COVID-19 cases and controls (Supplementary Methods).

**Computational analyses**

*Descriptive statistics*

For univariable statistical analyses, Graph Pad Prism (version 8) was used to calculate unpaired two tailed t-test for continuous variables and either Fisher’s exact test or the Chi-square test for categorical variables.

*Multivariate model based on Discovery Cohort and External Validation cohort*

A multivariate logistic regression was utilized to model each outcome as function of GI symptoms and clinical variables including age, gender, body mass index (BMI) and comorbidities. Significant associations were determined based on 95% confidence interval (CI) based on 1000 bootstrap iterations (Supplementary Methods).

*Predictive performance based on the Internal Validation Cohort*

Only age and BMI were adjusted for, since they were the only variables significantly associated with both outcomes across different GI symptoms models in the Discovery Cohort (Supplementary Table 9). Then, the estimated model was utilized to predict the outcome of patients in the Internal Validation Cohort.

*Average treatment effect (ATE)*

ATE of GI symptoms on COVID-19 outcomes was estimated via the TMLE (Target Maximum Likelihood Estimation) package available in R Cran\(^{10}\).

*Quantification of SARS-CoV-2 nasopharyngeal (NP) viral loads*

SARS-CoV-2 viral loads were determined as previously reported\(^{11}\) (Supplementary Methods).

**ELLA Cytokine panel and defining associations with GI symptoms**
The ELLA cytokine platform measured TNF-α, IL-6, IL-8, and IL-1β. Unpaired two-tailed t-tests were used to compare individual cytokines quantified by the ELLA panel between GI symptomatic and asymptomatic groups. P-values were adjusted via Benjamini-Hochberg.

**Multiplexed proteomic assay (Olink)**

Multiplexed proteomic inflammation panel (Olink, 92 inflammation-related proteins) was used to quantify circulating cytokines using an antibody-mediated proximity extension-based assay. The Benjamini-Hochberg procedure was used to adjust P values for multiple testing.

**Consensus Clustering of Olink Data and defining associations with GI symptoms**

Consensus clustering was performed on the abundance of the 92 cytokines across all 238 samples using the R package ConsensusClusterPlus. Associations between GI symptoms and Olink proteomic data were derived using unpaired t-test comparing the symptomatic and asymptomatic groups. P-values were adjusted via Benjamini-Hochberg (10% FDR threshold of significance).

**Results**

*The gastrointestinal tract was endoscopically uninflamed in COVID-19 cases*

Twenty COVID-19 patients and 10 uninfected controls underwent esophagastroduodenoscopy, colonoscopy or both (Supplementary Table 1 and 2). Patient 10 was excluded after multiple negative SARS-CoV-2 NP PCR tests and negative COVID-19 antibody test. COVID-19 cases and controls in the biopsy cohort were comparable for age, gender, rates of hospitalization and relevant comorbidities (Supplementary Table 1). Of the COVID-19 cases, 12 were classified as asymptomatic / mild / moderate and 7 as severe (Supplementary Table 1 and 2). GI biopsies were performed after 25.9 ± 30.3 days from last
positive NP swab. Of the 19 patients, 12 (63%) had a positive SARS-COV-2 PCR swab most proximal to their biopsy while 7 (37%) had a negative swab (after previously being positive) (Figure 1A, Supplementary Table 2). COVID-19 treatment regimens and presence of GI symptoms are detailed in Supplementary Table 2. Sample allocation for different assays is detailed in Supplementary Table 2 and Supplementary Figure 1.

The GI mucosa was endoscopically uninflamed in all subjects (Figure 1B), except for one case where inflammation was attributed to transplant rejection. Histology was normal in 7 of the 17 cases examined, while the remaining (n=10) cases had a mild increase in intraepithelial lymphocytes (IEL) and / or a scant neutrophilic infiltration (Figure 1C and D, Supplementary Figure 2). CD3⁺CD8⁺ IELs and CD3⁺CD8⁻ IELs were not significantly different in patients (n=12, 10 duodenum, 2 ileum) compared to controls (n=9, 5 duodenum, 4 ileum) (Supplementary Figure 3).

Small bowel intestinal epithelial cells have robust expression of Angiotensin converting enzyme-2 (ACE2) and harbor SARS-CoV-2 antigens

Robust expression of ACE2 was noted on the small intestinal brush border in both controls and COVID-19 patients (Figure 2, A to D). Additionally, we detected SARS-CoV-2 nucleocapsid protein in small intestinal epithelial cells of 10 of 11 COVID-19 patients tested (Figure 2, E to H and J to M, Supplementary Figure 4 and Supplementary Table 4) indicative of virus infection in these cells. When present, the distribution of viral antigens was exclusively seen in the epithelium and was patchy in the upper small intestines (duodenum; Figure 2, E to H), but diffuse in the lower small intestines (ileum; Figure 2, J to M). The presence of viral antigens on IF did not correlate with the presence of histologic abnormalities. To further define viral nucleocapsid protein positive cells, co-staining with MUC2 to define goblet cells

14 was
performed. Viral nucleocapsid primarily co-localized with MUC2 representing infected goblet cells (Figure 2, O to Q). There were a few cells positive for the viral nucleocapsid protein but negative for MUC2 which tended to be located at the base of the crypts (Figure 2, P to Q). The more diffuse viral antigen staining in the ileum as compared to the duodenum is not explained by apparent differences in ACE-2 protein expression (Figure 2, A to D), however, may be explained by increased goblet cells in the ileum\(^4\) and this data appears to be consistent with organoid cultures\(^4\). As negative controls, 5 duodenal and 6 ileal biopsies from 10 patients collected prior to the pandemic (Supplementary Table 5) showed no evidence of viral antigens (Figure 2, I and N, Supplementary Figure 5).

**Ultrastructural analyses of GI tissues reveal viral particles in small intestinal epithelial cells**

Next, we performed TEM in 16 patients. Eight of these patients showed presence of 70-110 nm viral particles in the intestinal epithelial cells of the duodenum and/or ileum by TEM (Supplementary Table 4). Representative ET images (Figure 2, R to W) showed the presence of viral particles morphologically suggestive of SARS-CoV-2 in the duodenum (Figure 2, R, S, V) and the ileum (Figure 2, T, U, W), confirmed with Immuno-EM using mouse polyclonal antiserum against SARS-CoV-2 RB (Figure 2, X, Y). These particles in the exit vesicles of duodenal goblet cells (Figure 2, R, S, V) are consistent with the co-localization of MUC2 staining using IF.

**No infectious virions identified in the GI tissues of COVID-19 patients**
We inoculated Vero E6 cells with the supernatants of homogenized intestinal tissues, but did not observe any apparent cytopathic effects or plaque formation after 7-days culture. In addition, cell culture supernatants did not reveal the presence of viral RNA by RT-qPCR.

**GI lamina propria dendritic cells are depleted in COVID-19 patients**

Next, we performed mass cytometry (CyTOF) based immunophenotypic analysis on GI tissue and peripheral blood from a subset of COVID-19 cases (GI tissue, n = 13; blood, n = 10) and controls (GI tissue, n = 9; blood, n = 9) (Supplementary Table 1 and 2, Supplementary Figure 1). Lamina propria (LP) and epithelial compartment (EC) were analyzed separately. Immune populations were clustered on the basis of cell-type specific markers for both the intestinal compartments (LP and EC) and blood (Figure 3, A, C and G, Supplementary Figure 8A and 9A, Data file 1). While the overall distribution of canonical immune cell subsets in the GI LP were comparable between patients and controls (Figure 3, A and B (left panel)), few immune populations showed differences as detailed below. No clear differences in the LP could be discerned based on severity (Figure 3B (right panel), Data file 2).

In the LP, CD206^+CD1c^+ cDC2 (conventional DCs-0.4-fold decrease, p=0.01) and plasmacytoid DCs (pDCs) were reduced in COVID-19 cases (0.5 fold decrease, p=0.07) (Figure 3, D and E), analogous to changes described in the blood\textsuperscript{16}. Effector (PD-1^+CD38^+) CD4^+ and CD8^+ T cells (Figure 3F) as well as CD8^+CD103^+ T cells (tissue resident memory) (Supplementary Figure 7A) were increased in patients compared to controls (1.7-fold increase, p=0.06). In the EC, there was decrease in CD206^+cDC2 (0.4-fold decrease, p=0.05) and an increase in CD4^+CD8^- IELs (1.6-fold-increase, p=0.03) in patients compared to controls (Figure
Alterations in other immune populations in the LP and EC are shown in Supplementary Figure 7 and 8, respectively.

Among PBMCs, effector (PD-1+CD38+) CD4+ and CD8+ T cells were significantly increased in patients (Figure 3I). Alterations in monocytes, T\textsubscript{REG} and IgG\textsuperscript{+} plasma cells are shown in Supplementary Figure 9. Finally, a significant increase in activated (CD29\textsuperscript{+}CD38\textsuperscript{+}) CD4+ T cells was noted in PBMCs (Supplementary Figure 10A) and a non-significant increase of these activated T cells in the LP of patients compared to controls (Supplementary Figure 10B). Details of all immune population changes are provided in Data file S2.

Altogether, intestinal tissues of COVID-19 patients showed altered distribution of immune cell subsets, most notable for reduced frequencies of CD206\textsuperscript{+}CD1c\textsuperscript{+} cDC2 and pDCs and an increased frequency of effector T cells.

**GI lamina propria pro-inflammatory pathways are downregulated in COVID-19 patients**

Next, we performed RNA-Seq on the EC and LP in 13 COVID-19 patients and 8 controls. The EC and LP clustered separately on the basis of their top transcriptional signatures, demonstrating distinctness of the two compartments (Supplementary Figure 11, Data file 3). 1063 differentially expressed genes (DEG) were identified out of total 11419 genes detected (Figure 4A, Data file 3). The majority of DEGs were detected in the LP (1061, false discovery rate $\leq 0.05$), compared to 12 DEGs in the EC that largely overlapped with the LP (Figure 4A). Both LP and EC showed upregulation of genes involved in immunomodulation, including the anti-microbial peptide LCN2, and the metallothioneins MT1E, MT1F, MT1H, MT1M, MT1X, MT2A and TMEM107. In addition, heat shock proteins, HSPA1A and HSPA1B, were downregulated in both compartments. Pathway enrichment analysis of DEGs ranked by significance revealed
several KEGG pathways that were depleted in patients compared to controls (Figure 4B) including pathways linked to T<sub>H</sub>17 cell differentiation and inflammatory bowel diseases (IBD) which are characterized by the depletion of RORA, IL4R, IFNG, IL18R1, IL1B, STAT4 and HLA-DRA. Pathways linked to antigen processing, T<sub>H</sub>1 and T<sub>H</sub>2 cell differentiation, and MAPK signaling were significantly downregulated in the LP from patients. In contrast, genes associated with amino acid metabolism (NOS2, SMS, ALDH2, GOT2), mineral absorption (MT1G, MT2A, MT1E), and mucin biosynthesis (GALNT7, GALNT3, GALNT8) were significantly upregulated in patients compared to controls (Figure 4B).

