COORDINATE NEIGHBORHOODS OF ARCS AND THE APPROXIMATION OF MAPS INTO (ALMOST) COMPLEX MANIFOLDS

DEBRAJ CHAKRABARTI

ABSTRACT. We study the approximation of $J$-holomorphic maps continuous to the boundary from a domain in $\mathbb{C}$ into an almost complex manifold by maps $J$-holomorphic to the boundary, giving partial results in the non-integrable case. For the integrable case, we study arcs in complex manifolds and establish the existence of neighborhoods biholomorphic to open sets in Euclidean space for several classes of arcs. As an application we obtain $C^k$ approximation of holomorphic maps continuous to the boundary into complex manifolds by maps holomorphic to the boundary, provided the boundary is nice enough.

1. Introduction

This paper is divided into three sections, which though mostly independent of each other, are devoted to the study of the following question: let $\Omega \subset \mathbb{C}$, and let $(X, J)$ be an almost complex manifold. Suppose that $f$ is a continuous map from the closure $\overline{\Omega}$ to $X$ which is $J$-holomorphic on $\Omega$. Can we approximate $f$ by maps $J$ holomorphic on (shrinking) neighborhoods of $\overline{\Omega}$?

In Section 2 we give some conditions under which such a map $f$ can be approximated by $J$-holomorphic maps in a neighborhood of $\overline{\Omega}$. Unfortunately this involves smoothness assumptions on the boundary $\partial \Omega$ and on $f$ as well (see Theorem 1 below.)

As might be expected, when the almost complex structure $J$ is integrable, we can say much more, since we have the tools of Complex Analysis at our disposal. In fact, recently Drinovec-Drnovšek and Forstnerič have proved the following: Let $S$ and $X$ be complex manifolds, and let $\Omega \subset S$ be a strongly pseudoconvex Stein domain with boundary of class $C^k$ with $k \geq 4$. Then every $C^{k-2}$ map from $\overline{\Omega}$ to $X$ can...
be approximated in the $C^{k-2}$ sense by maps which are holomorphic on (shrinking neighborhoods of) $\Omega$ (see Theorem 2.1 in [5]). This is a consequence of the fact that the graph of such maps have a basis of Stein neighborhoods (Theorem 2.6 in [5].) In a forthcoming paper, they have been able to drop the smoothness assumption on the map to be approximated, and avoid the construction of Stein neighborhoods by use of the theory of sprays. In this paper, we consider the case in which the source manifold $S$ is the complex plane $\mathbb{C}$, for which we give a proof along completely different lines, and in the way obtain some results of interest on their own.

Section 3 is devoted to the study of arcs (injective continuous maps from the interval) in complex manifolds. We ask the following question: under what circumstances does such an arc have a coordinate neighborhood, i.e. a neighborhood biholomorphic to an open set in Euclidean space $\mathbb{C}^n$? For a real analytic arc $\alpha$ embedded in a complex manifold $\mathcal{M}$ (i.e., for each $t \in [0,1]$ we have $\alpha'(t) \neq 0$), it is an old result of Royden that a coordinate neighborhood exists (see [14]). We show that embedded $C^2$ arcs as well as $C^1$ arcs with some additional conditions have coordinate neighborhoods (see Proposition 3.8 and Proposition 3.3.) For our application it is important not to restrict attention to smooth arcs alone. We consider a class of non-smooth arcs with finitely many non-smooth points which we call mildly singular (see Definition 3.4 below.) We show that such arcs have coordinate neighborhoods (Theorem 2).

As an easy consequence of the results of Section 3 in Section 4 we obtain the following result, a special case of the results of Drivonec-Drovšnek and Forstnerič (with slightly weaker hypothesis on than theirs on the boundary):

*Let $k \geq 0$ be an integer and let $\mathcal{M}$ be an arbitrary complex manifold. Let $f$ be a $C^k$ map from $\Omega$ into $\mathcal{M}$, where the open set $\Omega \subseteq \mathbb{C}$ is bounded by finitely many Jordan curves, which are further assumed to be $C^1$ if $k \geq 1$. If $f$ is holomorphic on $\Omega$, it can be approximated in the $C^k$ topology by holomorphic maps from (neighborhoods of) $\Omega$ into $\mathcal{M}$."

This paper is based on the author’s Ph. D. thesis [3]. He would like to take this opportunity to express his deepest gratitude to his advisor, Prof. Jean-Pierre Rosay. Without his constant encouragement and help neither the thesis and nor this paper would ever have been written.
2. Maps into almost complex manifolds

We begin by introducing some notation. For a compact $K \subset \mathbb{R}^N$, an integer $k \geq 0$ and $0 < \theta < 1$, let $C^{k,\theta}(K)$ denote the Lipschitz space of order $k + \theta$, denoted by $\text{Lip}(k + \theta, K)$ in the text [15], where it is defined as a Banach space of $k$-jets, with $k$-th derivatives Hölder continuous with exponent $\theta$. If the set $K$ is nice, for example the closure of a smooth domain (which will always be the case in our applications), we can identify $C^{k,\theta}(K)$ with the space of those $k$ times differentiable functions on $K$ all whose partial derivatives of order $k$ are Hölder continuous with exponent $\theta$. The following remarkable fact is proved in [15](p.177, Theorem 4.)

**Lemma 2.1.** Given $N, k \in \mathbb{N}$ and $0 < \theta < 1$, there is a constant $C$ with the following property. Given any compact $K \subset \mathbb{R}^N$, there is a linear extension operator $E : C^{k,\theta}(K) \rightarrow C^{k,\theta}(\mathbb{R}^N)$ such that $\|E\|_{\text{op}} < C$.

For a Riemannian manifold $(X, g)$, we define the space $C^{k,\theta}(K, X)$ of Lipschitz maps in the obvious way using local charts on $X$, and this space has a natural structure of a metric space. Observe however that the topology on $C^{k,\theta}(K, X)$ is not dependent on the choice of the metric $g$.

Let $(X, J)$ be an almost complex manifold, where we assume that the almost complex structure $J$ is of class $C^{k,\theta}$ for some $k \geq 1$ and $0 < \theta < 1$. For compact $K \subset \mathbb{C}$, we denote by $\mathcal{H}_J(K, X)$ the space of $J$-holomorphic maps from $K$ to $X$. The map $f : K \rightarrow X$ belongs to $\mathcal{H}_J(K, X)$, iff for some open $U_f \supset K$, the map $f$ extends $J$-holomorphically to $U_f$. It is well known that $\mathcal{H}_J(K, X) \subset C^{k+1,\theta}(K, X)$. Let $\mathcal{A}_J^{k,\theta}(K, X)$ denote the closed subspace of $C_J^{k,\theta}(K, X)$ consisting of maps $f$ which are $J$-holomorphic on the interior of $K$.

We can now state the following:

**Theorem 1.** Let $(X, J)$ be an almost complex manifold with the structure $J$ of class $C^{k,\theta}$, where $k \geq 1$ and $0 < \theta < 1$, and let $\Omega$ be an open set in $\mathbb{C}$ with $C^1$ boundary. Then in the metric space $C^{k,\theta}(\overline{\Omega}, X)$, the set $\mathcal{H}_J(\overline{\Omega}, X)$ is dense in the set $\mathcal{A}_J^{k+1,\theta}(\overline{\Omega}, X)$.

First we prove a slightly stronger version (Proposition 2.3) for $X = \mathbb{R}^{2n}$, and then reduce the general case of an a.c. manifold $X$ to it.
Lemma 2.2. Let $k \geq 1$ be an integer, $\omega \subset \mathbb{C}$ an open set, and $B$ a $2n \times 2n$ real matrix of $C^{k-1,\theta}$ functions on $\overline{\omega}$. Let $L$ denote the differential operator given by

$$L(h) = \frac{\partial h}{\partial \overline{z}} + Bh,$$

mapping $C^{k,\theta}(\overline{\omega})$ into $C^{k-1,\theta}(\overline{\omega})$. There exists a constant $C_0$ such that for any open subset $W \subset \omega$, and any $g \in C^{k-1,\theta}(\overline{W})$ there exists $h \in C^{k,\theta}(\overline{W})$ such that, on $W$,

$$Lh = g$$

and

$$\|h\|_{C^{k,\theta}(\overline{W})} \leq C_0 \|g\|_{C^{k-1,\theta}(\overline{W})}.$$

Proof. Fix $R > 0$ such that $\omega \subset \Delta_R = \{ z \in \mathbb{C} : |z| < R \}$. By Theorem A2 of \cite{13}, one can solve the equation

$$\frac{\partial \tilde{h}}{\partial \overline{z}} + B\tilde{h} = \tilde{g}$$

on $\Delta_R$ with $\|\tilde{h}\|_{C^{k,\theta}(\Delta_R)} \leq K_R \|\tilde{g}\|_{C^{k-1,\theta}(\Delta_R)}$, where $K_R$ is a constant depending only on $R$. (The proof in \cite{13} assumes that $k = 1$, but it generalizes immediately)

Let $C$ be the absolute constant provided by Lemma 2.1 as an upper bound to the norm of linear extension operators mapping $C^{k-1,\theta}$ of a compact subset of $\mathbb{R}^2$ to $C^{k-1,\theta}(\mathbb{R}^2)$. Extend the data $g$ and the coefficients $B$ of equation (\ref{eq:21}) from $\overline{W}$ to $\tilde{g}$ and $\tilde{B}$ defined on $\mathbb{R}^2$, with $\|g\|_{C^{k-1,\theta}(\mathbb{R}^2)} \leq C \|g\|_{C^{k-1,\theta}(\overline{W})}$, and similarly for $B$. We now solve equation (\ref{eq:21}) with estimates as mentioned above, and set $h$ to be the restriction of $\tilde{h}$ to $\overline{W}$. \hfill \Box

We now prove a version of Theorem 1 for $X = \mathbb{R}^{2n}$.

Proposition 2.3. Let $\Omega \subset \mathbb{C}$ be an open set and let $U$ be an open neighborhood of $\overline{\Omega}$. Let $J$ be an almost complex structure of class $C^{k,\theta}$ on $\mathbb{R}^{2n}$, with $k \geq 1$. Let $\beta$ be such that $\theta < \beta < 1$. Suppose that the $C^{k,\beta}$ map $f : \overline{U} \to \mathbb{R}^{2n}$ is such that

- $f|_\Omega$ is $J$-holomorphic, and
- $J|_{f(\Omega)} = J_{st}$, the standard complex structure of $\mathbb{R}^{2n} = \mathbb{C}^n$.

Then $f$ can be approximated uniformly on $\overline{\Omega}$ by $J$-holomorphic maps.

Proof. Suppose we are given $\epsilon_0 > 0$. We want to find a neighborhood $\Omega_{\epsilon_0}$ of $\overline{\Omega}$, and a $J$-holomorphic $u$ from $\overline{\Omega_{\epsilon_0}}$ into $\mathbb{R}^{2n}$ such that $\|u - f\|_{C^{k,\beta}(\overline{\Omega_{\epsilon_0}})} < \epsilon_0$. 

We set
\[
\frac{\partial u}{\partial z} = \frac{1}{2} \left( \frac{\partial u}{\partial x} + J_{st} \frac{\partial u}{\partial y} \right)
\]
and
\[
\frac{\partial u}{\partial \bar{z}} = \frac{1}{2} \left( \frac{\partial u}{\partial x} - J_{st} \frac{\partial u}{\partial y} \right)
\]
since \( J_{st} \) corresponds to multiplication by \( i \) in the identification of \( \mathbb{R}^{2n} \) with \( \mathbb{C}^n \). We know that, provided that \( J + J_{st} \) is invertible, the condition that a map \( u \) from some subset of \( \mathbb{C}^n \) into \( (\mathbb{R}^{2n}, J) \) is \( J \)-holomorphic is given by
\[
\Phi(u) := \frac{\partial u}{\partial z} + Q(u) \frac{\partial u}{\partial \bar{z}} = 0
\]
where \( Q(u) \) is a \( 2n \times 2n \) matrix, given by
\[
Q(u) = \left[ J(u) + J_{st} \right]^{-1} \left[ J(u) - J_{st} \right].
\]
Since \( J = J_{st} \) on the range of \( f \), for maps \( u \) sufficiently close to \( f \), we have \( J(u) \approx J_{st} \), so this equation determines the \( J \)-holomorphy of \( u \) for such maps.

We will think of \( \Phi \) to be a map from \( C^{k,\theta}(\overline{U}) \) to \( C^{k-1,\theta}(\overline{U}) \). Its derivative is given by:
\[
\Phi'(u)h = \frac{\partial h}{\partial z} + Q(u)h \frac{\partial u}{\partial \bar{z}} + Q(u)h \frac{\partial h}{\partial \bar{z}} = \left\{ \frac{\partial h}{\partial z} + A(u)h \right\} + Q(u)h \frac{\partial h}{\partial \bar{z}} = L_u h + R_u h.
\]
(3)

Observe that \( A \) and \( Q \) are \( 2n \times 2n \) matrices with entries in \( C^{k-1,\theta}(\overline{U}) \) and \( C^{k,\theta}(\overline{U}) \) respectively. Since we can easily show that the assignments \( u \mapsto (h \mapsto A(u)h) \) and \( u \mapsto (h \mapsto Q(u)h_z) \) are continuous from \( C^{k,\theta}(\overline{U}) \) into the Banach space of operators \( BL(C^{k,\theta}(\overline{U}, \mathbb{R}^{2n}), C^{k-1,\theta}(\overline{U}, \mathbb{R}^{2n})) \), it follows that \( \Phi \) is \( C^1 \).

We claim the following: There is an open \( W \supset \overline{\Omega} \) such that \( \Phi'(f) \) is surjective from \( C^{k,\theta}(\overline{W}) \) to \( C^{k-1,\theta}(\overline{W}) \).

To prove the claim, observe that \( Q(f) \in C^{k,\theta} \), therefore, a fortiori \( Q(f) \) is in \( C^k \). We can choose \( W \supset \Omega \) so small that \( \|Q(f)\|_{C^k(\overline{W})} \) is small. Since the boundary \( \partial \Omega \) of the set \( \Omega \) is \( C^1 \) by hypothesis, we can also choose the \( W \) such that the \( C^{k-1,\theta} \) norm is dominated by the \( C^k \) norm. Therefore, we can find a \( W \) such that
\[
\|Q(f)\|_{C^{k-1,\theta}(\overline{W})} < \frac{1}{2C_0 K},
\]
where $C_0$ is the constant in Lemma 2.2 above. Therefore we have for $h$ in $C^{k,\theta}(\overline{W})$:

$$
\| R_f h \|_{C^{k-1,\theta}(\overline{W})} = \left\| Q(f) \frac{\partial h}{\partial \overline{z}} \right\|_{C^{k-1,\theta}(\overline{W})} \\
\leq \|Q(f)\|_{C^{k-1,\theta}(\overline{W})} \left\| \frac{\partial h}{\partial \overline{z}} \right\|_{C^{k-1,\theta}(\overline{W})} \\
\leq \|Q(f)\|_{C^{k-1,\theta}(\overline{W})} \|h\|_{C^{k,\theta}(\overline{W})} \\
< \frac{1}{2C_0K} \|h\|_{C^{k,\theta}(\overline{W})},
$$

so that $\| R_h \|_{op} < \frac{1}{2C_0K}$. Therefore, $\Phi'(f)$ is a small perturbation of a surjective linear map, and standard methods based on iteration shows that it is surjective as a map from $C^{k,\theta}(\overline{W})$ to $C^{0}(\overline{W})$, and the equation $\Phi'(f)h = g$ can be solved with $\|h\|_{C^{k,\theta}(\overline{W})} < \frac{1}{2C_0K} \|g\|_{C^{0}(\overline{W})}$.