We considered the possibility that the observed expression changes could imply alterations in relative cell type proportions (in addition to transcriptional alterations within cells). Therefore, we interrogated data derived from single-cell RNA-seq<sup>18</sup> for enrichment of cell type-specific gene expression signatures. Consistent with our CyTOF data (Figure 3 and Data files 1 and 2), genes associated with DCs and eosinophils were reduced in patients compared to controls (Figure 4C). Additionally, signatures related to the size of endothelial cell and mast cell pools were reduced, while genes linked to goblet cells, proliferating epithelial cells, enteroendocrine cells and epithelial stem cells were increased, possibly reflecting the sequelae of intestinal epithelial infection by SARS-CoV-2 and subsequent recovery (Figure 4C).

We probed myeloid gene signatures further, and found significant downregulation of genes associated with pDC (DAPK1, IRF7, ICAMI and GM2A), activated DCs (TNFAIP2, CD86, CD83), cDC1 (RELB, IRF8 and HLA-DRA) and cDC2 (CLEC7A and CLEC10A). Additionally, LP genes associated with inflammatory DCs (monocyte-derived DCs, MoDCs) (TGFB1, TGFBI, STAB1, SDCBP, RNASET2, MSR1, MRC1, MERTK, DNASE1L3, CD163L1,
C5AR1, SPI1, CSF1R, AOAH, ABCA) were significantly reduced (Figure 4D), consistent with our CyTOF results.

Next, we looked at the average EC and LP expression of recently reported gene signatures linked to the antiviral response against SARS-CoV-2 from post-mortem lung tissue\(^7\), and human intestinal organoids\(^5\). Although we did not observe a substantial acute SARS-CoV-2 response, there was significant upregulation of LCN2 in both EC and LP, and OAS and GBP3 in LP only. Notably, we observed a trend towards induction of antiviral response genes in the EC, where expression of canonical antiviral genes such as IFI44L, IFIT1, IFITM3, IFI44, IFI6 and OAS3 was increased (Figure 4E, top panel).

Finally, using gene set enrichment analysis (GSEA), we rank ordered the EC DEGs according to effect size (logFC * -logPvalue) and tested for enrichment in the reported SARS-CoV-2 infected organoid gene signatures\(^5\) (Supplementary Figure 12A). The genes upregulated in the EC of patients were significantly enriched in the SARS-COV-2 infected organoid gene datasets. Hallmark pathway enrichment analyses on this ranked EC gene list revealed that the top two processes associated with genes upregulated in EC were interferon alpha response (normalized enrichment score (NES) 1.91, FDR<0.005) and interferon gamma response (NES=1.8, FDR=0.005) (Supplementary Figure 12B), indicative of the host antiviral response against SARS-CoV-2 in the EC.

Projection of our RNA-seq dataset on SARS-CoV-2 infected human bronchial epithelial cells\(^7\) revealed that several inflammatory cytokines and chemokines such as IL-1β, IFN-γ, CCL24 and CXCL8 were downregulated in the intestines of COVID-19 patients (Figure 4E, bottom panel). The only chemokine significantly increased was CCL15 which is structurally similar to antimicrobial peptides and has a role in maintaining intestinal homeostasis\(^19\) (Figure
Key inflammatory genes including IFNG, IL1B, CXCR4, TNFSF14, CXCL2, CSF-1, CXCL8, IL18R1, NRP1 and IL18BP were downregulated in LP of patients compared to controls (Figure 4F).

Together, these data reveal a dynamic remodeling of GI tissues by SARS-CoV-2, notably with a significant downregulation of pathways associated with inflammation and antigen presentation in the LP with a concomitant activation of antiviral response signaling genes in the EC.

**Clinical impact of GI involvement during COVID-19: frequency of GI symptoms in a Discovery Cohort**

Given the observed downregulation of key inflammatory genes, we hypothesized that intestinal involvement in COVID-19 is associated with a milder disease course. We tested this hypothesis in a ‘Discovery Cohort’ consisting of 634 hospitalized COVID-19 patients at MSH meeting inclusion criteria (Supplementary Figure 13). Demographics (gender, age and race/ethnicity) and clinical variables including the presence of comorbidities and COVID-19 severity were analyzed (Supplementary Table 6). Next, we recorded the presence of GI symptoms (diarrhea, nausea, vomiting) present at the time of hospital admission, to avoid iatrogenic confounders. 299 patients (47%) reported any of the GI symptoms (nausea, vomiting and/or diarrhea) with diarrhea being the most common (245 patients, 39%), followed by nausea (157 patients, 25%), and then vomiting (82 patients, 13%) (Supplementary Table 6).

**COVID-19 severity is significantly reduced in patients with GI symptoms when compared to those without GI symptoms in multivariate analysis**
Among the Discovery Cohort, 54 (9%) patients had mild disease, 361 (57%) moderate, 158 (25%) severe and 61 (10%) had severe COVID-19 with end organ damage (EOD) (Supplementary Table 3 and 6). 110 patients were admitted to the ICU (17%) and 151 patients (24%) died by the end of data collection (Supplementary Table 6). Patients presenting with GI symptoms had less severe disease than patients without GI symptoms (p<0.001 Chi-square test, Table 1). Notably, only 54 (9%) patients in the entire cohort [31(10.3%) with and 23(6.8%) without GI symptoms respectively] had mild disease on presentation (i.e. not requiring any type of supplemental oxygen (SpO2>94% on room air) and with no evidence of pneumonia), therefore, a majority of patients with GI symptoms had concomitant respiratory symptoms. Mortality was significantly lower in COVID-19 patients with GI symptoms (15.7%) than those without GI symptoms (31.0%; p<0.0001 Fisher’s exact test) (Table 1). Furthermore, each individual GI symptom (nausea, vomiting and diarrhea) was associated with less severe disease (p<0.02 Fisher’s exact test) and lower mortality (p<0.001 Fisher’s exact test) (Supplementary Table 7). These findings were further emphasized by Kaplan-Meier estimates of survival over short-term follow-up of 25 days (p<0.001 log-rank test) (Figure 5A and Supplementary Figure 14, A and B). Consistent with prior reports older age and higher disease severity were associated with higher mortality (Supplementary Table 8).

Next, we created a multivariate model, adjusting for age, BMI, gender, race/ethnicity, diabetes, HTN, chronic lung disease and heart disease to determine the impact of GI symptoms on COVID-19 outcomes (Table 1). Consistent with published literature age and BMI were positively associated with COVID-19 severity and mortality (Supplementary Table 9). The presence of any GI symptoms, as well as diarrhea, nausea, and vomiting individually, were inversely associated with COVID-19 severity and mortality (Figure 5B, Supplementary Table 9).
Patients who presented with GI symptoms had 50% reduced odds of having severe disease (odds ratio (OR) of 0.56) and death from COVID-19 (OR of 0.54), compared to the patients who presented without GI symptoms (Figure 5B, Supplementary Table 9).

An External Validation Cohort further confirms decreased mortality in COVID-19 patients with GI symptoms on multivariate testing

Next, we confirmed our findings in an External Validation Cohort in which GI symptoms on admission were characterized as presence or absence of diarrhea (Supplementary Table 10). Consistent with the Discovery Cohort, patients with diarrhea on admission had significantly lower mortality (10.0%) compared to patients without diarrhea (23.7%, p=0.008). Additionally, patients with diarrhea had lower composite outcome of mortality or ICU admission compared to those without diarrhea (20% vs 40%, p=0.001) (Supplementary Table 10). On multivariate logistic regression analyses, adjusting for age, gender, BMI, diabetes, chronic heart and lung disease and other confounders, we observed that the presence of diarrhea on admission was significantly inversely associated with mortality with a median OR of 0.33 over 1000 bootstrap iterations (Figure 5C). In 270 patients in which treatment data was available, no specific treatment was associated with GI symptoms (p-values > 0.05) (Supplementary Table 11). In addition, diarrhea was significantly associated with mortality after adjusting for all treatments (Supplementary Table 11). Thus, our observations from this External Validation Cohort were in alignment with those from the Discovery Cohort.

Presence of GI symptoms can be used to predict reduced disease severity and mortality in COVID-19 patients
Next, we developed a predictive model based on the Discovery Cohort and applied it to a distinct Internal Validation Cohort. The inclusion of ‘any GI symptoms’ to a model consisting of age and BMI, improved the ability to predict severity and mortality with a median area under the curve (AUC) of 0.64 (age + BMI + any GI symptoms) vs 0.59 (age + BMI) for disease severity and 0.73 (age + BMI + any GI symptoms) vs 0.70 (age + BMI) for mortality (Figure 5D, Supplementary Table 12). In addition, the effect of GI symptoms, age and BMI on the AUC was evaluated by excluding each variable one at a time from the model and calculating the consequent reduction in AUC. The exclusion of GI symptoms resulted in a significant reduction in AUC with a median value of 0.054 for disease severity and 0.03 for mortality. Notably, the effect of GI symptoms on the AUC was more dramatic than that of age (AUC reduction of 0.054 versus 0.025) for disease severity (Figure 5E, Supplementary Table 12).

**Average treatment effect (ATE) of GI symptoms on COVID-19 outcomes**

Using causal inference methodology, we quantified the ATE of GI symptoms on COVID-19 outcomes while accounting for potential confounders. We performed this analysis on the MSH Cohort combining Discovery and Internal Validation Cohort and on the External Validation Cohort. The marginal effect of GI symptoms in the MSH cohort was significant for both severity and mortality after adjusting for all confounders (Data file 4). Additionally, based on the External Validation Cohort, the ATE for diarrhea was significant for mortality and combined outcome of ICU admission or death, but not for ICU admission alone (Data file 4). The OR for the marginal treatment effect of diarrhea was 0.9 for mortality in both the MSH and External Validation Cohort.
Nasopharyngeal SARS-CoV-2 viral loads are similar in patients with and without GI symptoms.