Since $\Phi'(f)$ is surjective, and $\Phi$ is $C^1$, we see that there is a small ball around $f$ which is mapped surjectively by $\Phi$ onto a ball around $\Phi(f)$. Therefore, given $\varepsilon > 0$ there is a $\delta > 0$ such that such that if $g$ in $C^{k-1,\theta}(\overline{W})$ is such that $\|g\|_{C^{k-1,\theta}(\overline{W})} < \delta$, then we can solve the equation

$$
\Phi(f + r) = \Phi(f) + g
$$

for an $r \in C^{k,\theta}(\overline{W})$ such that $\|r\|_{C^{k,\theta}(\overline{W})} < \varepsilon$.

Now we fix $\varepsilon = \varepsilon_0$ (where $\varepsilon_0$ is as in the beginning of this proof) and denote by $\delta_0$ the corresponding $\delta$. Let $C$ be a uniform bound for linear extension operators from $C^{k-1,\theta}(\overline{V})$ to $C^{k-1,\theta}(\overline{V})$ for any open subset $V$ of $\mathbb{C}$ (see Lemma 2.1) and let $\delta_1 = \frac{\delta_0}{C}$. Since by hypothesis $f \in C^{1,\beta}$, it follows that $\Phi(f) \in C^{\beta}$. We now use the hypothesis that $\beta > \theta$. Since $\Phi$ vanishes on $\Omega$, in a small enough neighborhood of $\overline{\Omega}$, we have that $\|\Phi(f)\|$ is small in the $C^{k-1,\theta}$ sense. Let $\Omega_0$ be a neighborhood of $\overline{\Omega}$ such that we have $\|\Phi(f)\|_{C^{k-1,\theta}(\Omega_0)} < \delta_1$. Denote by $g$ the map $-\Phi(f)|_{\Omega_0}$. Using a linear extension operator, we extend $g$ to a function $\tilde{g}$ in $C^{k-1,\theta}(\overline{W})$, such that $\|\tilde{g}\|_{C^{k-1,\theta}(\overline{W})} \leq C\delta_1 = \delta_0$. Therefore, the equation $\Phi(f + r) = \Phi(f) + \tilde{g}$ can be solved with for an $r$ such that $\|r\|_{C^{k,\theta}(\overline{W})} < \varepsilon_0$. Now, if we set $u = f + r$, we have that on
Ω, we have \( \Phi(u) = -g + g = 0 \), i.e., \( u \) is \( J \)-holomorphic. Of course, we have

\[
\| u - f \|_{C^k,\theta(\overline{\Omega})} \leq \| u - f \|_{C^k,\theta(\overline{W})} \\
\leq \| r \|_{C^k,\theta(\overline{W})} < \epsilon_0.
\]

\( \square \)

2.1. The general case. Now let \((X,J)\) be an almost complex manifold, with \( J \) of class \( C^{k,\theta} \), with \( k \geq 1 \). Let \( f \in A_{j}^{k+1,\theta}(\overline{\Omega},X) \). To prove Theorem \( \square \) we need to approximate \( f \) in the \( C^{k,\theta} \) topology on \( \overline{\Omega} \) by \( J \)-holomorphic maps.

We begin by making two observations. First, that it is no loss of generality to assume that \( f \) is an embedding. This is because we can replace \( X \) by \( X/BBV \times X \) and replace \( f \) by the map \( F : z \mapsto (z,f(z)) \), and obtain an approximation to \( F \), which we can subsequently project onto \( X \). We will therefore assume to begin with that \( f \) is an embedding.

The next observation is that we can extend \( f \) as a \( C^{k+1,\theta} \) map to all of \( BBV \). Therefore we will assume that \( f \) is defined and is an embedding on some large set \( U \) compactly, and \( f \) is \( J \)-holomorphic on \( \Omega \).

Let \( n \) denote the complex dimension of the \( a.c. \) manifold \( X \). It is easy to find \((n-1)\) smooth vector fields \( Y_2, Y_3, \ldots, Y_n \) on the embedded disc \( f(U) \) such that for any point \( z \) the \( \mathbb{C} \)-span of the vectors \( \frac{\partial f}{\partial z}(z), Y_2(f(z)), \ldots, Y_n(f(z)) \) in the space \( T_{f(z)}X \) with respect to the complex structure induced by \( J(f(z)) \) is the whole of \( T_{f(z)}X \). Now consider the map from \( U \times \mathbb{C}^{n-1} \subset \mathbb{C}^n \) into \( X \) given by

\[
(z_1, \ldots, z_n) \mapsto \exp \sum_{j=2}^{n} z_j Y_j(f(z_1))(f(z_1)).
\]

There is a neighborhood of \( U \times \mathbb{C}^{n-1} \) in \( \mathbb{C}^n \) which is mapped by the map in equation \( \square \) diffeomorphically onto \( \mathbb{C} \) of \( f(U) \) in \( X \). Therefore the inverse \( \varphi \) of the map in equation \( \square \) is a system of coordinates on \( U \). We note some properties of this coordinate map:

- \( \varphi \) is of class \( C^{k+1,\theta} \). Consequently, the smoothness of \( J \) is preserved, i.e., the induced structure \( J^\sharp \) on \( \mathbb{R}^{2n} \) is still \( C^{k,\theta} \).
- The map \( f \) is represented in these coordinates by

\[
\zeta \mapsto (\zeta, 0, \ldots, 0) \in \mathbb{C}^n.
\]
• On the set \( \overline{\Omega} \times \{0^{n-1}\} \) we have that \( J^\sharp = J_{st} \), the standard almost complex structure of \( \mathbb{C}^n \).

The problem is therefore reduced to that considered in the first section, and the approximation asserted in the theorem can be done.

3. Arcs in Complex Manifolds

We will denote by \( \mathcal{M} \) a complex manifold of complex dimension \( n \) on which we impose a Riemannian metric \( g \). The actual choice of the metric does not affect any of our results.

An arc is an injective continuous map from the interval \([0,1]\). We say that a \( C^1 \) arc \( \alpha \) is embedded if \( \alpha'(t) \neq 0 \) for each \( t \). For convenience of exposition we introduce the following terminology:

**Definition 3.1.** Let \( \alpha \) be an arc in \( \mathcal{M} \). Let \( \phi \) be a holomorphic submersion from a neighborhood of \( \alpha([0,1]) \) in \( \mathcal{M} \) into \( \mathbb{C} \). We will say that \( \phi \) is a **good submersion** for the arc \( \alpha \) if \( \phi \circ \alpha \) is a \( C^1 \) embedded arc in \( \mathbb{C} \).

Clearly, a smooth (at least \( C^1 \)) arc which admits a good submersion is embedded. Observe however that the definition does not require the arc to be smooth. Indeed, the existence of good submersions will serve as a convenient substitute for being embedded when we consider non-smooth arcs.

First we generalize Royden’s result on the existence of co-ordinate neighborhoods of real analytic arcs to smooth arcs. The proof of this result is based on a quantitative approximation of \( C^k \) arcs by real analytic arcs (see Lemma \[3.5\] below.)

Our first result is as follows:

**Proposition 3.2.** Let \( k \geq 2 \) and let \( \alpha \) be an embedded \( C^k \) arc in \( \mathcal{M} \). Then there is a family \( \{\phi_j\}_{j=1}^n \) of \( n \) good submersions associated with \( \alpha \), such that they form a coordinate system in a neighborhood of the image of \( \alpha \).

In particular, smooth arcs of class at least \( C^2 \) have coordinate neighborhoods. Also, a \( C^2 \) arc is embedded iff it has a good submersion.

We next consider \( C^1 \) arcs in \( \mathcal{M} \). Unfortunately, in this case, the approximation lemma \[3.5\] is not strong enough to prove the existence of coordinate neighborhoods.
if we simply assume that $\alpha$ is embedded. However, we can prove the following:

\textbf{Proposition 3.3.} Let $\alpha$ be a $C^1$ arc in $\mathcal{M}$ which admits a good submersion $\phi$. There is a coordinate neighborhood $W$ of $\alpha([0,1])$ in $\mathcal{M}$ and a biholomorphic map $(\phi_1, \ldots, \phi_n)$ from $W$ onto an open subset of $\mathbb{C}^n$ such that $\phi_n = \phi|_W$.

In other words, given a good submersion in a neighborhood of the image of an arc in $\mathcal{M}$, we can find $n-1$ other functions such that the $n$ functions together form a system of coordinates in a neighborhood of $\alpha$. Observe that, for $j = 1, \ldots, n-1$, after replacing the function $\phi_j$ by the function $\phi_j + K\phi$, for large enough $K$, we may assume that each of the coordinate functions $\phi_j$ is a good submersion, thus strengthening the conclusion.

We now turn to non-smooth arcs. In view of the intended application in the next section we introduce the following definition:

\textbf{Definition 3.4.} Let $k \geq 1$. Suppose $\alpha : [0,1] \to \mathcal{M}$ is an arc such that

- $\alpha$ is $C^k$ outside a finite subset $P \subset [0,1]$, and
- $\alpha$ admits a good submersion $\phi$.

We will refer to such arcs $\alpha$ as $C^k$ arcs with mild singularities or mildly singular arcs.

Our result concerning mildly singular arcs is as follows:

\textbf{Theorem 2.} Let $\alpha$ be a $C^3$ arc in $\mathcal{M}$ with mild singularities, and let $\phi$ be the associated good submersion. Then the image $\alpha([0,1])$ has a coordinate neighborhood $W$ and a coordinate map $(\phi_1, \ldots, \phi_n) : W \to \mathbb{C}^n$, with $\phi_n = \phi|_W$.

3.1. \textbf{Approximation of smooth functions by real-analytic functions.} The following approximation lemma is required in the proof of the fact that smooth arcs have coordinate neighborhoods.

\textbf{Lemma 3.5.} Let $\Gamma$ denote either the image of the unit interval $[0,1]$ or of the unit circle $S^1$ under a $C^k$ embedding into $\mathbb{C}$, where $k \geq 1$. Let $f$ be a $C^k$ function defined on $\Gamma$, and $\theta$ be such that $0 < \theta < 1$. Then there is a constant $C > 0$ and a $C^k$ extension of $f$ to a neighborhood of $\Gamma$ such that for small enough $\delta > 0$ there is a holomorphic map $f_\delta$ defined in the closed $\delta$ neighborhood $\overline{B}_{\mathbb{C}}(\Gamma, \delta)$ of $\Gamma$ such that
if $\alpha$ and $\beta$ be nonnegative integers such that $\alpha + \beta < k$, then for $z \in B_{\mathbb{C}}(\Gamma, \delta)$ we have

$$\left| \left( \frac{\partial^{\alpha+\beta}}{\partial z^\alpha \partial \overline{z}^\beta} \right) (f(z) - f_{\delta}(z)) \right| < C \delta^{k-\frac{1}{2}-(\alpha+\beta)}.$$

Further,

- $f_{\delta}$ is bounded independently of $\delta$ in the $C^{k-1,\theta}$ norm, or more precisely, we have $\| f_{\delta} \|_{C^{k-1,\theta}(B_{\mathbb{C}}(\Gamma, \delta))} < C$.

Proof. We will denote by $C$ any constant which is independent of $\delta$.

For small $\delta > 0$, let $\chi_{\delta}$ be a $C^\infty_c$ cutoff on $\mathbb{C}$ such that $\chi_{\delta} \equiv 1$ in a neighborhood of $B_{\mathbb{C}}(\Gamma, \delta)$ and vanishes off the $2\delta$-neighborhood $B_{\mathbb{C}}(\Gamma, 2\delta)$. We may choose the $\chi_{\delta}$ that there is a constant $C$ (which of course depends on $k$) such that for small $\delta$ and every pair of non-negative integers $\alpha$ and $\beta$ such that $\alpha + \beta < k$ we have:

$$\left| \left( \frac{\partial^{\alpha+\beta}}{\partial z^\alpha \partial \overline{z}^\beta} \right) \chi_{\delta}(z) \right| < \frac{C}{\delta^{\alpha+\beta}}.$$

Since $\Gamma$ is totally real, using the Whitney Extension Theorem, we can extend $f$ as a $C^k$ function on $\mathbb{C}$ such that the $\overline{\partial}$-derivative $\frac{\partial f}{\partial \overline{z}}$ vanishes to order $k-1$ on $\Gamma$. Continuing to denote the extended function by $f$ and denoting by $\eta(z)$ the distance from $z \in \mathbb{C}$ to the set $\Gamma$, we see that

$$\left| \left( \frac{\partial^{\alpha+\beta}}{\partial z^\alpha \partial \overline{z}^\beta} \right) \left( \frac{\partial f}{\partial \overline{z}} \right)(z) \right| < C \eta(z)^{k-1-(\alpha+\beta)}.$$ 

Now we define (suppressing the dependence on $\delta$ in the notation):

$$\lambda_{(\alpha,\beta)}(z) = \frac{\partial^{\alpha+\beta}}{\partial z^\alpha \partial \overline{z}^\beta} \left( \chi_{\delta} \cdot \frac{\partial f}{\partial \overline{z}} \right)(z).$$

Observe that $\lambda_{(\alpha,\beta)}$ is supported in $B_{\mathbb{C}}(\Gamma, 2\delta)$ for every $\delta$ and we have $|\lambda_{(\alpha,\beta)}| = O(\delta^{k-1-(\alpha+\beta)})$.

Let the function $u_{\delta}$ on $\mathbb{C}$ be defined by:

$$u_{\delta}(z) := \frac{-1}{\pi z} \ast \lambda_{(0,0)}(z) = \frac{-1}{\pi z} \ast \left( \chi_{\delta}(z) \cdot \frac{\partial f}{\partial \overline{z}}(z) \right).$$
Then \( f_\delta = f + u_\delta \) is clearly holomorphic on \( \overline{B_C(\Gamma, \delta)} \), and we have
\[
\frac{\partial^{\alpha+\beta}}{\partial z^\alpha \partial \overline{\zeta}^\beta} u_\delta (z) = \frac{-1}{\pi z} \int \int_{B_C(\Gamma, 2\delta)} \frac{1}{\zeta - z} \cdot \lambda(\alpha, \beta)(\zeta) d\xi d\eta (\zeta = \xi + i\eta) 
\]
\[
= \frac{-1}{\pi} \left( \int \int_{B_C(\Gamma, 2\delta) \cap \{\zeta : |\zeta - z| < \sqrt{\delta} \}} + \int \int_{B_C(\Gamma, 2\delta) \cap \{\zeta : |\zeta - z| \geq \sqrt{\delta} \}} \right) 
\]
\[
= -\frac{1}{\pi} (I_1 + I_2) .
\]
We can now estimate:
\[
|I_1| \leq \frac{1}{\pi} \|\lambda(\alpha, \beta)\|_L^\infty \int \int_{\{\zeta : |\zeta - z| < \sqrt{\delta} \}} \frac{1}{|z - \zeta|} d\xi d\eta 
\]
\[
\leq \frac{1}{\pi} \cdot C \delta^{k-1-(\alpha+\beta)} \cdot 2\pi \sqrt{\delta} 
\]
\[
\leq C \delta^{k-\frac{1}{2}-(\alpha+\beta)}
\]
and
\[
|I_2| \leq \frac{1}{\pi} \|\lambda(\alpha, \beta)\|_L^\infty \int \int_{B_C(\Gamma, 2\delta) \cap \{\zeta : |\zeta - z| \geq \sqrt{\delta} \}} \frac{1}{|z - \zeta|} d\xi d\eta 
\]
\[
\leq \frac{1}{\pi} \cdot C \delta^{k-1-(\alpha+\beta)} \cdot \frac{1}{\sqrt{\delta}} \cdot \text{Area} (B_C(\Gamma, 2\delta)) 
\]
\[
\leq C \delta^{k-1-(\alpha+\beta)} \cdot \frac{1}{\sqrt{\delta}} C \delta 
\]
\[
\leq C \delta^{k-\frac{1}{2}-(\alpha+\beta)}
\]
which proves the first conclusion of the lemma. Moreover, it immediately follows that for \( f_\delta = f + u_\delta \) we have that \( \|f_\delta\|_{C^{k-1}} < C \) for some \( C \) independent of \( \delta \). To complete the proof, it is sufficient to recall the well known fact that for functions \( v \) on \( C \) supported in a fixed compact set \( E \), the assignment \( v \mapsto \frac{1}{z} * v \) is continuous from \( C(E) \) to \( C^{0,\theta}(E) \). \( \square \)

3.2. \( C^k \) embedded arcs, \( k \geq 2 \). This section is devoted to the proof of Proposition 3.2. We will need the following two lemmas:

Lemma 3.6. For convenience, let \( B = B_{R^N}(0,1) \), the \( N \)-dimensional unit ball. Let \( \Phi : \overline{B} \to \mathbb{R}^N \) be a \( C^1 \) map such that for some constant \( C > 0 \),
for each tangent vector $v$, we have $\|\Phi'(0)v\| \geq C \|v\|$, and

for each $x \in \overline{B}$, we have $\|\Phi'(x) - \Phi'(0)\|_{op} < \frac{C}{2}$.

Then, $\Phi(B) \supset B_{\mathbb{R}^N}(\Phi(0), \frac{C}{2})$.

**Proof.** After a translation and dilation, we can assume that $\Phi(0) = 0$ and $C = 2$. Fix $x \in \overline{B}$ and let $u(t) = \Phi(tx)$. We have:

$$
\|\Phi(x)\| = \left\| \int_0^1 u'(t)dt \right\| = \left\| \int_0^1 \Phi'(tx) x dt \right\|
= \left\| \int_0^1 \Phi'(0)x dt + \int_0^1 (\Phi'(tx) - \Phi'(0)) dt \right\|
\geq \|\Phi'(0)x\| - \left\| \int_0^1 (\Phi'(tx) - \Phi'(0)) x dt \right\|
\geq 2 \|x\| - \|x\| \geq \|x\|.
$$

Let $\Sigma = B \cap \Phi(B)$. Then $\Sigma$ is nonempty ($0 \in \Sigma$) and closed in the relative topology of $B$. Now as $\Phi$ is expanding, $B \cap \Phi(B) = B \cap \Phi(B)$. Since $\Phi$ is a local diffeomorphism, it follows from this that $\Sigma$ is open in $B$ as well, which implies by connectedness that $\Sigma = B$, that is, $B \subset \Phi(B)$, which is the required conclusion. \hfill \Box

**Lemma 3.7.** Let $S$ be a sufficiently smooth compact totally real submanifold of $M$. Then, there is an $\eta > 0$ such that the $\eta$ neighborhood $B_M(S, \eta)$ of $S$ is a Stein open subset of $M$ and any continuous function on $S$ can be uniformly approximated by the restrictions to $S$ of functions holomorphic on this $\eta$ neighborhood.

“Sufficiently smooth” in this context means $C^s$, where $s$ is an integer which is at least 2 and greater than $\frac{1}{2} \dim_{\mathbb{R}} S + 1$.

In the case when $S$ is $C^\infty$, this result is due to Nirenberg and Wells (see [3], Theorem 6.1 and Corollary 6.2.) Since the submanifold $S$ is of class at least $C^2$, the square of the distance to $S$ is strictly plurisubharmonic in a neighborhood, from which it follows that $B_M(S, \eta)$ is Stein. After embedding it in some $\mathbb{C}^N$ and using a retraction onto the embedded submanifold, this reduces to [11] Theorem 17.1. (It is known that the smoothness assumed in this result is not the best possible.) In our application, we will only be require the case in which $S$ is diffeomorphic to the circle.
Now we turn to the proof of Proposition 3.2. We will in fact prove the following proposition:

**Proposition 3.8.** Let $k \geq 2$ and let $\alpha : S^1 \to M$ be a $C^k$ embedding of the circle. Then the image $\alpha(S^1)$ has a coordinate neighborhood $W$ in $M$ such that there is a coordinate map $(\phi_1, \ldots, \phi_n) : W \to \mathbb{C}^n$ with each $\phi_j \circ \alpha$ a $C^k$ embedding of $S^1$ into $\mathbb{C}$.

Indeed, any embedding of the interval can be extended to an embedding of the circle, so Proposition 3.8 immediately implies Proposition 3.2.

**Proof.** It is sufficient to consider the case of $k = 2$. Denote by $A_\delta$ the $\delta$ neighborhood $B_{C^n}(S^1 \times 0_{C^n-1})$ of the circle $S^1 \times 0_{C^n-1}$ in $\mathbb{C}^n$. For small $\delta > 0$ we will construct a biholomorphic map $\Phi_\delta$ from $A_\delta$ onto an open subset of $M$ such that the image of $\Phi_\delta$ will contain the embedded circle $\alpha(S^1)$. Consequently $\Phi_\delta^{-1}$ is a coordinate map in a neighborhood of $\alpha(S^1)$.

For $\eta > 0$, let $X_\eta = B_M(\alpha(S^1), \eta)$. Also, for a vector field $V$ on a manifold and a point $p$ on the manifold let $\exp_V p$ be the point to which $p$ flows in unit time along the field $V$, that is $X(1)$, where $X(0) = p$ and $X'(t) = V(X(t))$. The map $\exp_V p$ depends holomorphically on the vector field $V$ and the point $p$.

We define a map from $A_\delta \subset \mathbb{C}^n$ to $X_\eta \subset M$ by setting:

$$\Phi_\delta(z_1, \ldots, z_n) = \exp_{\sum_{j=2}^n z_j f_j} \alpha_\delta(z_1),$$

where the number $\eta > 0$, the vector fields $\{f_j\}_{j=2}^n$ on the open submanifold $X_\eta$, and the map $\alpha_\delta : B_{C^2}(S^1, \delta) \to X_\eta$ are as follows:

1. The holomorphic vector fields $\{f_j\}_{j=2}^n$, are such that for each $z \in S^1 \subset \mathbb{C}$, the set of vectors $\{\alpha'(z), f_2(\alpha(z)), \ldots, f_n(\alpha(z))\}$ spans the tangent space $T_{\alpha(z)}M$ over $\mathbb{C}$.

To see that such $f_j$ exist, we note that $X_\eta$ is diffeomorphic to an open solid torus in $\mathbb{C}^n$, and is Stein for small $\eta$. Therefore by an application of the Oka principle, the tangent bundle $TX_\eta$ is trivial. Also, thanks to Lemma 3.7 any continuous function on the one dimensional totally real submanifold $\alpha(S^1)$ may be approximated by holomorphic functions in some neighborhood. Therefore, the existence of the $f_j$ follows on approximating smooth vector fields $\{g_j\}_{j=2}^n$ on $\alpha(S^1)$ such that the set $\{\alpha'(z), g_2(\alpha(z)), \ldots, g_n(\alpha(z))\}$ spans $T_{\alpha(z)}M$, and shrinking $\eta$ to ensure the holomorphic approximants $f_j$ are defined on $X_\eta$.
(2) Now we specify the map \( \alpha_\delta \). This will be a holomorphic map defined on \( B_{\mathbb{C}}(S^1, \delta) \) and taking values in \( \mathcal{X}_\eta \subset \mathcal{M} \) such that for some \( 0 < \theta < 1 \):

- on \( S^1 \) we have \( \text{dist}(\alpha_\delta, \alpha) < C\delta^{\frac{3}{2}} \), as well as \( \text{dist}(\nabla \alpha_\delta, \nabla \alpha) < C\delta^{\frac{3}{2}} \).
- there is a constant \( C \) (independent of \( \delta \)) such that and on \( B_{\mathbb{C}}(S^1, \delta) \) we have \( \|\alpha_\delta\|_{C^{1,\theta}} < C \).

To construct \( \alpha_\delta \) we note that since \( \mathcal{X}_\eta \) is Stein, there is an embedding \( j : \mathcal{X}_\eta \to \mathbb{C}^M \) for large \( M \), and there is a holomorphic retraction of a neighborhood of \( j(\mathcal{X}_\eta) \) onto \( \mathcal{X}_\eta \). Fix \( \theta \), where \( 0 < \theta < 1 \). Since \( \alpha \) is of class \( C^2 \), we can use Lemma 3.5 above to find a holomorphic approximation \( \alpha_\delta \) defined in a \( \delta \) neighborhood of the circle \( B_{\mathbb{C}}(S^1, \delta) \) of \( S^1 \) in \( \mathbb{C} \), and taking values in \( \mathcal{X}_\eta \) such that the two conditions above are satisfied.

For small \( \delta \), the set \( \{\alpha_\delta'(z), f_2(\alpha_\delta(z)), \ldots, f_n(\alpha_\delta(z))\} \) spans \( T_{\alpha_\delta(z)} \mathcal{M} \) for \( z \in B_{\mathbb{C}}(S^1, \delta) \). Moreover, for small \( \delta \), the map \( \alpha_\delta \) is an embedding. Therefore, for small enough \( \delta \) the map \( \Phi_\delta \) is well defined and is a biholomorphism from \( A_\delta \) into \( \mathcal{X}_\eta \). Since the \( C^{1,\theta} \) norm of \( \alpha_\delta \) on \( B_{\mathbb{C}}(S^1, \delta) \) is bounded independently of \( \delta \), we conclude that \( \Phi_\delta \) must be bounded in the \( C^{1,\theta} \) norm on \( A_\delta \). Recall that the tangent bundle of \( T\mathcal{X}_\eta \) is holomorphically trivial, and fix a trivialization. Then \( \Phi_\delta' : A_\delta \to \text{Mat}_{n \times n}(\mathbb{C}) \) is a \( C^\theta \) map. Therefore for a constant \( C_1 \) independent of \( \delta \) and any \( Z \) and \( W \) in \( A_\delta \) we have \( \|\Phi_\delta'(W) - \Phi_\delta'(Z)\|_{\text{op}} \leq C_1 \|W - Z\|^\theta \).

In particular, if \( Z \) lies on the circle \( S^1 \times 0_{\mathbb{C}^{n-1}} \), and \( W \) is in the ball \( B_{g^n}(Z, \delta) \subset A_\delta \), then we will have

\[
\|\Phi_\delta'(W) - \Phi_\delta'(Z)\|_{\text{op}} \leq C_1 \delta^\theta. \tag{6}
\]

We claim that there is a constant \( C_2 \) independent of \( \delta \) such that if \( \delta > 0 \) is small, for every \( Z \in A_\delta \) and every tangent vector \( v \) we have

\[
\|\Phi_\delta'(Z)v\| \geq C_2 \|v\|. \tag{7}
\]

To see this, let \( \tilde{\alpha} \) be an extension of \( \alpha \) to a neighborhood of \( S^1 \) in \( \mathbb{C} \) such that we have \( \|\nabla \tilde{\alpha} - \nabla \alpha_\delta\| = O(\delta^{\frac{3}{2}}) \) (see the first conclusion of Lemma 3.5). The map \( \tilde{\alpha} \) is \( C^2 \) and \( \overline{\partial} \tilde{\alpha} \) vanishes along \( \Gamma \). We define a map \( \tilde{\Phi} \) by setting:

\[
\tilde{\Phi}(z_1, \ldots, z_n) = \exp_{\sum_{j=1}^n z_j f_j} \tilde{\alpha}(z_1).
\]

Then \( \tilde{\Phi} \) is a diffeomorphism from a neighborhood \( A \) of \( S^1 \times 0_{\mathbb{C}^{n-1}} \) in \( \mathbb{C}^n \) into \( \mathcal{M} \), and satisfies \( \|\Phi_\delta' - \tilde{\Phi}'\| = O(\delta^{\frac{3}{2}}) \). Clearly, there is a constant \( C > 0 \) such that for
any \( Z \in A \) and tangent vector \( v \) we have \( \| \tilde{\Phi}'(Z)(v) \| \geq C \| v \| \). The existence of the constant \( C_2 \) of estimate \textcolor{red}{7} now follows immediately.

By an application of Lemma \textcolor{red}{3.6} above to the inequalities it follows that there is a \( \delta_0 > 0 \), and a constant \( K \) independent of \( \delta \) such that for \( \delta < \delta_0 \), and \( Z \in S^1 \times 0_{\mathbb{C}^{n-1}} \) we have \( \Phi_\delta(B_{\mathbb{C}^n}(Z,\delta)) \supset B_M(\Phi_\delta(Z),K\delta) \). Since for a point of the form \( Z = (z,0,\ldots) \in S^1 \times 0_{\mathbb{C}^{n-1}} \), we have \( \Phi_\delta(Z) = \alpha_\delta(z) \), we see that \( \Phi_\delta(A_\delta) \supset B_M(\alpha_\delta(S^1),K\delta) \). On the other hand, for \( z \in S^1 \),

\[
\text{dist}_M(\alpha(z),\Phi_\delta(z,0,\ldots,0)) \leq \text{dist}_M(\alpha(z),\alpha_\delta(z)) = O(\delta^3).
\]

Therefore for small \( \delta \) we have, \( \alpha(S^1) \subset \Phi_\delta(A_\delta) \), which shows that \( \Phi_\delta^{-1} : \Phi_\delta(A_\delta) \to \mathbb{C}^n \) is a coordinate map (biholomorphism onto an open subset of \( \mathbb{C}^n \)) defined in the neighborhood \( \Phi_\delta(A_\delta) \) of \( \alpha(S^1) \) in \( \mathcal{M} \).

Note that as \( \delta \to 0 \), the maps \( \Phi_\delta^{-1} \circ \alpha_\delta \to j \) on \( S^1 \) in the \( C^1 \) sense, where \( j \) denotes the embedding of \( S^1 \) in \( \mathbb{C}^n \) as \( S^1 \times 0^{n-1} \). Since \( \alpha_\delta \to \alpha \) in \( C^1 \), it follows that for small \( \delta \), the first coordinate of \( \Phi_\delta^{-1} \circ \alpha \) is an embedding of \( [0,1] \) into \( \mathbb{C} \). Writing \( \Phi_\delta^{-1} \) in coordinates as \( (\phi_1,\ldots,\phi_n) \), therefore, \( \phi_1 \circ \alpha \) is an embedded arc in \( \mathbb{C} \) (which is obviously of class \( C^2 \)). We now consider the coordinate system \( (\phi_1,\phi_2 + K\phi_1,\ldots,\phi_n + K\phi_1) \) in which for \( j > 1 \), \( \phi_j \) is replaced by \( \phi_j + K\phi_1 \). For large \( K \), every coordinate of this map is a \( C^1 \) embedding when restricted on \( \alpha \). \( \square \)

### 3.3. Coordinate neighborhoods of \( C^1 \) arcs.

We now prove Proposition \textcolor{red}{3.3}. The first step is to show that the image \( \alpha([0,1]) \) has a \textit{Stein} neighborhood. We begin with the following elementary observations:

**Observation 3.9.** Let \( \gamma : [0,1] \to \mathcal{M} \) be an arc. Then \( \gamma([0,1]) \) has a neighborhood \( W \) such that there is a strictly plurisubharmonic function \( \rho \) defined on \( W \).

Note that no regularity assumption apart from injectivity has been made on \( \gamma \).

**Proof.** There is of course a strictly plurisubharmonic function in a neighborhood of \( \gamma(0) \). Suppose that for some \( 0 < p < q < 1 \) the segment \( \gamma([p,q]) \) is in a coordinate chart of \( \mathcal{M} \), and \( \rho \) is a strictly plurisubharmonic function in a neighborhood of \( \gamma([0,p]) \). By an induction on a cover of \( \gamma([0,1]) \) by coordinate charts, it is sufficient to construct a strictly plurisubharmonic function in a neighborhood of \( \gamma([0,q]) \). After subtracting a constant, \( \rho(\gamma(p)) = 0 \), and there is a coordinate map \( Z \) on a
neighborhood of $\gamma([p,q])$ so that $Z(p) = 0 \in \mathbb{C}^n$. Fix an $r$ with $p < r < q$ so that $\rho$ is defined on $[p,r]$. Now we can define the function $\tilde{\rho}$ as follows:

$$
\tilde{\rho} = \begin{cases} 
\rho & \text{near } \gamma([0,p]) \\
\max(\rho, K\|Z\|^2 - 1) & \text{near } \gamma([p,r]) \text{ with } K \text{ large (see below)} \\
K\|Z\|^2 - 1 & \text{near } \gamma([r,q])
\end{cases}
$$

We take $K$ in the above expression so large that $K\|Z(\gamma(r))\|^2 - 1 > \rho(\gamma(r))$. Then $\tilde{\rho}$ is $\rho$ near $\gamma([0,p])$ and $K\|Z\|^2 - 1$ near the other endpoint $\gamma(r)$ of $\gamma([p,r])$ and continues to the next chart. $\square$

The following is a well known general fact regarding polynomially convex sets:

**Observation 3.10.** Let $X$ be a compact polynomially convex subset of $\mathbb{C}^N$, an $\lambda \geq 0$ be a continuous function on $\mathbb{C}^N$ such that $\lambda = 0$ exactly on $X$. Then, given any neighborhood $W$ of $X$, there is a continuous plurisubharmonic function $\rho \geq 0$ such that $\rho = 0$ exactly on $X$, and on $W$, we have $\rho < \lambda$.