Given recent reports suggesting that NP SARS-CoV-2 viral loads are correlated with disease outcomes, we compared NP viral loads in a subset of Discovery and Internal Validation Cohort (n=329, where data available). Patients with and without GI symptoms had comparable SARS-CoV-2 NP viral loads (mean log_{10} copies/mL 5.1 (SD 2.3) and 5.6 (SD 2.4), respectively) (p=0.07); furthermore, no significant differences were observed for each individual GI symptom (Figure 5F).

COVID-19 patients with GI symptoms have reduced levels of circulating cytokines associated with inflammation and tissue damage.

To correlate the observed mortality difference with GI symptoms with known biomarkers for severe COVID-19, we examined IL-6, IL-8, TNF-α, and IL-1β levels measured on admission. IL-6 and IL-8, which are known to be directly associated with poor survival, were found to be significantly reduced in circulation of patients with GI symptoms (FDR 10%) (Supplementary Figure 15, Supplementary Table 13).

Next, we performed a validated, multiplexed proteomic assay (Olink), in 238 patients (from among the Discovery and Internal Validation Cohorts; GI symptoms (n=104), no GI symptoms (n=134)) where serum samples were available for analyses. Unsupervised consensus clustering of 92 analytes revealed six groups of analytes with similar expression patterns across all patients (Figure 6A, Supplementary Table 14). Analytes in clusters 5 and 6 displayed less correlation in patients with GI symptoms compared to those without GI symptoms (Figure 6A, Supplementary Figure 16). “KEGG Jak/Stat Signaling Pathway” was significantly enriched in Cluster 5; while the "Hallmark Inflammatory Response" pathway was significantly enriched in
Cluster 4 (Fisher’s exact test 10% FDR). These pathways were downregulated in patients with diarrhea (p<0.05 from t-test) (Figure 6B), suggesting a reduced inflammatory response in patients with GI symptoms. Additionally, Clusters 1, 2, 3, 5 and 6 were significantly downregulated in patients with GI symptoms compared to those without (FDR 15%) (Figure 6C). This seemed to be driven mostly by diarrhea since the same clusters were significantly downregulated in patients with diarrhea (FDR 10%). We observed a similar, albeit a reduced signal for nausea and vomiting likely due to the smaller sample size (n=29 for vomiting, n=54 for nausea).

Key inflammatory cytokines and chemokines were significantly downregulated (IL-8, TGF-α, IL-17C, IL-15RA, IL-10RB, MMP10, TNFRSF9, OPG, IL-6, LIF, GDNF, IL-17A, ARTN and CCL28) while TNF-Related Apoptosis Inducing Ligand (TRAIL), a cytokine with immune regulatory properties and IL-7, a cytokine associated with T cell development were significantly upregulated in patients with GI symptoms (t-test FDR 10%) (Figure 6, D and E, Supplementary Table 15).

Overall, GI symptoms are associated with significantly reduced levels of key inflammatory cytokines including IL-6, IL-8, IL-17 and CCL28 that are known to be associated with poor COVID-19 outcomes.

Discussion

Given the robust expression of ACE2 on the small intestinal epithelium, we hypothesized that the intestines would be susceptible to SARS-CoV-2 infection. Here, we detailed for the first time SARS-CoV-2 infection of human intestinal epithelial cells in vivo using IF and EM. Specifically, infected intestinal cells were primarily goblet cells. We also observed a mild
inflammatory response in the intestinal tissues despite the presence of SARS-CoV-2 antigens. Finally, we found reduced systemic inflammation as well as mortality in hospitalized COVID-19 patients presenting with GI symptoms.

Using multiple approaches, we observed evidence of reduced inflammatory response within the GI tract. This includes a lack of inflammatory monocytes and macrophages and a depletion of DC subsets in the GI tract which is in contrast to the significant inflammatory response observed in the blood and lungs of severe COVID-19 patients. Additionally, a downregulation of several proinflammatory genes that were found to be elevated in the lungs during SARS-CoV-2 infection was observed in GI tissues. Lastly, systemic levels of IL-6 and IL-8 as well as IL-17 and CCL28 were lower in hospitalized patients presenting with GI symptoms, despite comparable NP SARS-CoV-2 viral loads. Notably, the reduced circulating IL-17 and CCL28 (by Olink) is consistent with our RNAseq data. The observed attenuation of GI inflammation is in alignment with data from the 2003 SARS epidemic, autopsy studies from COVID-19 patients and from animal models.

In two distinct and large cohorts of COVID-19 patients, we observed a significant reduction in mortality in patients presenting with GI symptoms compared to those without GI symptoms, even after adjusting for multiple confounders including age and comorbidities, which is consistent with findings in two smaller cohorts. Notably this finding is different from early reports suggesting increased severity with GI symptoms, likely attributable to the inclusion of abnormal liver function tests which are associated with poor outcomes.

We duly acknowledge some limitations of our study. GI biopsies were performed on a distinct set of patients undergoing clinically indicated procedures and therefore, they were not all in the acute phase of illness. Furthermore, given only 3 patients in the biopsy cohort had GI
symptoms, we were unable to perform comparisons between those with and without GI symptoms. Although we could not isolate infectious virus from intestinal biopsies (possibly due to culture methods, low multiplicity of infection or inactivation of virus following contact with enteric secretions) we demonstrate presence of virus in intestinal tissue using two parallel methods, IF and EM/ET. One of the possible reasons why SARS-CoV-2 induced less severe inflammation in the gut could be through the induction of potent neutralizing IgA antibodies which are predominantly produced in the intestines and do not fix complement unlike IgG antibodies mainly induced in the lungs\textsuperscript{33, 34}. Furthermore, dimeric IgA (as would be induced in the gut) is more potent in viral neutralization than IgG\textsuperscript{35}. Finally, we acknowledge that reporting of GI symptoms can be subject to individual variation and has the potential for being under reported.

In summary, our data detail the previously unappreciated GI tissue response to SARS-CoV-2 and provide the rationale for future mechanistic studies to understand a possible attenuation of SARS-CoV-2 pathogenicity by the intestinal environment.

Figures and Table Legends

Figure 1 Clinical timing, endoscopic findings and histologic features in the small intestines of COVID-19 patients. (A) Timing of GI evaluation with respect to COVID-19 disease course. (B) Representative endoscopic images of the duodenum in COVID-19 (left) and control (right) patients. (C) Histologically normal duodenal tissue in a COVID-19 patient. (D) Histologic signs of inflammation detected in duodenal biopsies of COVID-19 patients including neutrophils (arrow) and increased intraepithelial lymphocytes (*). Scale bar; 100 µm.
Figure 2 SARS-CoV-2 viral particles and protein are detectable in intestinal tissues of COVID-19 patients. (A-H) Immunofluorescence (IF) staining of duodenal (A, B) and ileal (C, D) biopsies of COVID-19 patients (B, D) and controls (A, C) with ACE2 (green), EPCAM (red) and DAPI (blue). (E-N) IF staining of duodenal (E-I) and ileal (J-N) biopsies from patients (E-H, J-M) and controls (I, N) with SARS-CoV-2 nucleocapsid (green), EPCAM (red) and DAPI (blue) including isotype (G, L) and no primary (H, M) controls. (O-Q) IF staining of duodenal (O, P) and ileal (Q) biopsies of patients with SARS-CoV-2 nucleocapsid (green), MUC2 (red) and DAPI (blue) showing SARS-CoV-2 nucleocapsid in goblet cells (*, MUC2+) and non-goblet epithelial cells (arrows, MUC2-). (R-W) Electron tomography (ET) of a duodenal biopsy (R, montaged projection overview; S, Tomographic reconstruction of the region indicated by the rectangle in R showing the goblet cell Golgi region; V, Detail of the presumptive virion indicated by the red arrow in S. Note dark nucleocapsid puncta and surface spikes (arrows). ET of an ileal biopsy from a COVID-19 patient (T), montaged tomographic reconstruction of a goblet cell Golgi region; U, Detail of the region indicated by the rectangle in T, showing a presumptive exit compartment containing 5 presumptive SARS-CoV-2 virions; W, Detail of a presumptive virion from U, membrane bilayer and surface spikes are evident. The virion structures in R-W are comparable with those from a SARS-CoV-2–infected cultured cell (Supplementary Figure 6 and Supplementary Movies 1-2). Projection image (X) of a presumptive SARS-CoV-2 virion within an intestinal epithelial cell of CGI-115, labeled with a mouse polyclonal antiserum against SARS-CoV-2 RBD36 and 10 nm gold conjugated anti-mouse secondary antibodies. Detail of the presumptive virion itself is not apparent in the projection image. A single slice (Y) (~10 nm) from a tomographic reconstruction of the same area shown in X. The spherical shape and membrane bilayer of the presumptive CoV-2 virion (indicated by *)
are discernible, with gold particles connoting anti-S labeling localized to the presumptive virion’s outer periphery. Scale bars; 100 µm (A-N), 10 µm (O-Q), 5 µm (R), 0.2 µm (S, U), 1 µm (T), 0.05 µm (V, W), 0.025 µm (X,Y).

Figure 3 CyTOF-based analysis identified immune cell signatures in intestinal biopsies and blood from COVID-19 patients and controls. Uniform Manifold Approximation and Projection (UMAP) presentation of the eight clusters of LP immune populations based on 38 markers (A), by infection status (B, left panel) with COVID-19 patients (red) and controls (blue), and by disease severity (B, right panel) with controls (blue), severe (red) and asymptomatic/mild/moderate (green) COVID-19 patients. (C) The heatmap depicting immune populations in the LP based on specific cell type markers. (D) Representative histograms comparing CD206^+ and CD123^+ in DC subsets in patients (red) and controls (blue). (E) Relative frequencies of CD206^+ cDC2 and plasmacytoid DCs in LP of patients and controls (unsupervised analysis). (F) Relative frequencies of PD-1^+ CD38^+ (effector) CD4^+ and CD8^+ T cells in LP of control and patients (supervised analysis). (G) UMAP presentation of the eight clusters of immune populations based on 38 markers in the EC of intestinal biopsies. (H) Relative frequencies of CD206^+ cDC2 and CD4^-CD8^- T cells in the EC of controls and patients (unsupervised analysis). (I) Relative frequencies of PD-1^+ CD38^+ (effector) CD4^+ and CD8^+ T cells in blood of controls and patients (supervised analysis). Open red circles denote patients with asymptomatic/mild/moderate disease while filled red circles denote patients with severe COVID-19. Bar plots represent median values.
Figure 4 Transcriptional changes in intestinal biopsies from COVID-19 patients compared with controls. (A) Hierarchical clustering of average expression changes for 1,063 genes (rows) with induced (red) or depleted (blue) expression (FDR ≤ 0.05) in the EC and LP of intestinal biopsies from COVID-19 patients. The panel on the left indicates significant genes for each tissue fraction in yellow. The color bar indicates the average log2 fold-change (FC). (B) Top enriched pathways (KEGG) that are induced (red) or depleted (blue) in LP of COVID-19 patients are displayed. The dash line indicates the $P \leq .05$ cutoff. Gene names are indicated for main pathways. (C) Deconvolution of main gastrointestinal cell types enriched or depleted in the LP of COVID-19 patients compared with controls. Reference scRNA-seq cell type signatures were taken from Smillie et al. 2019. (D) Average expression changes for dendritic cell markers in the EC and LP. Reference scRNA-seq cell type signatures were taken from Martin et al. 2019. The color bar indicates the average log2 FC. (E) Hierarchical clustering of average expression changes (columns) in the EC and LP for genes related to antiviral response to SARS-CoV-2 in post-mortem lung tissue of COVID-19 patients as described by Blanco-Mello et al. 2020 (top panel) and for cytokines and chemokines (bottom panel). The color bar indicates the average log2 FC. (F) The gene expression levels for the top 10 significant chemokines and cytokines in the LP of COVID-19 patients and controls. * $P < .05$, ** $P < .01$.