**Proof.** For each $p \in \mathbb{C}^n \setminus X$ there exists a continuous plurisubharmonic function $\rho_p \geq 0$ defined on $\mathbb{C}^n$ such that $\rho_p(p) > 0$, and $\rho$ vanishes in a neighborhood of $X$. There exists a sequence $x_j$ in $\mathbb{C}^n \setminus X$ such that for all $z \in \mathbb{C}^n \setminus X$ there exists an integer $j$ such that $\rho_{x_j}(z) > 0$. Set $\rho = \sum \epsilon_j \rho_{x_j}$, with $\epsilon_j > 0$ small enough to ensure that $\epsilon_j \rho_{x_j} \leq 2^{-j}\lambda$ on $W \cup B_{\mathbb{C}^n}(0,j)$. $\square$

We will now prove the following lemma:

**Lemma 3.11.** Let $\gamma : [0,1] \to M$ be a $C^1$ embedded arc in a complex manifold $M$. Then there is a $\delta > 0$ with the following properties:

(a) Let $0 \leq t_0 < t_1 \leq 1$ be such that $|t_0 - t_1| < \delta$, and let $W_0$ and $W_1$ be given neighborhoods of $\gamma(t_0)$ and $\gamma(t_1)$ in $M$. Then there is a plurisubharmonic function $\rho \geq 0$ defined in a neighborhood of $\gamma([t_0,t_1])$ in $M$ such that $\rho^{-1}(0) = V_0 \cup \gamma([t_0,t_1]) \cup V_1$, where $V_j \subset W_j$ are compact neighborhoods of $\gamma(t_j)$ (for $j = 0, 1$).

(b) Let $t_1$ be such that $0 < t_1< \delta$ (resp. $0 < 1 - t_1 < \delta$), and $W_1$ be a neighborhood of $\gamma(t_1)$ in $M$. Then there is a plurisubharmonic function $\rho \geq 0$ defined in a neighborhood of $\gamma([0,t_1])$ (resp. $\gamma([t_1,1])$) such that $\rho^{-1}(0) = V_1 \cup \gamma([0,t_1])$ (resp. $\rho^{-1}(0) = \gamma([t_1,1]) \cup V_1$).
Proof. Using compactness and local coordinates, it is clear that is suffices to prove
the result for $\mathcal{M} = \mathbb{C}^n$. We only prove statement (a) above, since the proof of (b)
involves only minor changes.

Let $t_0 \in [0, 1]$. After a linear change of coordinates, we can assume that for each
$j = 1, \ldots, n$, the components of the tangent vector $\gamma_j'(t_0)$ are non-zero. We let $\delta_{t_0}$
so small that on $[t_0 - \delta_{t_0}, t_0 + \delta_{t_0}]$ the component functions $\gamma_j$ are $C^1$ embeddings
into $\mathbb{C}$.

Now suppose we are given neighborhoods $W_0$ and $W_1$ of $\gamma(t_0)$ and $\gamma(t_1)$ in $\mathcal{M}$.
Choose $r > 0$ so small that for $j = 1, \ldots, n$ the closed discs $\overline{B_\mathbb{C}(\gamma_j(t_0), r)}$ and
$\overline{B_\mathbb{C}(\gamma_j(t_1), r)}$ are contained in the sets $\pi_j(W_0)$ and $\pi_j(W_1)$ respectively, where $\pi_j : \mathbb{C}^n \to \mathbb{C}$ is the $j$-th coordinate function. For small $r$, the subset of $\mathbb{C}$

$$K_j = B_\mathbb{C}(\gamma_j(t_0), r) \cup \gamma_j([t_0, t_1]) \cup B_\mathbb{C}(\gamma_j(t_1), r)$$

is polynomially convex, and therefore there is a plurisubharmonic $\rho_j \geq 0$ on $\mathbb{C}$
which vanishes exactly on $K_j$. Let $\rho := \sum_{j=1}^n \rho_j \circ \pi_j$. Then clearly $\rho^{-1}(0)$ is the
union of the subarc $\gamma([t_0, t_1])$ with two closed polydiscs of polyradius $r$ centered
at the endpoints $\gamma(t_0)$ and $\gamma(t_1)$, which are contained in $W_0$ and $W_1$ respectively.
Choosing $\delta$ uniformly for all $t_0$ by compactness, conclusion (a) follows. \hfill $\Box$

We can now prove Proposition 3.3.

It is clear that $\alpha$ is an embedded arc. We consider two partitions of the interval
$[0, 1]$

$$0 < t_1 < \cdots < t_{N-1} < 1,$$

and

$$0 < t'_1 < \cdots < t'_{N-1} < 1,$$

such that for each $j$ we have $t_j \neq t'_j$. We set $t_0 = t'_0 = 0$ and $t_N = t'_N = 1$. We
will choose the partitions in such a way that $|t_j - t_{j+1}| < \delta$ and $|t'_j - t'_{j+1}| < \delta$ for
$j = 0, 1, \ldots, N - 1$, where $\delta$ is as in the conclusion of Lemma 3.11 above. Suppose
that for $j = 1, \ldots, N - 1$, the open neighborhoods $W_j$ and $W'_j$ of $\gamma(t_j)$ and $\gamma(t_{j+1})$
are such that $W_j \cap W'_j = \emptyset$.

We now apply lemma 3.11. For $j = 1, \ldots, N - 1$, let $\rho_j$ be a nonnegative plurisubharmonic function in a neighborhood of $\alpha([t_j, t_{j+1}])$ which vanishes exactly
on $\alpha([t_j, t_{j+1}]) \cup V_j \cup V'_{j+1}$, where $V_j \subset W_j$ and $V'_{j+1} \subset W_{j+1}$ contain the points $\alpha(t_j)$
and $\alpha(t_{j+1})$ respectively. Let $\rho_0$ and $\rho_N$ be non-negative and plurisubharmonic on
neighborhoods of \( \alpha([0, t_1]) \) and \( \alpha([t_N, 1]) \) respectively such that \( \rho_0^{-1}(0) = \alpha([0, t_1]) \cup V_1 \) and \( \rho_N^{-1}(0) = \alpha([t_{N-1}, 1]) \cup V_{N-1} \), where \( \alpha(t_1) \in V_1 \subset W_1 \) and \( \alpha(t_{N-1}) \in V_{N-1} \subset W_{N-1} \). There is a function \( \rho \geq 0 \) in a neighborhood of \( \alpha([0, 1]) \) which to be equal to \( \rho_j \) in a neighborhood of \( \alpha([t_j, t_{j+1}]) \). Since \( \rho \) is locally the max of plurisubharmonic functions, it is itself plurisubharmonic and vanishes exactly on the arc \( \alpha([0, 1]) \) and on small neighborhoods of \( \alpha(t_j) \) contained in \( W_j \) (where \( j = 1, \ldots, N-1 \)).

The same way we obtain a plurisubharmonic \( \rho' \geq 0 \) which vanishes exactly on the arc \( \alpha([0, 1]) \) and small neighborhoods of \( \alpha(t'_j) \) contained in \( W'_j \) (where \( j = 1, \ldots, N-1 \)). Then \( \tilde{\rho} = \rho + \rho' \) is a plurisubharmonic function in a neighborhood of \( \alpha([0, 1]) \) which vanishes exactly on \( \alpha([0, 1]) \). Let \( \epsilon > 0 \) be small, and \( \psi \) be a strictly plurisubharmonic function in a neighborhood of \( \alpha([0, 1]) \). Then the open set \( \Omega = \{ \tilde{\rho} < \epsilon \} \) supports the strictly plurisubharmonic exhaustion function \( (\epsilon - \tilde{\rho})^{-1} + \psi \), and is consequently Stein. If \( \epsilon \) is small, the submersion \( \phi \) is defined on \( \Omega \). There is an embedding \( j : \Omega \hookrightarrow \mathbb{C}^N \) for large enough \( N \). Let \( \tilde{j} : \Omega \hookrightarrow \mathbb{C}^{N+1} \) be the map \( \tilde{j}(z) := (j(z), \phi(z)) \), where \( \phi \) is the good submersion associated with the arc \( \alpha \), whose existence is assumed in the hypothesis. Then \( \tilde{j} \) is again an embedding. Let \( \mathcal{X} := \tilde{j}(\Omega) \). Then,

- \( \mathcal{X} \) is a complex submanifold of \( \mathbb{C}^{N+1} = \mathbb{C}^N \times \mathbb{C} \).
- \( z_{N+1} : \mathcal{X} \to \mathbb{C} \) is submersion.
- Let \( \tilde{\alpha} = \tilde{j} \circ \alpha \). Then \( \tilde{\alpha} \) is a \( C^1 \) embedded arc in \( \mathcal{X} \subset \mathbb{C}^{N+1} \), such that the last coordinate \( \alpha_{N+1} : [0, 1] \to \mathbb{C} \) is a \( C^1 \) embedding, and
- \( \phi \circ \alpha : [0, 1] \to \mathbb{C} \) is a \( C^1 \) embedding. Set \( \Gamma = \phi(\alpha([0, 1])) \) and let \( \psi : \Gamma \to [0, 1] \) be the inverse \( \psi = (\phi \circ \alpha)^{-1} \). We let

\[
\tilde{\beta}(z) := (\beta(z), z) \\
:= (j \circ \alpha \circ \psi(z), z)
\]

To prove our result, it is sufficient to show that \( \tilde{\beta}(\Gamma) \) has a neighborhood \( W \) in \( \mathcal{X} \) such that \( W \) is biholomorphic to an open subset of \( \mathbb{C}^n \) and there is a biholomorphism \( w = (w_1, \ldots, w_n) \) from \( W \) into \( \mathbb{C}^n \) such that \( w_n = z_{N+1}|_{\mathcal{X}} \) (where \( (z_1, \ldots, z_N) \) are the coordinates of \( \mathbb{C}^{N+1} \) in which \( \mathcal{X} \) is embedded).

We will construct the map \( w \) by first defining it on a neighborhood of \( \tilde{\beta}(\Gamma) \) in \( \mathbb{C}^{N+1} \) and its restriction to \( \tilde{X} \) will provide us with the required biholomorphic map.
To do this let \( \{ g_i \}_{i=1}^{n-1} \) be smooth maps from \( \Gamma \) into \( \mathbb{C}^N \) such that for each \( z \in \Gamma \) they, along with \( \beta'(z) \) span the tangent space \( T_{\beta(z)}(\mathcal{X}) \subset \mathbb{C}^N \). If the \( \mathbb{C}^{N+1} \) valued maps \( \{ f_i \}_{i=1}^{n-1} \) are formed from \( g_i \) by taking the last coordinate to be 0, then the \( f_i(z) \) along with the vector \( \tilde{\beta}'(z) = (\beta'(z), 1) \) span the tangent space \( T_{\tilde{\beta}(z)}(\mathcal{X}) \).

Let \( A \) be a \( \text{Mat}_{n \times N}(\mathbb{C}) \) valued smooth map on \( \Gamma \) such that \( A(z)g_i(z) = e_i \) for each \( i = 1, \ldots, n-1 \). We can approximate \( A \) uniformly on \( \Gamma \) by a holomorphic matrix valued map \( B \) defined in a neighborhood of \( \Gamma \) in \( \mathbb{C}^{N+1} \). Now we consider the map \( \Lambda \)

\[
\Lambda(z_1, \ldots, z_{N+1}) := \begin{pmatrix} B(z_{N+1}) & \left( \begin{array}{c} z_1 \\ \vdots \\ z_N \end{array} \right), z_{N+1} \end{pmatrix}
\]

which is defined in a neighborhood of the arc \( \tilde{\beta}(\Gamma) \) in \( \mathbb{C}^{N+1} \). Its derivative is given by the matrix

\[
\Lambda'(z_1, \ldots, z_{N+1}) = \begin{pmatrix} B(z_{N+1}), & B'(z_{N+1}) & \left( \begin{array}{c} z_1 \\ \vdots \\ z_N \end{array} \right) \\ 0, & 1 \end{pmatrix}
\]

By construction, this is surjective from \( T_{\tilde{\beta}(z)} \mathcal{X} \subset \mathbb{C}^{N+1} \) to \( \mathbb{C}^n \) at each point of \( \tilde{\beta}(\Gamma) \), if the approximation \( B \) is close enough. Moreover, it is clearly continuous. Therefore, \( \Lambda \) maps a neighborhood of the arc \( \tilde{\beta} \) in \( \mathcal{X} \) to \( \mathbb{C}^n \) biholomorphically, and its last coordinate is \( z_{N+1} \). This completes the proof. \( \square \)

### 3.4. Mildly Singular Arcs, Step I: Stein neighborhoods

The remaining part of this section is devoted to a proof of Theorem 2. The proof is in several steps. In this step we establish the existence of certain Stein neighborhoods \( \Omega_\delta \) of the arc \( \alpha([0, 1]) \). This allows us to solve \( \mathcal{F} \) equations in these neighborhoods. In the next step (subsection 3.5) we establish a result regarding the gluing together of immersions defined in neighborhoods of compact sets \( K_1 \) and \( K_2 \) in a manifold to a single immersion defined in a neighborhood of their union. We use these two results in subsection 3.6 to obtain a proof of Theorem 2.

The main result of this section is the following:

**Lemma 3.12.** Let \( \alpha : [0, 1] \to \mathcal{M} \) be a \( C^2 \) arc with mild singularities. Let \( P \subset [0, 1] \) be the set of points where \( \alpha \) is not smooth and let \( \phi \) be the good submersion associated
with $\alpha$. Let $U$ be a fixed neighborhood of $\alpha(P)$ in $\mathcal{M}$. For $\delta > 0$ sufficiently small there is a neighborhood $\Omega_\delta$ of $\alpha([0, 1])$ in $\mathcal{M}$ such that

- $\Omega_\delta$ is Stein,
- $\Omega_\delta$ contains the $\delta$-neighborhood of the arc $\alpha([0, 1])$, and
- away from the nonsmooth points $\alpha(P)$ of $\alpha$, the set $\Omega_\delta$ coincides with the $\delta$ neighborhood of the arc. More precisely, $\Omega_\delta \subset U \cup B_M(\alpha([0, 1]), \delta)$.

We will assume (without any loss of generality) that the points 0 and 1 are in $P$. We will need to use the following lemma which gives a simple condition for the union of two polynomially convex sets to be polynomially convex. A proof may be found in ([16], p. 386, Lemma 29.21(a)). $\hat{X}$ denotes the polynomial hull of a compact set $X \subset \mathbb{C}^N$.

**Lemma 3.13.** Let $X_1$ and $X_2$ be compact polynomially convex sets in $\mathbb{C}^n$ and let $p$ be a polynomial such that $\hat{p}(X_1) \cap \hat{p}(X_2) \subset \{0\}$. If $p^{-1}(0) \cap (X_1 \cup X_2)$ is polynomially convex, then $X_1 \cup X_2$ is again polynomially convex.