Figure 5 COVID-19 patients with GI symptoms had reduced severity and mortality despite similar nasopharyngeal viral loads compared to those without GI symptoms. (A) Kaplan-Meier (KM) curves for survival stratified by any GI Symptoms (left panel) and diarrhea (right panel) for patients in the Discovery Cohort. P-values from log-rank test and 95% confidence intervals of KM curves are shown. The number of patients at risk are reported for the respective
timepoints. (B) Confidence intervals (CI) of odds ratio (95%) of GI symptoms based on 1000 bootstrap iterations in a multivariate logistic regression for severity (blue) and mortality (red). (C) Validation based on the External Cohort. CI of odds ratio (95%) of diarrhea covariate based on 1000 bootstrap iterations to capture mortality, ICU admission and composite outcome of ICU admission or death. Results are based on multivariate models after accounting for confounders including BMI, age, gender, lung disease, heart disease and hypertension. (D) Validation based on the Internal Cohort. Boxplot of AUC over 1000 bootstrap iterations to predict mortality and disease severity in the Internal Validation Cohort. (E) CI of the reduction in AUC (95%) based on 1000 bootstrap iterations for the model “Age + BMI + Any GI Symptoms” after removing age (blue), GI symptoms (red) and BMI (green). (F) SARS-CoV-2 viral load copies per mL (log$_{10}$ transformed based on N2 primer with the addition of a constant) stratified by GI symptoms. The square corresponds to the average viral load and the error bars show one standard deviation of uncertainty from the mean. P-values from two-tailed unpaired t-tests are reported.

**Figure 6** COVID-19 patients with GI symptoms have reduced levels of circulating inflammatory cytokines. (A) Correlation matrix (Pearson’s) for 92 markers in the Olink panel across patients with any GI symptoms (top left panel) compared with no GI symptoms (top right panel) and patients with diarrhea (bottom left panel) compared with patients without diarrhea (bottom right panel). Cluster assignment is reported on the top of the heatmap. (B) Boxplot of “Hallmark Inflammatory Response” and “KEGG JAK/STAT Signaling pathway” z-scores stratified by GI symptoms which were significantly enriched at 10% FDR in Cluster 4 and Cluster 5, respectively. (C) Significant associations between proteomic clusters and GI symptoms at 10% (dark blue) and 15% (light blue) FDR based on unpaired two-tailed t-test. (D)
Analytes associated with GI symptoms at 10% FDR based on unpaired t-test. The intensity of the color is proportional to the -log10 p-value. Negative associations are in blue, while positive associations in red. On the right side of the heatmap, the cluster assignment for each marker is reported. (E) Boxplots represent median and interquartile range of select differentially expressed markers stratified by GI symptoms. P-values from unpaired t-test are reported.

Table 1 Basic demographics, clinical characteristics and outcomes in patients with and without GI symptoms. For age, the mean ± standard deviation is listed and an unpaired two-tailed t-test was performed. For categorical variables, the number of patients followed by the percent of patients in parentheses is listed and the Fisher’s exact test or the Chi-square test was used as appropriate.

**Data and materials availability:** Will be made available upon acceptance.
Table 1 Basic demographics, clinical characteristics and outcomes in patients with and without GI symptoms. For age, the mean ± standard deviation is listed and an unpaired two-tailed t-test was performed. For categorical variables, the number of patients followed by the percent of patients in parentheses is listed and the Fisher’s exact test or the Chi-square test was used as appropriate.

| GI symptoms (n=299) | No GI symptoms (n=335) | P-value |
|---------------------|------------------------|---------|
| Age (years)         | 60.5 ± 15.0            | 67.2 ± 15.7 | <.0001 |
| Male                | 168 (56.2)             | 201 (60.0) | .33    |

| Race/ethnicities     |
|----------------------|
| Hispanic             | 85 (28.4)             | 92 (27.5) | .13 |
| African-American     | 66 (22.1)             | 95 (28.4) |
| White                | 70 (23.4)             | 67 (20.0) |
| Asian                | 22 (7.4)              | 13 (3.9)  |
| Other                | 56 (18.7)             | 68 (20.3) | .13 |

| Comorbidities        |
|----------------------|
| HTN                  | 112 (37.5)            | 117 (34.9) | .51 |
| Diabetes             | 58 (19.4)             | 83 (24.8)  | .13 |
| Obesity (BMI>30)*    | 108 (40.6)            | 103 (34.1) | .12 |
| Chronic lung disease | 34 (11.4)             | 25 (7.5)   | .10 |
| Heart disease        | 48 (16.1)             | 63 (18.8)  | .40 |
| Chronic kidney disease | 41 (13.7)             | 54 (16.1)  | .44 |
| Cancer               | 27 (9.0)              | 39 (11.6)  | .30 |
| HIV                  | 5 (1.7)               | 6 (1.8)    | .99 |
| IBD                  | 4 (1.3)               | 3 (0.9)    | .71 |

| Disease severity     |
|----------------------|
| Mild                 | 31 (10.4)             | 23 (6.9)   |
| Moderate             | 188 (62.9)            | 173 (51.6) |
| Severe               | 63 (21.1)             | 95 (28.4)  |
| Severe with EOD      | 17 (5.7)              | 44 (13.1)  | .0004 |

| Outcomes             |
|----------------------|
| ICU admission        | 45 (15.1)             | 65 (19.4)  | .17 |
| Mortality            | 47 (15.7)             | 104 (31.0) | <.0001 |
Short summary: Intestinal infection with SARS-CoV-2 is associated with a mild inflammatory response and improved clinical outcomes.

What you need to know

BACKGROUND AND CONTEXT

Gastrointestinal manifestations are common in COVID-19, however to date, there is limited evidence of SARS-CoV-2 infection of human enterocytes, tissue immune responses and relationship to clinical outcomes.

NEW FINDINGS

Immunofluorescence and electron microscopic detection of SARS-CoV-2 in small intestinal biopsies obtained from patients with COVID-19.

Downregulation of key inflammatory pathways and reduced myeloid cells in intestinal biopsies.

Lower severity and mortality in COVID-19 patients with GI symptoms in a multivariable model in 2 large independent cohorts from the United States and Europe.

LIMITATIONS

Clinical documentation of GI symptoms might vary depending on providers and on the acuity of the patients’ presentation.

IMPACT

These data demonstrate in vivo GI tract infection by SARS-CoV-2 and the clinical impact of GI symptoms on COVID-19 outcomes in two large patient cohorts.
Intestinal host response to SARS-CoV-2 infection and COVID-19 outcomes in patients with gastrointestinal symptoms

Supplementary materials and methods

Clinical cohorts

1. Intestinal Biopsy Cohort

Subjects included hospitalized patients at Mount Sinai Hospital (MSH) as well as those seen in the outpatient GI practices that underwent endoscopy between April 17, 2020 and June 2, 2020. COVID-19 cases and controls were defined on the basis of nasopharyngeal SARS-CoV-2 swab PCR tests. Inclusion criteria included: (1) A positive nasopharyngeal (NP) SARS-CoV-2 PCR test, relevant clinical symptoms and serological evidence of anti-SARS-CoV-2 antibodies (for cases), and a negative NP SARS-CoV-2 test AND absence of fever, cough, shortness of breath and relevant contact history (for controls); (2) Clinical indication for endoscopic procedure; and (3) The patient and/or his/her health care proxy’s ability to provide informed consent. Exclusion criteria included: (1) Comorbid conditions including severe coagulopathy; (2) concomitant anticoagulation use; (3) critical illness and any other clinical parameter which could potentially increase the risk of additional research biopsies; and (4) Failure to obtain consent. COVID-19 severity was defined based on internal scoring system developed by the Department of Infectious Diseases at MSH. This scoring system was developed according to the WHO Ordinal Clinical Progression/Improvement Scale (https://www.who.int/publications/i/item/covid-19-therapeutic-trial-synopsis) and based on oxygenation status and organ damage, with the following definitions: Mild - SpO2>94% on room air AND no pneumonia on imaging, Moderate - SpO2<94% on room air OR pneumonia on imaging, Severe - high flow nasal cannula (HFNC), non-rebreather mask (NRBM), Bilevel Positive Airway Pressure (non-invasive positive airway
ventilation), or Mechanical ventilation AND no pressor medications AND creatinine clearance > 30 AND ALT < 5x upper limit of normal, Severe with evidence of end organ damage (EOD) - high flow nasal canula (HFNC), non-rebreather mask (NRBM), Bilevel Positive Airway Pressure (non-invasive positive airway ventilation), or Mechanical ventilation AND pressor medications OR creatinine clearance <30 OR new renal replacement therapy OR ALT > 5x upper limit of normal (Supplementary Table 3).

2. Discovery Cohort

Patients admitted to MSH between April 1, 2020 and April 15, 2020 were recruited into the Discovery Cohort if they were SARS-CoV-2 PCR positive, more than 18 years of age and if the “ELLA panel of cytokines” (IL-6, IL-8, IL-1β and TNF-α) was performed as part of clinical care. Clinical details from eligible patients were extracted from Mount Sinai Data Warehouse (MSDW) under an IRB approved protocol (IRB-20-03297A North American registry of the digestive manifestations of COVID-19). Inclusion criteria included (1) A positive NP SARS-CoV-2 PCR test within the Mount Sinai Health System between April 1-15, 2020 and admission to the Mount Sinai Hospital; (2) Age >18 years of age; and (3) Patients who had an ELLA cytokine panel performed during hospitalization. Exclusion criteria included (1) Testing at a site outside of Mount Sinai Hospital in an ambulatory setting or those who were tested in the emergency room but not admitted; (2) Patients <18 years of age; and (3) Patient’s without an ELLA cytokine panel.

A total of 634 subjects were included in the Discovery Cohort (Supplementary Figure 11). In addition to demographic information (including race and ethnicity, age and gender), clinical characteristics, laboratory data and outcomes data was extracted from the medical charts. Co-
variates that were studied included: BMI (obesity defined as BMI >30) and comorbid conditions including, hypertension, diabetes, chronic lung disease (including asthma and COPD), heart disease (including coronary artery disease, atrial fibrillation and heart failure), chronic kidney disease, cancer, HIV, and inflammatory bowel disease (IBD).

GI symptoms were defined as more than one episode of either diarrhea, nausea, and/or vomiting at the time of admission. If only one episode of either diarrhea, nausea, and/or vomiting was specifically documented, patients were not considered to have GI symptoms. Additionally, we did not consider GI symptoms that developed during the course of hospitalization, as they could reflect nosocomial or treatment-related effects and only considered the GI symptoms that were present at the time of hospital admission so as to avoid including iatrogenic confounders (treatments or hospital acquired illnesses that can result in diarrhea, nausea and vomiting).

Disease severity (as described above) and mortality were considered as outcomes variables. Mortality was calculated as patient status (dead or alive) at 25 days post admission. If no information was available after discharge, patients were censored at the time of hospital discharge.

3. External Validation Cohort

This cohort consisted of 287 patients admitted to a tertiary care center in Milan, Italy between February 22, 2020 and March 30, 2020, with a confirmed positive SARS-CoV-2 PCR and who did not die or were not transferred to the ICU within 24 hours from admission were studied as detailed in Aghemo et al. Presence of vomiting and diarrhea (defined as at least three loose bowel movement per day) on or prior to admission was recorded. Outcomes were analyzed using ICU admission, death or the composite study end-point of ICU admission or death within 20 days of hospitalization.
4. Internal Validation Cohort

The Internal Validation Cohort is a distinct cohort of patients admitted to MSH between April 16, 2020 and April 30, 2020 used to test a predictive model for COVID-19 severity and mortality. The same inclusion and exclusion criteria as in the Discovery Cohort were used with the following differences: (1) A positive SARS-CoV-2 PCR test between April 16, 2020 and April 30, 2020; (2) An additional exclusion of patients that were already included in the Discovery Cohort. From a total of 408 patients, 242 met inclusion criteria and were thus included in the Internal Validation Cohort. Demographic, clinical and outcomes related data was extracted from patients’ medical records as described for the Discovery Cohort.

SARS-CoV-2 testing

The SARS-CoV-2 PCR was run in the Clinical Microbiology laboratory as part of routine care on the Roche cobas platform which performs selective amplification of 2 targets ORF-1 gene (Target 1) and the E-gene for pan-Sarbecovirus (Target 2) (detects SARS-CoV-2 as well as SARS or MERS viruses, but not routine seasonal Coronavirus). A positive result indicated that either both Target 1 and Target 2 were detected (majority of cases) or Target 1 alone was detected. A presumptive positive result indicates a negative Target 1 result and a positive Target 2 result which according to the manufacture can be a result of the following: “1) a sample at concentrations near or below the limit of detection of the test, 2) a mutation in the Target 1 target region in the oligo binding sites, or 3) infection with some other Sarbecovirus (e.g., SARS-CoV or some other Sarbecovirus previously unknown to infect humans), or 4) other factors.” Patients with a presumptive positive SARS-CoV-2 PCR were included in the analysis if they were treated clinically as having COVID-19.
**Immunofluorescent (IF) microscopy**

Sections (5µm) of formalin fixed, paraffin embedded tissue were dewaxed in xylene and rehydrated in graded alcohol and then washed in phosphate-buffered saline (PBS). Heat-induced epitope retrieval was performed by incubating slides in a pressure cooker for 15 minutes on high in target retrieval solution (Dako, S1699). Once slides cooled to room temperature, they were washed twice in PBS and then permeabilized for 30 minutes in 0.1% tritonX-100 in PBS. Non-specific binding was blocked with 10% goat serum for 1 hour at room temperature. Sections were then incubated in primary antibodies diluted in blocking solution overnight at 4°C. Primary and secondary antibodies are summarized in Supplementary Table 16. Slides were washed in PBST (0.1% tween 20, PBS) thrice and then incubated in secondary antibody and 4′,6-diamidino-2-phenylindole (1µg/mL) for 1 hour at room temperature. Sections were washed twice in PBST and once in PBS then mounted with Fluoromount-G (Electron microscopy sciences, 1798425). Controls included, omitting primary antibody (no primary control), or substituting primary antibodies with non-reactive antibodies of the same isotype (isotype control). Tissue was visualized and imaged using a Nikon Eclipse Ni microscope and digital SLR camera (Nikon, DS-Qi2).

**IEL quantification**

Three-10x non-overlapping IF images were taken for each biopsy. Twelve biopsies (10 duodenum, 2 ileum) from 11 COVID-19 patients in the biopsy cohort were analyzed along with 9 uninfected controls (5 duodenum, 4 ileum). CD3+ intraepithelial lymphocytes (IELs) and CD3+ CD8+ (IELs) were quantified for each image. The length of epithelium in each image was measured in ImageJ². Biopsies from COVID-19 patients and controls were compared via unpaired t test.
**Routine Clinical Electron Microscopy (EM)**

Following post-fixation in 1% osmium tetroxide, tissues were serially dehydrated and embedded in epoxy resin in standard fashion. One-micron toluidine-stained scout sections were prepared for light microscopic orientation; 80 nm ultrathin sections for EM were stained with uranyl acetate and lead citrate and examined in a Hitachi 7650 transmission electron microscope at 80kV.

**Infection of cultured cells for EM and Electron Tomography (ET) analyses**

Viral infections of cultured cells were conducted at the UVM BSL-3 facility under an approved Institutional Biosafety protocol. SARS-CoV-2 strain 2019-nCoV/USA_USA-WA1/2020 (WA1) was generously provided by Kenneth Plante and the World Reference Center for Emerging Viruses and Arboviruses at the University of Texas Medical Branch and propagated in African green monkey kidney cells (Vero E6) that were kindly provided by J.L Whitton. Vero E6 cells were maintained in complete Dulbecco's Modified Eagle Medium (cDMEM; Thermo Fisher, Cat. #11965–092) containing 10% fetal bovine serum (Gibco, Thermo-Fisher, Cat. #16140–071), 1% HEPES Buffer Solution (15630–130), and 1% penicillin–streptomycin (Thermo Fisher, Cat. #15140–122). Cells were grown in a humidified incubator at 37°C with 5% CO₂. Vero E6 cells seeded in six well dishes and infected with SARS-CoV-2 at a multiplicity of infection of 0.01 for 48 hours before fixing and preparing for electron microscopy. Cells were pre-fixed with 3% glutaraldehyde, 1% paraformaldehyde, 5% sucrose in 0.1M sodium cacodylate trihydrate,
removed from the plates and further prepared by high-pressure freezing and freeze-substitution as described below.

**Electron Microscopy and Dual-Axis Tomography of Intestinal Biopsy Tissue**

Tissue samples were fixed with 3% glutaraldehyde to meet biosafety requirements. Tissues were rinsed with cold 0.1M sodium cacodylate trihydrate + 5% sucrose and further dissected to block sizes sufficient for high-pressure freezing. Tissues or cultured cells were rinsed with 0.1M cacodylate buffer containing 10% Ficoll (external cryoprotectant), placed into brass planchettes (Ted Pella, Inc.) and ultra-rapidly frozen with a HPM-010 High Pressure Freezing Machine (Bal-Tec/ABRA, Switzerland). Vitreously frozen samples were transferred under liquid nitrogen to Nalgene cryogenic vials (Thermo-Fisher Scientific) containing a frozen mixture of 2% OsO₄, 0.05% uranyl acetate in acetone. Vials were placed in a AFS-2 Freeze-substitution machine (Leica Microsystems, Vienna) and the samples freeze-substituted for 72 h at -90°C. Samples were then warmed to -20°C over 24 h and held at that temperature for a further 12 h before being warmed to room temperature, rinsed 3x with acetone, then infiltrated into Epon-Araldite resin (Electron Microscopy Sciences). Samples were flat-embedded between two Teflon-coated glass microscope slides and the resin polymerized at 60 °C for 24 h. Embedded tissue blocks were observed by light microscopy to ascertain preservation quality and select regions of interest (i.e., apical epithelium). Blocks were extracted with a scalpel and glued to plastic sectioning stubs prior to sectioning. Semi-thin (150 nm) serial sections were cut with a UC6 ultramicrotome (Leica Microsystems) using a diamond knife (Diatome, Ltd. Switzerland). Sections were placed on formvar-coated copper-rhodium slot grids (Electron Microscopy Sciences) and stained with 3% uranyl acetate and lead citrate. Colloidal gold particles (10 nm) were placed on both surfaces
of the grids to serve as fiducial markers for tomographic image alignment. Grids were placed in a
dual-axis tomography holder (Model 2010, E.A. Fischione Instruments, Export PA) and imaged
with a Tecnai G2 T12 transmission electron microscope (120 KeV; ThermoFisher Scientific).
Images were recorded with a 2k x 2k CCD camera (XP1000; Gatan, Pleasanton, CA).
Tomographic tilt series and large-area montages were acquired automatically using the SerialEM
software package. For dual-axis tomography, images were collected at 1° intervals as samples
were tilted +/- 62°. The grid was then rotated 90° and a second tilt-series was acquired about the
orthogonal axis. Tomograms were calculated, analyzed and modeled using the IMOD software
package on MacPro and iMac Pro computers (Apple, Inc).