We will also require the following

**Observation 3.14.** Let $\gamma : [0, 1] \to \mathcal{M}$ be an arc, and let $0 < s < t < 1$. Suppose that in a neighborhood of $\gamma([0, t])$ is defined a strictly plurisubharmonic function $\nu \geq 0$ which vanishes precisely on the arc $\gamma$, and on a neighborhood of $\gamma([s, 1])$ is defined a continuous plurisubharmonic $\mu \geq 0$ which also vanishes precisely on $\gamma$. Further suppose that where both $\mu$ and $\nu$ are defined, $\mu < \nu$. Then there is a continuous plurisubharmonic $\lambda$ in a neighborhood of $\gamma([0, 1])$ such that $\lambda$ coincides with $\mu$ near $\gamma([0, s])$, with $\nu$ near $\gamma([t, 1])$, and is bounded above by $\nu$ near $\gamma([s, t])$.

**Proof.** Let $\psi \leq 0$ be a function of small $C^2$ norm such that

- $\nu + \psi$ is still plurisubharmonic.
- $\psi$ is 0 except in a small neighborhood of $\gamma(t)$, where it is negative.

We set

$$
\lambda = \begin{cases} 
\nu & \text{near } \gamma([1, s]) \\
\max(\mu, \nu + \psi) & \text{near } \gamma([s, t]) \\
\mu & \text{near } \gamma([t, 1])
\end{cases}
$$

This will be plurisubharmonic provided the definition makes sense. Now near $\gamma(s)$, we have $\lambda = \nu$ since $\mu < \nu$, so that $\lambda$ is continuous in a neighborhood of $\gamma([1, t])$. 

Near $\gamma(t)$, we have $\nu + \psi < 0$, consequently $\lambda = \mu$ there, and therefore $\lambda$ defines a continuous function in a neighborhood of $\alpha([0, 1])$. □

Now we prove Proposition 3.12. Let $p \in P$. In a neighborhood of $q = \alpha(p)$ we can find a system of coordinates $(z_1, \ldots, z_n)$ such that the last coordinate $z_n$ is equal to $\phi$. Now consider a polydisc $W$ of the type:

$$W = \{(z_1, \ldots, z_n) : |z_j| < R \text{ for } j = 1, \ldots, n-1; |z_n| < r\}$$

where $r$ and $R$ are so chosen that

- $r$ is much smaller than $R$,
- $W \subseteq V_q$, where $V_q$ is a polydisc centered at $q$ such that $V_q \subseteq U$.
- the arc $\alpha$ enters and exits $\overline{W}$ exactly once transversally through the part of the boundary $\partial W$ given by

$$\{(z_1, \ldots, z_n) : |z_j| < R \text{ for } j = 1, \ldots, n-1; |z_n| = r\}.$$  

That such $r$ and $R$ exist follows easily from the fact that $\phi \circ \alpha = z_n \circ \alpha$ is smooth.

Consider the compact set $K := \overline{W} \cup (\alpha([0, 1]) \cap \overline{V_q})$. This is the union of the polydisc $\overline{W}$ with two “whiskers” (the two components of $\alpha([0, 1]) \cap (\overline{V_q} \setminus W)$). The projection of $K$ on the last coordinate is of the form $\overline{B(0, r)} \cup \phi(\alpha(I))$ for a subinterval of $I$ of $[0, 1]$. By the choice of $r$ and $R$ above, this set is the disc $\overline{B(0, r)}$ attached with two arcs, each at exactly one point. Two applications of Lemma 3.13 (with $p = z_n$) shows that $K$ is polynomially convex. Applying Observation 3.10 to the polynomially convex $K$ and the continuous function $\text{dist}(\cdot, K)^2$ we obtain a continuous plurisubharmonic function $\mu \geq 0$ in a neighborhood of $\alpha(P)$ such that $\mu(z) \leq \text{dist}_{\mathcal{M}}(z, \alpha([0, 1]))^2$. Moreover, $\mu = 0$ exactly on a disjoint union of “Soup can with whiskers”-type of neighborhoods of the points of $\alpha(P)$. We take $\nu$ to be the square of the distance to $\alpha([0, 1])$. Then, applying Observation 3.14 to the plurisubharmonic $\mu$ and strictly plurisubharmonic $\nu$ (twice for each point of $\alpha(P)$) we can obtain a plurisubharmonic $\lambda$ such that $\lambda$ vanishes on the arc, and away from $\alpha(P)$ $\lambda = \nu$ the square of the distance. We now define $\Omega_\delta = \{Q \in \mathcal{M} : \lambda(Q) < \delta^2\}$. It is easily verified that $\Omega_\delta$ has the two geometric properties required, i.e. it contains the $\delta$-neighborhood of $\alpha([0, 1])$ and is actually the $\delta$-neighborhood away from $\alpha(P)$. To see that it is Stein, we note that for small $\delta$, the set $\Omega_\delta$ has the strictly plurisubharmonic exhaustion $(\delta^2 - \lambda)^{-1} + \rho$, where $\rho$ is a strictly
plurisubharmonic function in a neighborhood of $\alpha([0,1])$. (See Observation 3.9 above.)

3.5. **Mildly Singular Arcs, Step 2: Gluing of Immersions.** We now prove the induction step which we will use to glue locally defined coordinate maps to obtain a coordinate map in a neighborhood of a mildly singular arc.

Let $K_1$ and $K_2$ be given compact subsets of $\mathcal{M}$. Suppose we are given immersions $\Phi$ and $\Psi$ from neighborhoods of $K_1$ and $K_2$ respectively into $\mathbb{C}^n$. The main question considered in this step is whether there is an immersion from a neighborhood of the union $K = K_1 \cup K_2$ into $\mathbb{C}^n$. In the application, $K_1 \cup K_2$ will be a mildly singular arc without any singular points in $K_1 \cap K_2$.

3.5.1. **Hypotheses on the sets $K_1$, $K_2$ and the maps $\Phi$ and $\Psi$.** Of course to conclude that the immersions can be glued we need to add additional hypotheses. These hypotheses should correspond to the intended application. The ones that we will use are the following:

1. **Intersection is a smooth arc** The basic hypothesis is that the intersection $K_1 \cap K_2$ should be a smooth arc. More precisely, there is a $C^3$ arc $\alpha : [0,1] \to \mathcal{M}$ such that $K_1 \cap K_2$ is its image.

2. **Already glued in one coordinate ("Special")** We will assume that the two immersions have already been glued in one coordinate. More precisely, suppose that $\Phi$ and $\Psi$ are the immersions from neighborhoods of $K_1$ and $K_2$ into $\mathbb{C}^n$, then we will assume that the last coordinates $\Phi_n$ and $\Psi_n$ are equal in a neighborhood of the arc $K_1 \cap K_2$.

We will denote by $\phi$ the map from a neighborhood of $K$ into $\mathbb{C}$ which is equal to $\Phi_n$ near $K_1$ and $\Psi_n$ near $K_2$. In order to simplify the writing, we will say that a map whose last coordinate is $\phi$ is *special*. Therefore, the hypothesis is that there $\Phi$ and $\Psi$ are special. We will insist that while modifying $\Phi$ and $\Psi$ so that they become glued, the last coordinate is always $\phi$, i.e. they are special.

3. **Good submersion** We will assume that the map $\phi$ of the last paragraph is a good submersion associated with the arc $\alpha$. Further, the sets $\phi(K_2 \setminus K_1)$ and
\( \phi(K_1 \setminus K_2) \) are disjoint.

4. Ghost of (3.12) This hypothesis will be required in the last step of the proof. We assume that for small \( \delta > 0 \), and for a given relatively compact neighborhood \( U \) of \((K_1 \setminus K_2) \cup (K_2 \setminus K_1)\), there is a Stein open neighborhood \( \Omega_\delta \) of \( K \) which has the following properties.

- \( \Omega_\delta \) contains the \( \delta \)-neighborhood of \( K \).
- Near the arc \( K_1 \cap K_2 \), the set \( \Omega_\delta \) is in fact the \( \delta \) neighborhood. More precisely \( \Omega_\delta \subset U \cup B_M(K_1 \cap K_2, \delta) \). Consequently, there is a fixed compact \( H \) independent of \( \delta \) such that each \( \Omega_\delta \subset H \).

With these hypotheses we state the following proposition, whose proof will be given in §3.5.2 and §3.5.4 below.

**Proposition 3.15.** There is a special immersion \( \Xi \) from a neighborhood of \( K \) into \( \mathbb{C}^n \).

3.5.2. Step 1 of proof of Prop. 3.15 : Approximate gluing of special immersions. We fix the map \( \Phi \) and for each small \( \delta > 0 \) modify the special immersion \( \Psi \) to a new special immersion \( \Psi_\delta \) such that near the arc \( K_1 \cap K_2 \) the difference \( \Psi_\delta - \Phi \) is small. Once this “approximate solution” is obtained, in §3.5.4 we solve a standard Cousin problem to modify both \( \Phi \) and \( \Psi_\delta \) so that they now match on the intersection, and the result is an immersion.

We state the goal of this section as a proposition.

**Proposition 3.16.** After possibly shrinking the sets \( K_1 \) and \( K_2 \) (in a way so that their union \( K_1 \cup K_2 \) is always \( K \)), we can find a constant \( C > 0 \) such that for each \( \delta > 0 \) small a there is a special immersion \( \Psi_\delta \) into \( \mathbb{C}^n \) defined in a neighborhood of \( K_2 \) which contains the \( \delta \) neighborhood of \( K_1 \cap K_2 \), such that \( \| (\Psi_\delta')^{-1} \|_{op} < C \) and on \( B_M(K_1 \cap K_2, \delta) \) we have \( \| \Phi - \Psi_\delta \| = O(\delta^2) \).

For convenience, we divide the proof into a number of steps. Step 1. In this step we shrink \( K_1 \) and \( K_2 \) and modify \( \Psi \) to \( \tilde{\Psi} \) in such a way that the derivatives of the immersions \( \Phi \) and \( \Psi \) match at one point. This leads to a new transition function \( \tilde{\chi} \) with nicer properties.

By hypothesis (3) of §3.5.1 above, \( \phi \circ \alpha \) is a smooth embedded arc in \( \mathbb{C}^1 \) (where \( \phi \) is the common last coordinate of \( \Phi \) and \( \Psi \)). It follows that there is a neighborhood
$W$ of $K_1 \cap K_2 = \alpha([0,1])$ on which both $\Psi$ and $\Phi$ are injective, and therefore biholomorphisms onto the image of $W$.

After translating in $\mathbb{C}^n$, we can assume that $\Phi(\alpha(\frac{1}{2})) = 0$ and $\Psi(\alpha(\frac{1}{2})) = 0$. The transition map $\chi := \Phi \circ \Psi^{-1}$ from the open set $\Psi(W) \subset \mathbb{C}^n$ onto $\Phi(W) \subset \mathbb{C}^n$ is biholomorphic. Since each of $\Phi$ and $\Psi$ is special (that is, each has last coordinate equal to $\phi$) it follows that $\chi$ has the form $\chi(Z,w) = (\xi(Z,w), w)$ with $w \in \mathbb{C}$, and $Z, \xi(Z,w) \in \mathbb{C}^{n-1}$. Moreover, $0 \in W \cap \chi(W)$, in fact $\chi(0) = 0$.

Set $A = \chi'(0) \in \text{Mat}_{n \times n}(\mathbb{C})$. Define $\tilde{\Psi} := A \circ \Psi$. Then $\tilde{\Psi}$ is again a special immersion from a neighborhood of $K_2$ into $\mathbb{C}^n$, and its restriction to $W$ is a biholomorphic map onto the image. We can also define a new transition function $\tilde{\chi} := \Phi \circ \tilde{\Psi}^{-1} = \chi \circ A^{-1}$, which is a biholomorphism from $\tilde{\Psi}(W) \subset \mathbb{C}^n$ onto $\Phi(W) \subset \mathbb{C}^n$. This new $\tilde{\chi}$ has the same form as $\chi$, that is

\begin{equation}
\tilde{\chi}(Z,w) = (\tilde{\xi}(Z,w), w)
\end{equation}

where $w \in \mathbb{C}$, and both of $Z$ and $\tilde{\xi}(Z,w)$ are in $\mathbb{C}^{n-1}$. The additional feature (not present before) is that $\tilde{\chi}'(0) = I$.

The derivative of $\tilde{\chi}$ is given by

$$
\tilde{\chi}' = \begin{pmatrix}
\tilde{\xi}_Z & \tilde{\xi}_w \\
0 & 1
\end{pmatrix}
$$

where subscripts denote differentiation, with $\tilde{\xi}_Z \in GL_{n-1}(\mathbb{C})$ and $\tilde{\xi}_w$ a vector of $n-1$ components.

Since, $\tilde{\chi}'(0) = I$, we can shrink the compact sets $K_1$ and $K_2$ (while not changing their union $K$), and the neighborhood $W$ of $K_1 \cap K_2$, so that $\tilde{\chi}' \approx I$ on $\tilde{\Psi}(W)$, in the sense that there is a holomorphic $v : \tilde{\Psi}(W) \to \text{Mat}_{n-1 \times n-1}(\mathbb{C})$ such that on $\tilde{\Psi}(W)$, we have that

\begin{equation}
\tilde{\xi}_Z = \exp \circ v.
\end{equation}

**Step 2.** In this step we obtain, for $\delta > 0$ small, an approximation of the map $\tilde{\xi}$ of equation (8) by a by a map $\hat{\xi}_\delta$ affine in every coordinate except the last one, such that $\left\| \tilde{\xi}_\delta - \hat{\xi}_\delta \right\| = O(\delta^2)$ near the arc $\alpha$.

Let $\lambda = \tilde{\Psi} \circ \alpha$. Then $\lambda : [0,1] \to \tilde{\Psi}(W) \subset \mathbb{C}^n$ is a $C^3$ arc. The last coordinate $\lambda_n$ is the embedded $C^3$ arc $\phi \circ \alpha$. Denote its image $\lambda_n([0,1])$ by $\Gamma$. Since $\lambda_n$ is an
embedding, we can define a $C^3$ map $\gamma : \Gamma \to \mathbb{C}^{n-1}$ by setting

$$\gamma(\lambda_n(t)) := (\lambda_1(t), \ldots, \lambda_{n-1}(t))$$

Apply Lemma 3.5 it to $\gamma$. Hence, for $\delta > 0$ small, we can find a holomorphic $\gamma_\delta : B_{\mathbb{C}}(\Gamma, \delta) \to \mathbb{C}^{n-1}$ from the $\delta$ neighborhood $B_{\mathbb{C}}(\Gamma, \delta)$, of $\Gamma$ in $\mathbb{C}$ into $\mathbb{C}^{n-1}$ such that $\gamma_\delta$ is bounded in the $C^2$ norm on $B_{\mathbb{C}}(\Gamma, \delta)$, and on $\Gamma$, we have $\|\gamma_\delta - \gamma\| = O(\delta^2)$. We now define for small $\delta > 0$ a $\mathbb{C}^{n-1}$ valued holomorphic map $\hat{\xi}_\delta$ on the open set $\mathbb{C}^{n-1} \times B_{\mathbb{C}}(\Gamma, \delta) \subset \mathbb{C}^n$ by setting,

$$\hat{\xi}_\delta(Z, w) := \tilde{\xi}(\gamma_\delta(w), w) + \tilde{\xi}(\gamma_\delta(w), w)(Z - \gamma_\delta(w)).$$

$\hat{\xi}_\delta$ is the first order Taylor polynomial of the $\mathbb{C}^{n-1}$ valued map $\tilde{\xi}(\cdot, w)$ of $n-1$ variables around the point $\gamma_\delta(w) \in \mathbb{C}^{n-1}$.

We can rewrite $\hat{\xi}_\delta$ as

$$(10) \quad \hat{\xi}_\delta(Z, w) = f_\delta(w) + \exp g_\delta(w) Z$$

where $f_\delta$, $g_\delta$ are holomorphic maps defined on $B_{\mathbb{C}}(\Gamma, \delta)$. The $\text{Mat}_{(n-1) \times (n-1)}(\mathbb{C})$ valued map $g_\delta$ is given by

$$(11) \quad g_\delta(w) := v(\gamma_\delta(w), w)$$

where $v$ is as in equation (9) above, that is, $\xi_Z = \exp \circ v$. The $\mathbb{C}^{n-1}$ valued map $f_\delta$ is defined by

$$(12) \quad f_\delta(w) := \xi(\gamma_\delta(w), w) - (\exp g_\delta(w)) \gamma_\delta(w).$$

We now observe the following two facts which we will be use later.