Presumptive SARS-CoV-2 virions were identified from tomographic reconstructions of
tissue samples by observing structures resembling virions described in cryo-electron tomography
studies of purified SARS-CoV-2 and SARS-CoV-2 in infected cells and comparing to
identified virions within SARS-CoV-2–infected cultured cells (Supplementary Figure 6). We
used the following criteria for SARS-CoV-2 virion identification in tissues: 

(i) Structures that
were spherical in 3D and not continuous with other adjacent structures with ~60-120 nM
diameters,
(ii) Spherical structures with densities corresponding to a distinct membrane bilayer,
internal puncta consistent with ribonucleoproteins, and densities corresponding to surface spikes
on the external peripheries of the spheres. Particles resembling virions were examined in 3D by
tomography prior to assignments (Supplementary Movies 1 and 2). We note that the inner
vesicles of multivesicular bodies (MVBs) have been mis-identified as SARS-CoV-2 by electron
microscopy. We therefore compared measurements of MVB inner vesicles and presumptive
coronavirus virions from what we identified as intracellular exit compartments within the same
tomogram (unpublished results) with our previous tomographic reconstructions of MVBs.
We distinguished virions inside a cytoplasmic exit compartment from the inner vesicles of an MVB based on differences in size (MVB inner virions are generally smaller in diameter than coronaviruses) and the presence of surface spikes and internal puncta (MVB inner vesicles do not present surface spikes or internal puncta).

**Cell Culture Experiments and Virus Isolation**

African green monkey kidney epithelial cells (Vero E6) were originally purchased from American Type Culture Collection (ATCC). Cells were maintained in Dulbecco's modified Eagle's medium (DMEM) w/ L-glutamate, sodium pyruvate (Corning) supplemented with 10% fetal bovine serum (FBS), 100 U penicillin/ml, and 100 mg streptomycin/ml. For all experiments, the cells were always maintained in monolayers.

Several attempts were made to isolate live infectious particles from these biopsies. Briefly, biopsies were collected and stored in PBS until homogenization. Following homogenization and centrifugation (10,000 × g, 20 min, 4°C), the resulting supernatant tissue supernatant was inoculated onto Vero E6 monolayer maintained in optimal virus growth media for SARS-CoV-2 virus (DMEM w/ L-Glutamate, Sodium Pyruvate, 2% FBS, 100 U Penicillin/ml, and 100 mg Streptomycin/ml, 10 mM Non-Essential Amino Acids, 1 mM Sodium Pyruvate and 10 mM HEPES). Vero E6 cells were incubated at 37 °C, 5% CO2 for a week and monitored daily for potential cytopathic effect (CPE).

Cell culture supernatants were also collected and assessed for the presence of infective particles by plaque assay. Briefly, ten-fold serial dilutions were performed in infection media for SARS-CoV-2 and inoculated onto confluent Vero E6 cell monolayer in 6-well plate. After one-hour adsorption, supernatants were removed, and cells monolayers were overlaid with minimum
essential media (MEM) containing 2% FBS and purified agar (OXOID) at a final concentration of 0.7%. Cells were then incubated for 3 days at 37°C. Cells were fixed overnight with 10% formaldehyde for the inactivation of potential SARS-CoV-2 virus. Overlay was removed and cells were washed once with PBS. A 2% crystal violet solution was used for plaque visualization and count. Experiments were performed under BSL3 conditions.

Viral SARS-CoV-2 RNA Detection in Intestinal Biopsy Tissue

To detect SARS-CoV-2 RNA from intestinal biopsies, a modified version of the CDC 2019-nCoV real-time RT-qPCR was used. Primers and probes were commercially available (Integrated DNA Technologies, cat. 10006713, RUO Kit). SARS-CoV-2 primer and probe sets consisted of two 2019-nCoV-specific sets (N1, N2). A third primer set was used to detect host cellular RNaseP. Reactions were run using the QuantiFast Pathogen RT-PCR +IC Kit (QIAGEN, cat. 211454). Assays were run using USA/WA-1/2020 SARS-CoV-2 RNA as a positive control and nuclease-free water as a non-template control in a 384-well format. A plasmid containing the genome sequence of the N protein (Integrated DNA Technologies, cat. 10006625, RUO Kit) was used to calculate genome copy number of from their respective CT (cycle threshold) using the linear equation from the respective plasmid standard curve. Limit of detection was established as 1-10 copies per µL. Reactions were performed in duplicate using the following cycling conditions on the Roche LightCycler 480 Instrument II (Roche Molecular Systems, 05015243001): 50°C for 20 min, 95°C for 1 sec, 95°C for 5 min, followed by 45 cycles of 95°C for 15 sec and 60°C for 45 sec. Limit of detection for SARS-CoV-2 was determined by using a commercially available plasmid control (Integrated DNA Technologies, cat. 10006625).
Biopsy collection and processing for Mass cytometry (CyTOF)

Biopsies were transferred to 10 ml of ‘dissociation buffer’ (1M HEPES(Lonza), 5μM EDTA(Invitrogen), 10% FBS in HBSS buffer (Gibco)). The tubes were kept in a shaker (180 rpm, 37°C) for 20 min and then gently vortexed. Cell suspensions were collected after passing the biopsies through 100μm cell strainers. A second round of EDTA dissociation was performed as detailed above. The cell suspension was centrifuged at 1800 rpm to pellet the epithelial fraction and kept on ice. The remaining tissue was transferred to fresh tubes containing a ‘digestion buffer’ (2% FBS, 0.005g Collagenase type IV per sample (Sigma), 100 μl DNAse-I (Sigma) in RPMI). Tubes were placed in the shaker (180 rpm, 37°C) for 40 min and thereafter gently vortexed. The digested tissues were filtered through 100 μm cell strainers followed by another round of filtration through 40μm cell strainers. Cell suspensions were centrifuged at 1800 rpm to obtain lamina propria mononuclear cells. Both epithelial cell (EC) and lamina propria (LP) pellets were then resuspended into 500 μl of RPMI (Gibco) containing 10% FBS+1μl Rh103 +1μl IdU and incubated at 37°C for 20 min. 5 ml RPMI (+10%FBS) was added to each tube and spun at 1800 rpm to pellet cells. 700 μl of Prot1 stabilizer (SmartTube Inc.) was added to each tube and transferred to cryovials and incubated at room temperature for 10 min. Cryovials were immediately transferred to -80°C until the sample was acquired for mass cytometry as detailed below.

Blood collection and processing for CyTOF

Briefly, 15ml of Lymphosep® - Lymphocyte Separation Medium (MP Bio.) was added to each 50 ml centrifugation tube. Blood was diluted with PBS to bring the volume up to 30ml and diluted blood was layered gently over Lymphosep®. Tubes were then centrifuged at 2000 rpm
for 20 mins with the brakes and acceleration off. After centrifugation, the buffy coat containing PBMCs was transferred to another tube and was centrifuged at 1800 rpm to pellet the cells. Pellets were resuspended in PBS and tubes were centrifuged at 1800 rpm. Finally, the pellets were resuspended in the freezing medium (10% DMSO + 44% FBS in RPMI) and cryopreserved at -80 °C.

**CyTOF processing and data acquisition**

Cells were processed as previously described by Geanon et al. Briefly, EC and LP SmartTube proteomic stabilized samples were thawed in a 10°C water bath and washed with Cell Staining Buffer (Fluidigm). To facilitate data acquisition and doublet removal, multiple samples were also barcoded using Fluidigm Pd barcoding kits and then washed and pooled for data acquisition. Immediately prior to data acquisition, samples were washed with Cell Staining Buffer and Cell Acquisition Solution (Fluidigm) and resuspended at a concentration of 1 million cells per ml in Cell Acquisition Solution containing a 1:20 dilution of EQ Normalization beads (Fluidigm). The samples were then acquired on a Helios Mass Cytometer equipped with a wide-bore sample injector at an event rate of <400 events per second. After acquisition, repeat acquisitions of the same sample concatenated and normalized using the Fluidigm software, and barcoded samples were de-multiplexed using the Zunder single cell debarcoder.

**CyTOF Data analysis**

De-barcoded files were uploaded to Cytobank for analyses. Immune cells were identified based on Ir-193 DNA intensity and CD45 expression; Ce140⁺ normalization beads, CD45-low/Ir-193-low debris and cross-sample and Gaussian ion-cloud multiplets were excluded from subsequent
downstream analysis. CyTOF antibody panel is detailed in Supplementary Data File 1. Major immune cell types were identified using automated Astrolabe approach, the result of which largely correlated well with our manual gating approaches. The impact of each tested condition on relative staining quality was evaluated in two ways: 1) overall correlations were determined by calculating the Pearson’s correlation coefficients for the median expression of each marker across each defined immune subset; and 2) a staining index was calculated using defined populations showing the highest and lowest expression levels of each marker: \( SI = (\text{Median}_{\text{pos}} - \text{Median}_{\text{neg}}) / 2 \times \text{Std.Dev}_{\text{neg}} \). It is already been described that SmartTube-based fixation protocols take into account previously described mass cytometry artifacts such as cell-cell multiplets, isotopic spillover or oxidation, or mass cytometer instrument configuration.

**Statistical Analysis for CyTOF**

Pre-gated viable CD45+ cells were first clustered and annotated using the Astrolabe Cytometry Platform (Astrolabe Diagnostics, Inc.), which involves using a hierarchy-based FlowSOM algorithm for labeling cell populations in individual samples. These Astrolabe Profiling clusters from each tissue type were then meta-clustered across all samples utilizing Clustergrammer2's interactive heatmap as a method to interrogate antibody expression across every cluster and curate and assign cell population categories. Single sample clusters were also visualized using UMAP. Pairwise comparisons were performed on the frequencies of each identified cell population between the patient cohorts (COVID-19 vs. control, COVID-19 severe vs. control, COVID19-asymptomatic/mild/moderate vs. control) to determine fold change, p-values and FDR adjusted p-values using the Benjamini-Hochberg method to account for multiple comparisons.
RNA Sequencing

Library preparation and sequencing

Directional RNA-seq libraries were prepared from 50 ng of total RNA from EC and LP samples with the TruSeq® Stranded Total RNA prep with Ribo-Zero kit (Cat no. 20020599). Paired-end (100 bp) sequencing was performed for DNA libraries on an Illumina NovaSeq instrument on a NovaSeq S1 Flowcell, with an average yield of 39 million PE reads/sample.

RNA-seq analysis

Base-calling and quality scoring of sequencing data were done through Illumina’s Real-Time Analysis (RTA) software. RNA-seq data processing and reference mapping were done with custom analysis scripts combining publicly available tools as previously described with modifications as follows, reads were mapped to a custom reference that combined the human hg38 reference genome (Release 34, GRCh38.p13) and the SARS-CoV-2 genome (RefSeq NC_045512) for simultaneous quantification of host and virus transcripts.

Differential gene expression (DGE) analysis was performed with the Bioconductor edgeR package using as input a combined matrix of mapped paired-end read raw counts, with genes in rows and samples in columns. Prior to DGE analysis, gene counts were converted to fragments per kb per million reads (FPKM) with the RSEM package with default settings in strand-specific mode.

Genes with less than 1 FPKM in at least 50% of the samples were removed. The remaining gene counts were then normalized across samples using the weighted trimmed mean of M-values (TMM) method. The dispersion was estimated by fitting a generalized linear
model (GLM) as implemented in edgeR, sex was fitted as a covariate on a per-patient paired design. Pairwise comparisons were performed between sample groups (i.e., between tissue sections, and between cases and controls). Significant expression differences were selected based on eBayes adjusted p values corrected for multiple testing using the Benjamini-Hochberg method (q ≤ 0.05).

**Gene Ontology and Pathway Enrichment Analysis**

KEGG pathway and gene ontology (GO) biological process (BP), molecular function (MF), and/or cellular component (CC) enrichment analyses were performed using the gProfileR R v0.6.8 package\(^\text{19}\). The background gene set was restricted genes with detected expression (defined as genes with expression levels above 1 FPKM in at least 50% of samples). Genes with differential expression were ranked by log 2 fold change and used as an ordered query. P values were corrected using the g:SCS algorithm to account for multiple comparisons.

**Cell-type deconvolution and gene signature enrichment analysis**

For cell-type deconvolution of the bulk RNA-seq data, Gene Set Enrichment Analysis (GSEA) of differentially expressed genes of cases vs controls comparisons was performed against cell type gene-expression single-cell signatures from intestinal mucosa\(^\text{20}\) and gene-expression signatures from ileal dendritic cell (DCs) subsets\(^\text{21}\). Similarly, differentially expressed genes were tested for enrichment of gene signatures associated with an antiviral response, inflammation, and cytokine signaling in acutely infected post-mortem tissue with SARS-CoV-2\(^\text{22}\), were tested for significant (p ≤ 0.05) enrichment using Fisher’s exact tests and using Bonferroni correction for multiple comparisons.
Additionally, GSEA23 was carried out on a rank ordered list of the infected EC versus control molecular analysis. The ranking metric used was logFC * -logP value, however, the results were similar when logFC metric was also used (data not shown). For the COVID-19 associated datasets, we curated two signatures from infected organoids: hSIOs-COVID-19: human small intestinal organoids (hSIOs) grown in either i) Wnt high expansion (EXP) medium (at adjP<0.05) or ii) differentiation (DIF) medium (at adjP<0.1). The standard GSEA settings were used, namely ‘meandiv’ for normalization mode, ‘weighted’ enrichment statistic, and ‘1000’ permutations. GSEA using the Hallmark database (v7.125) was also performed with the same settings.

**Computational analyses**

*Multivariate model based on Discovery Cohort*

For this analysis, we considered 570 patients with clinical descriptors including as age, gender, race/ethnicity, BMI, comorbidities (including hypertension, diabetes, chronic lung disease (including asthma and COPD), heart disease (including coronary artery disease, atrial fibrillation and heart failure), and GI symptoms. A multivariate logistic regression was utilized to model severity and mortality as function of each of the GI symptoms and clinical variables including race, age, gender, BMI, heart and lung diseases and hypertension.

In particular, race was stratified as White (Caucasian), Black (African-American), Hispanic and others; lung disease was set equal to 1 if the patient was either affected by COPD or asthma and zero otherwise; heart disease was set equal to 1 if the patient was either affected by coronary artery disease, atrial fibrillation or heart failure and 0 otherwise. The severity indicator was set equal to 1 for severe and severe with EOD patients and 0 for mild and moderate COVID-19 patients; mortality was set equal to 1 for deceased patients and 0 otherwise.
Significant association were determined based on 95% confidence interval (CI) based on 1000 bootstrap iterations. At each bootstrap iteration, patients were sampled with replacements and logistic regressions were estimated considering as outcome severity and mortality. Then, 95% CI of coefficients and odds ratio were estimated across bootstrap iterations.

**External Validation Cohort**

For this analysis, we considered 228 patients with clinical data such as age, gender and GI symptoms as described in Aghemo et al. A multivariate logistic regression was utilized to model mortality, ICU admission and the composite outcome of ICU admission or mortality as function of presence or absence of diarrhea and clinical variables including age, gender, BMI, heart disease, COPD, diabetes and hypertension. Heart disease was set equal to 1 if the patient was either affected by coronary artery disease or atrial fibrillation and 0 otherwise. CI of odds ratio were computed based on 1000 bootstrap iterations as above.

In 270 patients from this cohort treatment data was available. Treatments included hydroxychloroquine, antiviral treatments including lopinavir-ritonavir and darunavir-cobicistat, tocilizumab, steroids, antibiotics including ceftriaxone, azithromycin, piperacillin-tazobactam, statins, angiotensin-converting-enzyme (ACE) inhibitors and angiotensin II receptor blockers (ARBs). Using this data, we performed fisher’s exact test to determine whether any treatments were associated with diarrhea. Additionally, we computed 95% CI of odds ratio based on 1000 bootstrap iterations.

*Predictive performance based on the Internal Validation Cohort*
For this analysis, we considered 233 patients with clinical data including age, BMI, and GI symptoms. In order to evaluate the predictive performance of each model, bootstrapping was performed. Specifically, at each bootstrap iteration, we randomly sampled patients in the Discovery Cohort with replacement and estimated a logistic regression to model each outcome as function of a particular GI symptom, age and BMI. In this analysis, only age and BMI were adjusted for since they were the only variables significantly associated with both outcomes across different GI symptoms models in the Discovery Cohort (Figure 5B, Supplementary Table 9). Then, the estimated model was utilized to predict the outcome of patients in the Internal Validation Cohort. This procedure was repeated for 1000 bootstrap iterations. For each iteration, Receiving Operating Characteristic (ROC) curve and area under the curve (AUC) were computed. For comparison purposes, the distribution of AUC across 1000 bootstrap iterations from the predictive model based on age and BMI only was considered. Figure 5D shows the boxplot of AUC values across 1000 bootstrap iterations. Then, considering the following model

\[
\text{outcome} = f(\text{age} + \text{bmi} + \text{any GI symptom}) \ [\text{Model 1}]
\]

we evaluated the effect of each variable on the outcome by computing the reduction in AUC obtained after removing one variable at a time. For this purpose, the AUC of model [Model 1] was compared to the following three models

\[
\text{outcome} = f(\text{age} + \text{bmi}) \ [\text{Model 2}]
\]

\[
\text{outcome} = f(\text{age} + \text{any GI symptom}) \ [\text{Model 3}]
\]

\[
\text{outcome} = f(\text{bmi} + \text{any GI symptom}) \ [\text{Model 4}]
\]

for 1000 bootstrap iterations. Following the strategy above, at each bootstrap iteration, patients were sampled with replacement. Figure 5E shows the 95% confidence intervals of difference in AUC between [Model 1] and [Model 2], [Model 3] and [Model 4] (i.e., \(\text{AUC}_{\text{Model 1}} - \text{AUC}_{\text{Model 2}}\)...)
AUCModel2, AUCModel1 - AUCModel3, AUCModel1 - AUCModel4) across 1000 bootstrap iterations. The difference in AUC was computed considering both mortality and severity as the outcome.

**Average treatment effect (ATE)**

The average treatment effect (ATE) for the Mount Sinai Cohort (MSH) combining Discovery and Internal Validation Cohorts and the External Validation Cohort were calculated via the TMLE package in R\(^2\)\(^6\). For the MSH cohort, ATE was calculated for each GI symptom using as outcomes disease severity and mortality. The marginal effect was calculated after adjusting for covariates such as age, race, BMI, gender, diabetes, lung disease, heart disease and hypertension. For the External Validation Cohort, ATE was calculated for diarrhea on ICU admission, mortality and the composite of ICU admission and mortality. The marginal effect was calculated after adjusting for covariates such as age, BMI, gender, diabetes, lung disease, heart disease and hypertension.

**Quantification of SARS-CoV-2 nasopharyngeal viral loads**

SARS-CoV-2 viral loads were determined as detailed in Pujadas et al\(^2\)\(^7\). Briefly, viral RNA was extracted from the NP swab specimen followed by real time RT-PCR using N2 primers. Only specimens with \(N2_{\text{C}_{\text{PT}}} < 38\) were included. SARS-CoV-2 viral RNA was calculated with the delta CT method and a standard curve. Viral loads are presented as log base 10 transformed uncorrected N2 value + 1000 (constant added before transformation)\(^2\)\(^7\). For patients with multiple NP swabs available, the first swab was used for analysis.

**ELLA Cytokine panel**
The ELLA platform is a method for rapid cytokine measurement using microfluidics ELISA assays. The assay measured TNF-α, IL-6, IL-8, and IL-1β, previously validated by the Mount Sinai Human Immune Monitoring Center (HIMC) using plasma from multiple myeloma patients and recently reported for large cohort of COVID-19 patients admitted to MSH.

**Multiplexed proteomic assay (Olink)**

For analysis of circulating cytokines, we used a multiplexed proteomic inflammation panel (Olink), which consists of 92 inflammation-related proteins quantified by an antibody-mediated proximity extension-based assay. Samples with normalized protein expression values below the limit-of-detection in >75% of samples were excluded from further analysis. For the remainder of analytes, any sample under the limit of detection was assigned a value of the limit-of-detection divided by the square root of 2. The log2 fold-change over the median healthy control protein expression was then calculated, and the Benjamini-Hochberg procedure was used to adjust P values for multiple testing.

**Consensus Clustering of Olink Data**

For this analysis, we considered 238 samples with GI symptoms annotation. Consensus clustering was performed based on the abundance of 92 cytokines across all 238 samples. Consensus clustering was performed using the R packages ConsensusClusterPlus based on z-score normalized data. Specifically, markers were partitioned into six clusters using the K-means algorithm, which was repeated 1000 times. Then, markers in each cluster were considered in order to derive cluster z-score signatures via package GSVA. Based on these signatures, the association between different clusters and GI symptoms were derived via logistic regression with
outcome corresponding to each GI symptom. Figure 6C shows the signed FDR (-log10 scale). P-values were adjusted via Benjamini-Hochberg. The pathway analysis for the clusters described above was carried out considering the entire KEGG and HALLMARK databases.