1. $f_\delta$ and $g_\delta$ are bounded in $C^2$. Since on $B_{\mathbb{C}}(\Gamma, \delta)$, the map $\gamma_\delta$ is bounded in the $C^2$ norm independently of $\delta$, the same will be true of the functions $f_\delta$ and $g_\delta$. That is, there is a constant $C > 0$ independent of $\delta$ such that for $j = 0, 1, 2$ we have $\|f_\delta^{(j)}\| < C$ and $\|g_\delta^{(j)}\| < C$.

2. $\hat{\xi}_\delta - \hat{\xi}$ is small More precisely, suppose that the point $Z = (Z, w)$ is in the $\delta$ neighborhood $B_{\mathbb{C}^n}(\lambda([0,1]), \delta)$ of the arc $\lambda([0,1]) = \Psi(K_1 \cap K_2)$ in $\mathbb{C}^n$. Then we have

$$(13) \quad \|\hat{\xi}_\delta(Z) - \hat{\xi}(Z)\| = O(\delta^2).$$
To see this, note that $(Z,w) \in B_{C^n}(\lambda([0,1]),\delta)$ means that there is a $t \in \Gamma$ such that $\|Z - \gamma(t)\| < \delta$, and $|w - t| < \delta$. Therefore, using the properties of $\gamma_\delta$, we have
\[
\|Z - \gamma_\delta(w)\| \leq \|Z - \gamma(t)\| + \|\gamma(t) - \gamma_\delta(t)\| + \|\gamma'_\delta\|_{\sup} |t - w| \\
\leq \delta + O(\delta^{\frac{5}{2}}) + C\delta = O(\delta).
\]

Now applying Taylor’s theorem to the first order Taylor polynomial $\hat{\xi}_\delta(\cdot, w)$ of $\tilde{\xi}(\cdot, w)$ around the point $\gamma_\delta(w)$, we see that
\[
\|\hat{\xi}_\delta(Z, w) - \tilde{\xi}(Z, w)\| = O(\|Z - \gamma_\delta(w)\|^2) = O(\delta^2).
\]

Step 3. We now construct an approximation $\chi_\delta$ of $\tilde{\chi}$.

At this point we require to use a lemma regarding the approximation of functions of one variable. In order not to interrupt the flow of the proof we state it here, but postpone its proof to §3.5.3.

**Lemma 3.17.** Let $B_1$, $B_2$ and $B_3$ be compact subsets of $\mathbb{C}$ such that $B_1 \cap B_3 = \emptyset$ and $B_1 \cap B_2$ is a single point, which we call $z_0$. Let $0 < \theta < 1$ and let $p$ be a positive integer. Then if $L$ is a closed subset of $B_1$ such that $L \cap B_2 = \emptyset$ (that is, $z_0 \notin L$), then there is a constant $C$ with the following property. For $\delta > 0$ small, if $f$ is a holomorphic function in the closed $\delta$-neighborhood $B_\mathbb{C}(B_1 \cup B_2, \delta)$ of $B_1 \cup B_2$ such that
\[
\|f\|_{C^1(B_\mathbb{C}(B_1 \cup B_2, \delta))} \leq 1,
\]
then there is a holomorphic $f_\delta$ defined in the $\delta$ neighborhood of $B := B_1 \cup B_2 \cup B_3$ such that
\[
\|f_\delta\|_{C^1(B_\mathbb{C}(B, \delta))} \leq C
\]
and on $B_\mathbb{C}(L, \delta)$ we have
\[
|f - f_\delta| < C\delta^p.
\]

To apply Lemma 3.17 to our situation, we will let $p = 2$, $B_1 = \lambda_n([0, \frac{2}{3}])$, $L = \lambda_n([0, \frac{1}{2}]) \subset B_1$ and $B_2 = \lambda_n([\frac{2}{3}, 1])$. Then as required, we have that $B_1 \cap B_2$ a single point $z_0 = \lambda_n(\frac{3}{4})$, and $z_0 \notin L$. Also, we have $B_1 \cup B_2 = \lambda_n([0, 1]) = \Gamma$. For $B_3$ we take a relatively compact neighborhood of $\phi(K_2 \setminus K_1)$ such that $B_1 \cap B_3 = \emptyset$. Then $\bar{B} = B_1 \cup B_2 \cup B_3 \supset \phi(K_2)$.

Now the holomorphic functions $f_\delta$ and $g_\delta$ defined in equations (12) and (13) above are holomorphic in the closed delta neighborhood of $\Gamma = B_1 \cup B_2$. Moreover, thanks
to the $C^2$ boundedness of the maps, for any $\theta$ with $0 < \theta < 1$ we actually have $\| f_\delta \|_{C^{1,\theta}(B_C(B_1 \cup B_2, \delta))}$ and $\| g_\delta \|_{C^{1,\theta}(B_C(B_1 \cup B_2, \delta))}$ bounded independently of $\delta$.

Therefore, by an application of Lemma 3.17 we get holomorphic maps $F_\delta$ and $G_\delta$, defined on the $\delta$ neighborhood $A_\delta$ of $B = \Gamma \cup B_3$, such that $\{F_\delta\}$ and $\{G_\delta\}$ are uniformly bounded in the $C^2$ norm independent of $\delta$, and on the set $B_C(\lambda_n([0, \frac{1}{2}]), \delta)$ we have $\| F_\delta - f_\delta \| = O(\delta^2)$ and $\| G_\delta - g_\delta \| = O(\delta^2)$.

We shrink the sets $K_1$ and $K_2$ again so that $K_1 \cap K_2 = \alpha([0, \frac{1}{2}])$. We now define the map $\xi_\delta$ from $\mathbb{C}^{n-1} \times A_\delta$ into $\mathbb{C}^{n-1}$ by

$$\xi_\delta(Z, w) := F_\delta(w) + (\exp G_\delta(w)) Z,$$

and let

$$\chi_\delta(Z, w) := (\xi_\delta(Z, w), w)$$

We now observe the following properties of the maps $\chi_\delta$ and $\xi_\delta$

- $\xi_\delta(Z, w)$ (and consequently $\chi_\delta(Z, w)$) is defined on the set $\mathbb{C}^{n-1} \times A_\delta$ which contains a neighborhood of $\tilde{\Psi}(K_2)$ in $\mathbb{C}^n$.

- $\chi_\delta$ is a biholomorphic automorphism of the set $\mathbb{C}^{n-1} \times A_\delta$, and there is a constant $C > 0$ independent of $\delta$ so that

$$\left\| (\chi_\delta^{-1})' \right\|_{op} < C.$$ 

The derivative of $\chi_\delta$ is of the form

$$\chi_\delta'(Z, w) = \begin{pmatrix} \exp G_\delta(w) & * \\ 0 & 1 \end{pmatrix},$$

showing that $\chi_\delta'$ is a local biholomorphism. Now suppose that $Z' \in \mathbb{C}^{n-1}$ and $w' \in A_\delta$. Then we can solve the equation $\chi_\delta(Z, w) = (Z', w')$ explicitly to obtain the representations $Z = \exp(-G_\delta(w')) (Z' - F_\delta(w'))$ and $w = w'$. This shows that $\chi_\delta$ is a biholomorphism, and its inverse is given by

$$\chi_\delta^{-1}(Z, w) = (\exp(-G_\delta(w)) (Z - F_\delta(w)), w).$$

By construction each of $F_\delta$ and $G_\delta$ is bounded in the $C^1$ norm, independently of $\delta$. The bound follows immediately.

- In the $\delta$ neighborhood $B_C(\tilde{\Psi}(K_1 \cap K_2), \delta)$ of $\tilde{\Psi}(K_1 \cap K_2)$ we have that

$$\| \bar{\chi} - \chi_\delta \| = O(\delta^2)$$
This follows immediately from the fact that the coefficients \( F_\delta \) and \( \exp G_\delta \) of \( \xi_\delta \) are \( O(\delta^2) \) perturbations of the coefficients \( f_\delta \) and \( \exp g_\delta \) of \( \hat{\xi}_\delta \).

Step 4. \textit{End of the proof of Proposition 3.16}. We now define the promised map

\[ \Psi_\delta := \chi_\delta \circ \tilde{\Psi}. \]

We observe that

- By construction \( \chi_\delta \) is a biholomorphic map from the set \( \mathbb{C}^{n-1} \times A_\delta \) into itself. Recall that \( A_\delta = B_\mathbb{C}(\phi(K_1 \cap K_2), \delta) \cup L \), where \( L \) is a fixed compact neighborhood of \( \phi(K_2 \setminus K_1) \subset \mathbb{C} \), such that \( L \cap \phi(K_1 \cap K_2) \) is a single point. It easily follows from this that \( \Psi_\delta \) is defined on a set of the form \( B_M(K_1 \cap K_2, \delta) \cup U \), where \( U \) is a fixed (independent of \( \delta \) ) neighborhood of \( K_2 \setminus K_1 \).
- \( \Psi_\delta^{-1} \) and \( \tilde{\Psi}^{-1} \) exist locally, and satisfy the equation \( \Psi_\delta^{-1} = \tilde{\Psi}^{-1} \circ \chi_\delta^{-1} \). Using the chain rule and using the fact that \( \|(\chi_\delta^{-1})'\|_{\text{op}} \leq C \) for a \( C \) independent of \( \delta \) proved above we see that there is a constant \( C' \) independent of \( \delta \) such that \( \|(\Psi_\delta^{-1})'\|_{\text{op}} < C' \). Another application of the chain rule gives us \( \|(\Psi_\delta')^{-1}\|_{\text{op}} < C' \).
- On the \( \delta \) neighborhood \( B_M(K_1 \cap K_2, \delta) \) of \( K_1 \cap K_2 \), we have \( \|\Phi - \Psi_\delta\| = O(\delta^2) \).

This completes the proof of Proposition 3.16, except we still need to prove Lemma 3.17. \( \square \)

3.5.3. \textit{Proof of Lemma 3.17}. We need now to prove Lemma 3.17. We will require the following fact, a proof of which can be found in [15]. The notation \( \mathcal{C}^{k,\theta}(K) \) denotes the space of functions on \( K \) whose \( k \)-th order derivatives are Hölder continuous with exponent \( \theta \).

We let \( C \) stand for any constant not depending on \( \delta \). The proof will be in two very similar steps, each of which will involve the solution of a \( \overline{\partial} \) problem in one variable.

Step 1. The aim of the first step is to construct a holomorphic function \( g_\delta \) on the \( \delta \)-neighborhood of \( B = B_1 \cup B_2 \cup B_3 \) with the following properties.

- The \( \mathcal{C}^1 \) norm of \( g_\delta \) is bounded independently of \( \delta \), that is \( \|g_\delta\|_{\mathcal{C}^1(B_c(B,\delta))} \leq C \), where \( C \) is independent of \( \delta \).
By hypothesis that the intersection $B_1 \cap B_2$ is a single point $z_0$. Denote henceforth the disc $B_C(z_0, \delta)$ by $N_\delta$, and the holomorphic function $f - g_\delta$ (defined on a neighborhood of $B_1 \cup B_2$) by $k_\delta$. Then $\|k_\delta\|_{C^{1,\theta}(N_\delta)} = O(\delta^{p+2})$.

To construct $g_\delta$ let $\psi$ be a $C^\infty$ cutoff on $\mathbb{C}$ which is 1 on a neighborhood of $B_1$ (therefore in a neighborhood of the point $z_0$) and 0 on a neighborhood of $B_3$. We now set

$$\lambda_\delta(z) := \frac{1}{(z - z_0)^{p+4}} \frac{\partial \psi}{\partial z} f(z).$$

Observe that $\lambda_\delta$ is defined on the closed $\delta$ neighborhood $\overline{B_C(B_1 \cup B_2)}$ of $B_1 \cup B_2$ (and this justifies the subscript $\delta$ on $\lambda$.) After extending by 0 at points where $\psi = 0$, we can assume that $\lambda_\delta$ is defined and smooth on $\overline{B_C(B, \delta)}$. Moreover, since $f$ is bounded by 1 in the $C^{1,\theta}$ norm, it follows that there is a constant $C$ (independent of $\delta$), so that $\|\lambda_\delta\|_{C^{1,\theta}(\overline{B_C(B_1 \cup B_2)})} < C$.

Thanks to Lemma 2.1 there is a compactly supported extension $\tilde{\lambda}_\delta$ of $\lambda_\delta$ to $\mathbb{C}$ such that $\|\tilde{\lambda}_\delta\|_{C^{1,\theta}(\mathbb{C})} \leq C$ (with $C$ independent of $\delta$).

We now define $g_\delta := \psi f + (z - z_0)^{p+4} \left( -\frac{1}{\pi z} * \tilde{\lambda}_\delta \right)$, where $\psi f$ is assumed to be 0 where $\psi = 0$. Then

- $g_\delta$ is holomorphic in the $\delta$-neighborhood of $B$,
- since $\tilde{\lambda}_\delta$ is bounded in the $C^{1,\theta}$ norm, it follows that $\|g_\delta\|_{C^{1,\theta}(\overline{B_C(B, \delta)})} \leq C$, where $C$ is independent of $\delta$,
- for small enough $t$ we have $k_\delta(z_0 + t) = t^{p+4} \left( -\frac{1}{\pi z} * \lambda \right)$. The first factor $t^{p+4}$ is $O(\delta^{p+2})$ in the $C^2$ norm on the disc $N_\delta$. The second term is bounded on this disc in the $C^{1,\theta}$ norm. Therefore, we easily have

$$(17) \quad \|k_\delta\|_{C^{1,\theta}(N_\delta)} = O(\delta^{p+2}).$$

Therefore, the function $g_\delta$ and $k_\delta = f - g_\delta$ satisfy the conditions stated in the beginning of this step.

Step 2. Now we write $f = k_\delta + g_\delta$. Observe that $g_\delta$ is already defined in the $\delta$-neighborhood of $B = B_1 \cup B_2 \cup B_3$. To approximate $f$ we will approximate $k_\delta = f - g_\delta$ (which is holomorphic on the $\delta$-neighborhood of $B_1 \cup B_2$) by a holomorphic function $h_\delta$ defined in the $\delta$ neighborhood of $B$. We will set $f_\delta = h_\delta + g_\delta$. Then, for $f_\delta$ to satisfy the conclusion of Lemma 3.17 it is sufficient that

- $\|h_\delta\|_{C^1(\overline{B_C(B, \delta)})}$ is bounded independently of $\delta$. 

• on the set $B_C(L, \delta)$ (where as in the hypothesis $L$ is a fixed subset of $B_1$ not containing the point $z_0$) we have $|h_\delta - k_\delta| = O(\delta^p)$.

To construct $h_\delta$ we proceed as follows. For $\delta > 0$ small, there is a $C^\infty$ function $\alpha_\delta$ defined on the closed $\delta$ neighborhood of $B$ such that

• $0 \leq \alpha_\delta \leq 1$, with $\alpha_\delta \equiv 1$ on the neighborhood of the set $L$, and $\alpha_\delta \equiv 0$ on a fixed neighborhood of $B_3$, and
• $\nabla \alpha_\delta$ is supported in $N_\delta = B_C(z_0, \delta)$ and furthermore, $\alpha_\delta$ satisfies (18)

$\|\alpha_\delta\|_{C^2(N_\delta)} = O\left(\frac{1}{\delta^2}\right)$.

Now define a smooth function $\mu_\delta$ on $B_C(B, \delta)$ by setting $\mu_\delta := \frac{\partial \alpha_\delta}{\partial z} \cdot k_\delta$, and extending by 0 outside $N_\delta$. Thanks to equations (18) and (17), it follows that $\|\mu_\delta\|_{C^1,\theta(B_C(B, \delta))} = O(\delta^p)$. An application of Lemma 2.1 leads to the construction of a compactly supported extension $\tilde{\mu}_\delta$ of $\mu_\delta$ to the whole of $\mathbb{C}$ such that

$\|\tilde{\mu}_\delta\|_{C^1,\theta(\mathbb{C})} = O(\delta^p)$.