Supplementary Figures and Tables

Supplementary Figure 1. Sample allocation for different assays in COVID-19 patients and controls. Venn diagrams showing blood and biopsy samples used for mass cytometry (#) and RNA sequencing (Δ) in COVID-19 patients (red) and controls (blue). The numbers in the Venn diagrams refer to respective patient and control cases detailed Supplementary Table 2. The table summarizes the total number of blood and biopsy samples allocated for mass cytometry and RNA sequencing.
Supplementary Figure 2. Representative H&E staining of small intestinal biopsies of COVID-19 patients. Patient number in the top left corner corresponds with the patient number in Supplementary Table 2. All biopsies are duodenal with the exception of patient 12 which is from the terminal ileum. Scale bar; 100µm.
Supplementary Figure 3. Intraepithelial lymphocytes (IELs) are not increased in small intestinal biopsies from COVID-19 patients compared to controls. (A) CD3+ and CD8+ IELs per mm of epithelium in COVID-19 patients and uninfected controls in the duodenum (black) and ileum (gray). P-values generated from unpaired t-tests. (B) Representative IF images of small intestinal biopsies showing CD3 (green), CD8 (red) and DAPI (blue). Representative CD8+ IELs (arrow head) and representative CD8- IELs (arrow) are indicated. Scale bar; 100µm.
Supplementary Figure 4. Representative immunofluorescence (IF) images of small intestinal biopsies of COVID-19 patients. SARS-CoV-2 nucleocapsid (green), EPCAM (red) and DAPI (blue) in all COVID-19 patients where tissue was available for IF. Patient number in the top right corner corresponds with the patient number in Supplementary Table 2. All biopsies are duodenal with the exception of patient 12 which is from the terminal ileum. Patient 8 missing due to technical difficulties during IF staining. Scale bar; 100 µm.
Supplementary Figure 5. Representative immunofluorescence images of small intestinal biopsies of control patients. SARS-CoV-2 nucleocapsid (green), EPCAM (red) and DAPI (blue) in duodenal biopsies (upper) and ileal biopsies (lower). Scale bar; 100 µm.
Supplementary Figure 6. Electron microscopy by high pressure freezing/freeze substitution fixation (HPF/FSF) of presumptive SARS-CoV-2 infection in culture Vero cells. (A) Montaged overview of an infected cell (150 nm section) (presented for comparison with analogous structures found in tissue samples (Figure 2 and Supplementary Movie 1), which could not be preserved under similar optimal conditions for EM). The cell exhibits large numbers of cytoplasmic vacuoles, surface blebbing and general cytopathogenicity. (B) Montaged tomographic reconstruction of the central portion of the cell shown in A. Large numbers of
presumptive SARS-CoV-2 virions are contained within cytoplasmic compartments, most are closely adjacent to the compartment’s peripheries. (C) Gallery of 30 individual presumptive SARS-CoV-2 virions taken from the tomogram shown in B. Each example is displayed as an equatorial view with a tomographic thickness of 4.7 nm.
Supplementary Figure 7. Altered immune populations in the lamina propria of COVID-19 patients compared to controls. (A) Relative frequencies of lamina propria immune cells in controls and COVID-19 patients. Open red circles denote patients with asymptomatic/mild/moderate disease while filled red circles denote patients with severe COVID-19. The bar plots show median frequencies. (B) The stacked bar graphs show the distribution of average frequencies of naïve and memory CD4+ and CD8+ T cells in the lamina propria of COVID-19 patients and controls.
Supplementary Figure 8. Altered immune populations in the epithelial compartment (EC) of COVID-19 patients compared to controls. (A) The heat map shows clustering and distribution of different cell types in the EC. Relative frequencies of (B) intraepithelial lymphocytes (IELs) and (C) plasma cells in the EC of controls and COVID-19 patients. Open red circles denote patients with asymptomatic/mild/moderate disease while filled red circles denote patients with severe COVID-19. The bar plots show median frequencies.
Supplementary Figure 9. Altered immune populations in the blood of COVID-19 patients compared to controls. (A) The heat map shows clustering and distribution of different immune cell types in the blood. Relative frequencies of (B) classical (dotted bars) and non-classical monocytes (open bars), (C) CD4+ regulatory T cells and (D) IgG+ plasma cells in the blood of controls and COVID-19 patients. Open red circles denote patients with asymptomatic/mild/moderate disease while filled red circles denote patients with severe COVID-19. The bar plots show median frequencies.
Supplementary Figure 10. Altered T cell populations in blood and intestinal biopsies of COVID-19 patients compared to controls based on supervised analysis. Representative CyTOF plots and bar plots comparing the frequencies of CD29+ CD38+ CD4+ and CD29+ CD38+ CD8+ T cells in (A) the blood and (B) lamina propria of controls (blue) and COVID-19 patients (red). Open red circles denote patients with asymptomatic/mild/moderate disease while filled red circles denote patients with severe COVID-19. The bar plots show median frequencies.
Supplementary Figure 11. Distinct expression profiles in the intestinal epithelial compartment (EC) and lamina propria (LP). (A) Principal Component Analysis (PCA) of EC and LP fractions of COVID-19 patients and controls. The two tissue fractions separate on the principal component 1 (x-axis). (B) Hierarchical clustering of average expression changes for 6636 genes (rows) characterizing the EC (red) or LP (blue) fractions (FDR ≤ 0.05) in the intestinal biopsies of COVID-19 patients and controls. The left panel indicates significant genes in yellow for each tissue compartment. The color bar (right panel) indicates the average log2 fold-change (FC).
Supplementary Figure 12. Immune signatures in the epithelial compartment (EC) of COVID-19 patients. Gene Set Enrichment Analysis (GSEA) was performed using a rank ordered list of genes differentially expressed in the infected EC vs control EC. The metric for ranking was logFC*-logPvalue. (A) GSEA was performed on the rank ordered EC gene set using SARS-CoV-2 infected organoid datasets. The gene sets tested were molecular signatures curated...
from SARS-CoV-2 infected organoid experimental datasets using human small intestinal organoids (hSIOs) grown in either i) Wnt high expansion (EXP) medium (at adjP < .05) or ii) differentiation (DIF) medium (at adjP < .1). Only gene sets significantly enriched (at FDR <0.05) are displayed. (B) GSEA was performed for the same rank ordered EC gene set using the Hallmark Pathway datasets. Two significantly enriched pathways were found to be associated with upregulated genes in infected EC relative to controls (at FDR<0.05). Normalized enrichment score (NES) and FDR values are as indicated.
**Supplementary Figure 13. Flow diagram of the Discovery Cohort.** The diagram shows the total number of patients admitted to the Mount Sinai Health System between April 1-15, 2020 and the selection process that was adopted in order to select patients in the Discovery Cohort.
Supplementary Figure 14. Nausea and vomiting were associated with reduced mortality and severity. Kaplan-Meier curves for mortality stratified by (A) nausea and (B) vomiting for patients in the Discovery Cohort. $P$-values from log-rank test and 95% confidence intervals of Kaplan-Meier curves are shown. Below each Kaplan-Meier, the number of patients at risk for different time points are reported.
Supplementary Figure 15. COVID-19 patients with GI symptoms had reduced levels of circulating IL-6 and IL-8. (A) IL-6, (B) IL-8, (C) TNF-α and (D) IL-1β at the time of admission in patients with and without GI symptoms. Boxplots represent the median and interquartile range. $P$-values calculated using unpaired two-tailed t-test.
Supplementary Figure 16. Correlation matrix (Pearson’s) for 92 markers contained in the Olink platform. (A) Correlation matrix across patients with nausea (left panel) compared to patients without nausea (right panel); and (B) patients with vomiting (left panel) compared to patients without vomiting (right panel). Cluster assignment derived using unsupervised consensus clustering is reported on the top of the heatmap.
**Supplementary Table 1. Biopsy cohort characteristics**

| Characteristic                                      | COVID-19 biopsy cases (n = 19) | Uninfected controls (n=10) | p-value |
|-----------------------------------------------------|-------------------------------|-----------------------------|---------|
| Age (mean years ± std* )                            | 54 ± 20                       | 65 ± 11                     | 0.12    |
| Male sex                                            | 12 (63%)                      | 5 (50%)                     | 0.69    |
| Number of comorbidities §                           | 1.9 ± 1.6                     | 2.0 ± 1.1                   | 0.93    |

|            | Survivor   | 206         | 277         |         |
| Any GI symptoms | Non-survivor | 47       | 104        | <0.0001 |
|            | Survivor   | 252         | 231         |         |
Supplementary Table 8. Basic demographics in survivors and non-survivors in the Discovery Cohort. For age, the mean ± standard deviation and an unpaired two-tailed t-test was performed. For categorical variables, the number of patients followed by the percent of patients in parentheses is listed and the Fisher’s exact test or the Chi-square test was used as appropriate.

| Survivors (n=483) | Non-survivors (n=151) | p-value |
|-------------------|-----------------------|---------|
| Age (years)       | 61.3 ± 15.2           | 72.6 ± 14.1 | <0.0001 |
| Male              | 287 (59.4)            | 82 (54.3)  | 0.30    |

Disease severity

|        | Survivors (n=483) | Non-survivors (n=151) | p-value |
|--------|-------------------|-----------------------|---------|
| Mild   | 48 (9.9)          | 6 (4.0)               |         |
| Moderate | 318 (65.8)       | 43 (28.5)             |         |
| Severe | 95 (19.7)         | 63 (41.7)             | <0.0001 |
| Severe with EOD | 22 (4.6)  | 39 (25.8)             |         |

| Rabbit IgG H&L | Polyclonal | Abcam  | ab150077       | goat    | Alexa Fluor 488 | 1:1000 |

**Supplementary Movie 1.** Montaged tomographic reconstruction of Golgi region of a goblet cell in apical epithelium of the terminal ileum of a COVID-19 patient. The movie begins with an overview of the goblet cell Golgi complex within a reconstructed volume of a 150 nm section. Intestinal epithelial cells border the goblet cell on the left and right side, and the apical portion of the epithelium is in the upper right, outside of the field of view. The movie progressively zooms
in to detail a membrane-bound compartment located at the trans-side of the Golgi stack. This compartment contains five presumptive SARS-CoV-2 virions that closely resemble the structures illustrated in Supplementary Figure 6 and in similar datasets of presumptive SARS-CoV-2 virions in SARS-CoV-2 infected cultured cells in Supplementary Movie 2.

**Supplementary Movie 2.** Tomographic reconstruction of SARS-CoV-2–infected cultured cells, prepared by high-pressure freezing and freeze-substitution fixation. The movie, which is presented for comparison with analogous structures found in tissue samples (Figure 2 and Supplementary Movie 1) that could not be preserved under similar optimal conditions, shows an overview of a central portion of an infected cell, featuring large numbers of presumptive SARS-CoV-2 virions within membrane-bound compartments, and then increases in magnification to show details of groups of presumptive virions and then individual presumptive virions themselves. Note the consistent presence of dense nucleocapsid puncta arranged within the core of each presumptive virion, membrane bilayers, and occasional surface spike densities visible through the volume.