We can assume that the supports of the $\tilde{\mu}_\delta$’s lie in a fixed compact of $\mathbb{C}$ (independently of $\delta$).

Define a holomorphic $h_\delta$ on the $\delta$ neighborhood $B_C(B, \delta)$ by setting

$h_\delta := \alpha_\delta \cdot k_\delta + \left(-\frac{1}{\pi z} * \tilde{\mu}_\delta\right)$

where $\alpha_\delta \cdot k_\delta$ is understood to be 0 if $\alpha_\delta = 0$ (even if $k_\delta$ is not defined). It is clear that $\|h_\delta\|_{C^1(B_C(B, \delta))} \leq C$.

Now consider the $\delta$ neighborhood $B_C(L, \delta)$ of the set $L$. For small $\delta$, we have $\alpha_\delta \equiv 1$ on this set. Then on $B(L, \delta)$ we have

$|h_\delta - k_\delta| = \left|\frac{1}{\pi z} * \tilde{\mu}_\delta\right| = O(\delta^p)$.

This ends the proof of Lemma 3.17. □

3.5.4. End of the proof of Prop. 3.15 : A Cousin problem on a neighborhood of $K_1 \cup K_2$.

**Lemma 3.18.** For $\delta > 0$ small, there are holomorphic maps $H_1^\delta$ and $H_2^\delta$ from neighborhoods of $K_1$ and $K_2$ respectively into $\mathbb{C}^n$, such that

• in a neighborhood of $K_1 \cap K_2$, we have $\Phi + H_1^\delta = \Psi_\delta + H_2^\delta$,
• for \( j = 1, 2 \) we have \( \| (H^\delta_2)' \|_{op} = O(\delta^2) \), and
• the last coordinates of \( H^\delta_1 \) and \( H^\delta_2 \) are both 0.

We note that this completes the proof of Proposition 3.15. Consider the map \( \Xi \) defined in a neighborhood of \( K = K_1 \cup K_2 \) by

\[
\Xi = \begin{cases} 
\Phi + H^\delta_1 \quad \text{near } K_1 \\
\Psi_\delta + H^\delta_2 \quad \text{near } K_2
\end{cases}
\]

This is a well defined special holomorphic map. To show that it is an immersion, it is sufficient to show that the derivative \( \Xi'(Z) \) is an isomorphism of vector spaces for \( Z \) near \( K \). Near \( K_2 \) we have \( \Xi'(Z) = \Psi_\delta' \left( \frac{1}{\delta^2} + \left( H^\delta_2 \right)' \right) \), but \( \| (\Psi_\delta)'^{-1} \|_{op} \leq C \) (with \( C \) independent of \( \delta \)), and \( \| (H^\delta_2)' \|_{op} = O(\delta^2) \), so for small \( \delta \), the linear operator \( \Xi' \) is an isomorphism. The same conclusion holds in a neighborhood of \( K_1 \) for \( \Xi = \Phi + H^\delta_1 \).

The proof of 3.18 will require the following two lemmas:

**Lemma 3.19.** Let \( \mathcal{M} \) be Stein and let \( \Omega \subset \mathcal{M} \) be open. There is a constant \( C \) with the following property. Let \( U \subset \Omega \), where \( U \) is a Stein open subset of \( \mathcal{M} \), and let \( g \) be a smooth \( \overline{\partial} \)-closed \((0,1)\)-form on \( U \) which is in \( L^2_{(0,1)}(U) \). Then there is a smooth \( u : \Omega \rightarrow \mathbb{C} \) such that \( \overline{\partial} u = g \) and \( u \) satisfies the estimate

\[
(19) \quad \| u \|_{L^2(U)} \leq C \| g \|_{L^2_{(0,1)}(U)}
\]

The point of the lemma is that the constant \( C \) does not depend on the open set \( U \), but only on the relatively compact \( \Omega \). This is well known in the case when \( \mathcal{M} = \mathbb{C}^n \) (see e.g. [1]). The general case may be reduced to the Euclidean case by embedding \( \mathcal{M} \) in some \( \mathbb{C}^N \) (for details see [3]).

**Lemma 3.20.** let \( \Omega \subset \mathcal{M} \) be a smoothly bounded domain. Then, there is a constant \( C \) such that for any smooth function \( w : \Omega \rightarrow \mathbb{C} \), and any compact \( K \subset \Omega \) we will have the inequality:

\[
(20) \quad \sup_K |w| \leq C \left\{ \frac{1}{\text{dist}(K, \Omega^c)} \| w \|_{L^2(\Omega)} + \text{dist}(K, \Omega^c) \| \overline{\partial} w \|_{L^\infty(\Omega)} \right\}
\]

**Proof.** After using local co-ordinates and scaling, we can see that it is sufficient to establish the following inequality for smooth functions \( w \) defined on the closed unit ball \( B \) in \( \mathbb{C}^n \):

\[
|w(0)| \leq K \left\{ \| w \|_{L^2(B)} + \sup_B \left( \max_j \left| \frac{\partial w}{\partial z_j} \right| \right) \right\}
\]
This is proved in [1] (p. 130, Lemma 16.7) □

Now we prove Proposition 3.18.

Proof. For convenience of notation, we will suppress $\delta$ whenever possible, and write $\Phi = (\hat{\Phi}, \phi), \Psi = (\hat{\Psi}, \phi)$, and $H^j_\delta = (h_j, 0)$, where $\hat{\Phi}, \hat{\Psi}$ and $h_j$ are all $\mathbb{C}^{n-1}$-valued. Then the result is equivalent to solving the $\mathbb{C}^{n-1}$ valued additive Cousin problem

\[ h_1 - h_2 = \hat{\Psi} - \hat{\Phi} := R_\delta \]

with bounds on $h_1$ and $h_2$. We do this using the well known standard method. It is clear that $(K_1 \setminus K_2) \cap (K_2 \setminus K_1) = \emptyset$, and therefore, we can find a smooth cutoff $\mu$ in a neighborhood of $K_1 \cup K_2$ such that $\mu$ is 1 in a neighborhood of $K_1 \setminus K_2$ and 0 in a neighborhood of $K_2 \setminus K_1$. We get a smooth solution to the Cousin problem given by

\[
\begin{align*}
\tilde{h}_1 &= \mu R_\delta \text{ extended by 0 where } \mu = 0 \\
\tilde{h}_2 &= (\mu - 1) R_\delta \text{ extended by 0 where } \mu = 1
\end{align*}
\]

Observe that $\|\tilde{h}_j\| = O(\delta^2)$ for $j = 1, 2$.

We want a “correction” $u$, defined in a neighborhood of $K_1 \cup K_2$, so that $h_j = \tilde{h}_j + u$ will be holomorphic, that is, we want to solve the equations $\overline{\partial}(\tilde{h}_j + u) = 0$. Both of these equations are equivalent to the $\overline{\partial}$ equation in a neighborhood of $K_1 \cup K_2$ given by

(21) $\overline{\partial}u = g,$

where $g$ is a $\mathbb{C}^{n-1}$ valued $(0,1)$ form (defined below) on a Stein neighborhood $\Omega_\delta$ of $K_1 \cup K_2$ of the type whose existence was assumed in the hypotheses, that is, $\Omega_\delta$ contains a $\delta$-neighborhood of $K_1 \cup K_2$, and is the $\delta$-neighborhood near $K_1 \cap K_2$. The smooth form $g$ is defined by $g := -R_\delta \overline{\partial} \mu$ on the $\delta$ neighborhood of $K_1 \cap K_2$, and is extended by 0 to $\Omega_\delta$. We therefore have

\[
\|g\|_{L^2((0,1),\Omega_\delta)} \leq \|g\|_{L^\infty}(\text{Vol(support } g))^{\frac{1}{2}} \\
= O(\delta^2)(O(\delta^{2n-1}))^{\frac{1}{2}} = O(\delta^{n+\frac{3}{2}}).
\]

Using Lemma 3.19 we obtain a function $u$ on $\Omega_\delta$ such that for some $C$ independent of $\delta$,

\[
\|u\|_{L^2(\Omega_\delta)} \leq C \|g\|_{L^2((0,1),\Omega_\delta)} \leq C\delta^{n+\frac{3}{2}}.
\]
For convenience, denote the $\delta$ neighborhood of $K = K_1 \cup K_2$ by $K_{\delta}$. Then, by hypothesis, $K_{\delta} \subset \Omega_{\delta}$, and it follows that $\text{dist} \left( K_{\frac{\delta}{2}}, \Omega_{\delta}^c \right) \geq \frac{\delta}{2}$. We apply now inequality 20 of Chapter 1 to $u$, to conclude that

$$\|u\|_{L^\infty(K_{\frac{\delta}{2}})} \leq C \left\{ \frac{1}{\text{dist} \left( K_{\frac{\delta}{2}}, \Omega_{\delta}^c \right)} \right\} \|u\|_{L^2(\Omega_{\delta})} + \|\nabla u\|_{L^\infty(\Omega_{\delta})} \leq C \delta^{\frac{3}{2}}.$$  

Now, define $h_j = \tilde{h}_j + u$. Then we have $\|h_j\| \leq C\delta^2 + C\delta^{\frac{3}{2}}$. Therefore, on $K_{\frac{\delta}{2}}$, we have $\|h_j\| = O(\delta^{\frac{3}{2}})$. Applying the Cauchy estimate, the required bound on $h'_j$ (and therefore $(H_{\delta}^j)'$) follows. 

3.6. Mildly singular arcs, Step 3: End of proof of Theorem 2. Let $\alpha : [0,1] \to \mathcal{M}$ be a mildly singular arc, and let $\phi$ be the associated good submersion into $\mathbb{C}$. We begin by covering the compact set $\alpha([0,1])$ by a finite cover of open sets $\{U_i\}_{i=1}^N$ such that

1. on each $U_i$ is defined a coordinate map whose last coordinate is $\phi$, and
2. the parts of the arc $\alpha$ in the intersections $U_i \cap U_{i+1}$ are all smooth.

A simple induction argument applied to this cover shows that it is sufficient to consider the case when $\alpha([0,1])$ is covered by charts $U$ and $V$, such that there are coordinates $\Phi : U \to \mathbb{C}^n$, $\Psi : V \to \mathbb{C}^n$, each having last coordinate $\phi$. On the intersection, $\alpha$ is $C^3$, and $\phi \circ \alpha : [0,1] \to \mathbb{C}$ is a $C^3$ arc. Thanks to Theorem 3.12 we have for small $\delta > 0$, Stein neighborhoods $\Omega_{\delta}$ exactly of the type required. Therefore, we obtain an immersion $\Xi$ from a neighborhood of $\alpha([0,1])$ into $\mathbb{C}^n$, whose last coordinate is $\phi$. But $\phi \circ \alpha$ is injective, so that $\Xi$ is also injective near $\alpha([0,1])$, that is, there is a neighborhood of the arc on which $\Xi$ is a biholomorphism. 

□

4. Approximation of Maps into Complex Manifolds

We will continue to denote by $\mathcal{M}$ a complex manifold of complex dimension $n$ which has been endowed with a Riemannian metric (as before, the actual choice of the metric will be irrelevant.) In analogy with the notation of Section 2 we introduce the following conventions. For a compact $K \subset \mathbb{C}$, the notation $\mathcal{H}(K, \mathcal{M})$ denotes the space of holomorphic maps from $K$ to $\mathcal{M}$. A map $f : K \to \mathcal{M}$ is in $\mathcal{H}(K, \mathcal{M})$.
iff there is an open set \( U_f \) in \( \mathbb{C} \) with \( K \subset U_f \) and a holomorphic \( F : U_f \to M \), such that \( F \) restricts to \( f \) on \( K \). By \( \mathcal{A}^k(K, M) \) we denote the closed subspace of \( \mathcal{C}^k(K, M) \) consisting of those maps which are holomorphic in the topological interior \( \text{int} \, K \) of the compact set \( K \). The space \( \mathcal{A}^k(K, M) \) will always be considered to have the topology inherited from \( \mathcal{C}^k(K, M) \). When \( M \) is the complex plane \( \mathbb{C} \) we will abbreviate \( \mathcal{H}(K, \mathbb{C}) \) and \( \mathcal{A}^k(K, \mathbb{C}) \) by \( \mathcal{H}(K) \) and \( \mathcal{A}^k(K) \) respectively.

By a Jordan domain \( \Omega \) in the plane, we mean a domain whose boundary \( \partial \Omega \) consists of finitely many Jordan curves (homeomorphic images of circles in the place). A Jordan domain is said to be circular if each component of \( \partial \Omega \) is a circle in the plane. A \( C^1 \) domain is a Jordan domain in which each component of \( \partial \Omega \) is a \( C^1 \) embedded image of a circle.

We now state the approximation results in our new notation.

**Theorem 3.** Let \( \Omega \subset \mathbb{C} \) be a Jordan domain. Then \( \mathcal{H}(\overline{\Omega}, M) \) is dense in \( \mathcal{A}^0(\overline{\Omega}, M) \).

For an analogous result for \( \mathcal{C}^k \) maps with \( k \geq 1 \), we have to assume more regularity on the boundary:

**Theorem 4.** Let \( \Omega \subset \mathbb{C} \) a \( C^1 \) domain, i.e. it is bounded by finitely many \( C^1 \) Jordan curves. If \( k \geq 1 \), the space \( \mathcal{H}(\overline{\Omega}, M) \) is dense in \( \mathcal{A}^k(\overline{\Omega}, M) \).

Before we proceed to prove Theorems 3 and 4, we will show that the boundary regularity required in 3 can be reduced. We will show that in Theorem 3 it is sufficient to consider the case when \( \Omega \) is a circular domain, i.e. it is sufficient to prove the following:

**Theorem 3'** For a circular domain \( W \), the subspace \( \mathcal{H}(\overline{W}, M) \) is dense in \( \mathcal{A}^0(\overline{W}, M) \).

We will require the following two facts from the theory of conformal mapping:

(a) (Köbe) Let \( \Omega \) be a Jordan domain. Then there is a circular domain which is conformally equivalent to \( \Omega \).

(b) (Carathéodory) Let \( \Omega_1 \) and \( \Omega_2 \) be finitely connected Jordan domains, and \( f : \Omega_1 \to \Omega_2 \) a biholomorphism. Then \( f \) extends to a homeomorphism from \( \Omega_1 \) onto \( \Omega_2 \). (See, for example, [17], Theorems IX.35 and IX.2 respectively. In this reference (b) is stated for simply connected domains but the proof readily extends to the multiply connected case)

**Lemma 4.1.** Theorem 3 and Theorem 3' are equivalent.

**Proof.** It is clear that Theorem 3 implies Theorem 3', since a circular domain is also a Jordan domain. For the converse we proceed as follows. Let \( \Omega \) be a
Jordan domain. Thanks to the two facts from the theory of conformal mapping mentioned before this proposition, it follows that there is a circular domain \( W \) such that there is a homeomorphism \( \chi : \overline{\Omega} \to \overline{W} \) which maps \( \Omega \) conformally onto \( W \). Let \( f \in A^0(\overline{\Omega}, \mathcal{M}) \). Then \( f \circ \chi^{-1} \) is in \( A^0(\overline{W}, \mathcal{M}) \), so by hypothesis we can approximate it uniformly by functions \( g \in H(\overline{W}, \mathcal{M}) \). Since \( \chi \in A^0(\overline{\Omega}, \mathcal{C}) \), thanks to a version of Mergelyan’s theorem (see [6], Theorem 12.2.7.), it can be approximated uniformly on \( \overline{\Omega} \) by functions \( \tilde{\chi} \in H(\overline{\Omega}, \mathcal{C}) \). Therefore, \( g \circ \tilde{\chi} \) is a holomorphic map defined in a neighborhood of \( \Omega \) which approximates \( f \) uniformly. This establishes the lemma. \( \square \)

4.1. Approximation on Good Pairs. This section is devoted to the development of some tools which will be used in \( \S 4.2 \) (along with the results of Section 3. We begin with a few definitions.

**Definition 4.2.** We say that a pair \((K_1, K_2)\) of compact subsets of \( \mathbb{C} \) is a *good pair* if the following hold:

(A) \( K_1 \) and \( K_2 \) are “well-glued” together in the sense that

\[
K_1 \setminus K_2 \cap K_2 \setminus K_1 = \emptyset.
\]

(B) \( K_1 \cap K_2 \) has finitely many connected components, each of which is star shaped.

We now state the basic approximation result which will be used in the proof of Theorems 3 and 4.

**Theorem 5.** Let \((K_1, K_2)\) be a good pair of compact sets, and let \( V \) be a compact subset of \( \mathbb{C} \) disjoint from \( K_1 \) such that the following holds. For a fixed \( k \geq 0 \), given any \( g \in A^k(K_2, \mathbb{C}) \) and an \( \eta > 0 \), there is a \( g_{\eta} \in A^k(K_2 \cup V, \mathbb{C}) \) such that \( \|g - g_{\eta}\|_{C^k(K_2)} < \eta \).

Let \( f \in A^k(K_1 \cup K_2, \mathcal{M}) \) be such that each of the sets \( f(K_j) \), for \( j = 1, 2 \) is contained in a coordinate neighborhood of \( \mathcal{M} \). Then, given \( \epsilon > 0 \) there is an \( f_\epsilon \in A^k(K_1 \cup K_2, \mathcal{M}) \) such that \( \text{dist}_{C^k(K_1 \cup K_2, \mathcal{M})}(f, f_\epsilon) < \epsilon \), and \( f_\epsilon \) extends as a holomorphic map to a neighborhood of \((K_2 \cap V)\).

Of course this is of interest only in the case when \( K_2 \cap V \neq \emptyset \). We split the proof into several steps.

**Observation 4.3.** *(Additive Cousin problem \( C^k \) to the boundary.)* Let \((K_1, K_2)\) be a good pair. For each \( k \geq 0 \), there exist bounded linear maps \( T_j : A^k(K_1 \cap K_2, \mathbb{C}) \to \)
\( A^k(K_j, \mathbb{C}) \) such that for any function \( f \) in \( A^k(K_1 \cap K_2, \mathbb{C}) \) we have on \( K_1 \cap K_2 \),
\begin{equation}
T_1 f + T_2 f = f,
\end{equation}

Proof. We reduce the problem to a \( \bar{\partial} \) equation in the standard way. Let \( \chi \) be a smooth cutoff which is \( 1 \) near \( K_1 \setminus K_2 \) and \( 0 \) near \( K_2 \setminus K_1 \). Let \( \lambda := f \frac{\partial f}{\partial \bar{z}} \), so that \( \lambda \in A^k(K_1 \cap K_2, \mathbb{C}) \). Let \( 0 < \theta < 1 \). Thanks to Lemma \ref{lemma}, there is a bounded linear extension operator \( E : C^k(K_1 \cap K_2) \to C^{k-1,\theta}(\mathbb{R}^2) \), such that each for \( g \), the extension \( Eg \) is supported in a fixed compact set of \( \mathbb{R}^2 \). We can now define \( T_1 f = (1 - \chi).f + \frac{1}{\pi z} \ast (E\lambda) \), and \( T_2 f = \chi.f - \frac{1}{\pi z} \ast (E\lambda) \), where \( (1 - \chi).f \) (resp. \( \chi.f \)) is assumed to be \( 0 \) at points where \( \chi = 0 \) (resp. \( (1 - \chi) = 0 \)) even if \( f \) is not defined. Since for \( U \Subset \mathbb{C} \), the map \( v \mapsto \frac{1}{z} \ast v \) is bounded from \( C^{k-1,\theta}(U) \) to \( C^{k,\theta}(\mathbb{C}) \), the result follows.

We use Observation \ref{observation} to prove a version of the Cartan Lemma on factoring matrices similar to one found in \cite{1}, pp. 47-48.

Lemma 4.4. Let \( (K_1, K_2) \) be a good pair, and let \( g \in A^k(K_1 \cap K_2, GL_n(\mathbb{C})) \), where \( k \geq 0 \). Then, for \( j = 1, 2 \) there are \( g_j \in A^k(K_j, GL_n(\mathbb{C})) \) such that \( g = g_2 \cdot g_1 \) on \( K_1 \cap K_2 \).

Proof. Denote by \( \mathcal{G}_j \) the group \( A^k(K_j, GL_n(\mathbb{C})) \) and by \( \mathcal{G} \) the group \( A^k(K_1 \cap K_2, GL_n(\mathbb{C})) \). Let \( \mu : \mathcal{G}_1 \times \mathcal{G}_2 \to \mathcal{G} \) be the map \( \mu(g_1, g_2) = g_2|_{K_1 \cap K_2} \cdot g_1|_{K_1 \cap K_2} \). Its derivative at the point \((1_{\mathcal{G}_1}, 1_{\mathcal{G}_2})\) is given by the linear map from the Banach space \( A^k(K_1, \text{Mat}_{n \times n}(\mathbb{C})) \oplus A^k(K_2, \text{Mat}_{n \times n}(\mathbb{C})) \) into the Banach space \( A^k(K_1 \cap K_2, \text{Mat}_{n \times n}(\mathbb{C})) \) given by \((h_1, h_2) \mapsto h_1|_{K_1 \cap K_2} + h_2|_{K_1 \cap K_2} \). Thanks to observation \ref{observation} above, this is surjective. Consequently, there is a neighborhood \( U \) of the identity in \( \mathcal{G} \) such that for any \( g \in U \) there are \( g_j \) in \( \mathcal{G}_j \) such that \( g = g_2 g_1 \) on \( K_1 \cap K_2 \). This proves the assertion when \( g \) is in the neighborhood \( U \). We may assume without any loss of generality that the exponential map is surjective diffeomorphism onto \( U \) from a neighborhood \( V \) of \( 0 \) in \( A^k(K_1 \cap K_2, \text{Mat}_{n \times n}(\mathbb{C})) \).

For the general case, observe that thanks to the fact that each component of \( K_1 \cap K_2 \) is contractible, the group \( \mathcal{G} \) is connected, and hence \( \mathcal{G} \) is generated by the neighborhood \( U \) of the identity. Therefore, we may write \( g = \prod_{i=1}^{N} \exp(h_i) \), where the \( h_i \in V \). Now, the set \( \mathbb{C} \setminus K_1 \cap K_2 \) is connected, and therefore it is possible to approximate each \( h_j \) by an entire matrix valued \( \tilde{h}_j \) such that on \( K_1 \cap K_2 \). Let \( \tilde{g} = \prod \tilde{h}_j \), and \( \tilde{g} = \tilde{g}^{-1} \cdot g \). If the approximation of \( h_j \) by \( \tilde{h}_j \) is close enough \( \tilde{g} \in U \),
and consequently it is possible to write $\hat{g} = a_2 a_1$, where $a_j \in \mathcal{G}_j$. We can take $g_1 = a_1$ and $g_2 = \hat{g} a_2$ to complete the proof. \hfill $\square$

The following solution of a non-linear Cousin problem is due to Rosay ([11], also see comments in [12]).

**Lemma 4.5.** Let $\omega$ be an open subset of $\mathbb{C}^n$ and let $F : \omega \to \mathbb{C}^n$ be a holomorphic immersion. Let $(K_1, K_2)$ denote a good pair of compact subsets of $\mathbb{C}$, and for some $k \geq 0$, let $u_1 \in \mathcal{A}^k(K_1, \mathbb{C}^n)$ be such that $u_1(K_1 \cap K_2) \subset \omega$. Given any $\epsilon > 0$, there exists $\delta > 0$ such that if $u_2 \in \mathcal{A}^k(K_2, \mathbb{C}^n)$ be such that $\|u_2 - F(u_1)\| < \delta$, then for $j = 1, 2$ there exist $v_j \in \mathcal{A}^k(K_j, \mathbb{C}^n)$ such that $\|v_j\| < \epsilon$, and $u_2 + v_2 = F(u_1 + v_1)$.

It is important to note that the map $u_1$ is fixed. In [12], a version is proved in which this restriction is removed. This requires a version of Cartan’s lemma for bounded matrices (see (2)), a result valid if $K_1$, $K_2$ and $K_1 \cup K_2$ are simply connected. Unfortunately, such a result could not be proved for the more general $K_1, K_2$ considered here. The proof will use the following well-known fact from the theory of Banach spaces, which can be proved using a standard iteration argument (see [3], pp. 397-98):

**Lemma 4.6.** Let $\mathcal{E}$ and $\mathcal{F}$ be Banach Spaces and let $\Phi : B_{\mathcal{E}}(p, r) \to \mathcal{F}$ be a $C^1$ map. Suppose there is a constant $C > 0$ such that:

- for each $h \in B_{\mathcal{E}}(p, r)$, the linear operator $\Phi'(h) : \mathcal{E} \to \mathcal{F}$ is surjective and the equation $\Phi'(h)u = g$ can be solved for $u$ in $\mathcal{E}$ for all $g$ in $\mathcal{F}$ with the estimate $\|u\|_{\mathcal{E}} \leq C \|g\|_{\mathcal{F}}$.
- for any $h_1$ and $h_2$ in $B_{\mathcal{E}}(p, r)$ we have $\|\Phi'(h_1) - \Phi'(h_2)\| \leq \frac{1}{2C}$.

Then,

$$\Phi(B_{\mathcal{E}}(p, r)) \supset B_{\mathcal{F}}(\Phi(p), \frac{r}{2C}).$$

We now give a proof of Lemma 4.5

**Proof.** Denote by $\mathcal{E}$ the Banach space $\mathcal{A}^k(K_1, \mathbb{C}^n) \oplus \mathcal{A}^k(K_2, \mathbb{C}^n)$, which we endow with the norm $\|\cdot\|_{\mathcal{E}} := \max \left(\|\cdot\|_{\mathcal{A}^k(K_1, \mathbb{C}^n)}, \|\cdot\|_{\mathcal{A}^k(K_2, \mathbb{C}^n)}\right)$. Also, let the open subset $\mathcal{U}$ of $\mathcal{E}$ be given by $\{(w_1, w_2) : w_1(K_1 \cap K_2) \subset \omega\}$. Then $(u_1, w_2) \in \mathcal{U}$, for any $w_2 \in \mathcal{A}^k(K_2, \mathbb{C}^n)$. a Let $\mathcal{F}$ be the Banach space $\mathcal{A}^k(K_1 \cap K_2, \mathbb{C}^n)$. Consider the map $\Phi : \mathcal{U} \to \mathcal{F}$ given by $\Phi(w_1, w_2) := w_2|_{K_1 \cap K_2} - F \circ (w_1|_{K_1 \cap K_2})$. A computation shows that $\Phi'(w_1, w_2)$ is the linear map from $\mathcal{E}$ to $\mathcal{F}$ given by $(v_1, v_2) \mapsto v_2|_{K_1 \cap K_2} -...
\( F'(w_1|_{K_1 \cap K_2})(v_1|_{K_1 \cap K_2}) \). Observe that \( w_2 \) plays no role whatsoever in this expression, and therefore \( \Phi'(w_1, w_2) \in BL(\mathcal{E}, \mathcal{F}) \) is in fact a smooth function of \( w_1 \) alone, and we will henceforth denote it by \( \Phi'(w_1, *) \).

We construct a right inverse to \( \Phi'(u_1, * ) \). Let \( \gamma = F'(u_1)|_{K_1 \cap K_2} \). Then \( \gamma \in \mathcal{A}^k(K_1 \cap K_2, GL_n(\mathbb{C})) \), and thanks to Lemma 14 above, we may write \( \gamma = \gamma_1 \cdot \gamma_2 \), where \( \gamma_j \in \mathcal{A}^k(K_j, GL_n(\mathbb{C})) \). (We henceforth suppress the restriction signs.) For \( g \in \mathcal{F} \), let \( S(g) = (-\gamma_1^{-1}T_1(\gamma_2^{-1}g), \gamma_2T_2(\gamma_2^{-1}g)) \), where the \( T_j \) are as in equation 22 above. Then \( S \) is a bounded linear operator from \( \mathcal{F} \) to \( \mathcal{E} \), and a computation shows that \( \Phi'(u_1, *) \circ S(g) \) is the identity map on \( \mathcal{F} \). Choose \( \theta > 0 \) so small so that if \( w_1 \in \mathcal{F} \) is such that \( \| w_1 - u_1 \| < \theta \) then (a) the equation \( \Phi'(w_1, *)u = g \) can be solved with the estimate \( \| u \| \leq 2 \| S \| \| g \| \), and (b) \( \| \Phi'(w_1, *) - \Phi'(u_1, *) \|_{op} < \frac{1}{8\| S \|} \). (These follow from continuity and the fact that small perturbations of surjective linear operator are still surjective) Consequently, if \( \epsilon < \theta \) and \( u_2 \in \mathcal{A}^k(K_2, \mathbb{C}^n) \), for the ball \( B_\mathcal{E}((u_1, u_2), \epsilon) \) the hypothesis of Lemma 4.6 are verified with \( C = 2 \| S \| \).

We have therefore,

\[
\Phi(B_\mathcal{E}((u_1, u_2), \epsilon)) \supset B_\mathcal{F}\left( \Phi(u_1, u_2), \frac{\epsilon}{2C} \right) = B_\mathcal{F}\left( u_2 - F(u_1), \frac{\epsilon}{2C} \right).
\]

So, if \( \| u_2 - F(u_1) \| < \frac{\epsilon}{4C} \), we have \( 0 \in \Phi(B_\mathcal{E}((u_1, u_2), \epsilon)) \). This is exactly the conclusion required.

We will now prove Theorem 5.

**Proof.** We omit the restriction signs on maps for notational clarity. For \( j = 1, 2 \) let the coordinate neighborhoods \( V_j \) of \( \mathcal{M} \) be such that \( f(K_j) \subset V_j \). We begin by fixing biholomorphic maps \( F_j : V_j \rightarrow F_j(V_j) \subset \mathbb{C}^n \), and set \( F = F_2 \circ F_1^{-1} \). Then \( F \) is a biholomorphism from the open set \( \omega = F_1(V_1 \cap V_2) \) onto the open set \( F_2(V_2 \cap V_1) \). Moreover, a pair of maps \( w_1 \) and \( w_2 \) from \( K_1 \) and \( K_2 \) respectively “glue together” to form a map from \( K_1 \cup K_2 \) (i.e., there is a map \( h : K \rightarrow \mathcal{M} \) such that \( w_j = F_j \circ h \)), only if \( w_2 = F(w_1) \).

Let \( u_1 = F_1 \circ f \in \mathcal{A}^k(K_1, \mathbb{C}^n) \). Since \( V \cap K_1 = \emptyset \) by hypothesis, the pair of compact sets \( (K_1, K_2 \cup V) \) is good. Fix \( \epsilon_0 > 0 \) and let \( \delta_0 > 0 \) be the \( \delta \) corresponding to \( \epsilon = \epsilon_0 \) in Lemma 4.5 for the good pair \( (K_1, K_2 \cup V) \) and \( F, \omega, u_1 \) as defined above. Let \( u_2 \in \mathcal{A}^k(K_2 \cup V, \mathbb{C}^n) \) be a \( \mathcal{C}^k \) approximation to \( F_2 \circ (f|_{K_2}) \) such that \( u_2(K_2) \subset V_2 \), and \( \| u_2 - F(u_1) \| < \delta_0 \). (Such a \( u_2 \) exists by hypothesis).
Then, by Proposition 4.5, there is a $v_1 \in A^k(K_1, \mathbb{C}^n)$ and a $v_2 \in A^k(K_2 \cup V \mathbb{C}^n)$, such that $\|v_j\| < \epsilon_0$ and $u_2 + v_2 = F(u_1 + v_1)$. Hence the maps $u_1 + v_1$ and $u_2 + v_2$ glue together to form a map $f_{\epsilon_0}$ given by

$$f_{\epsilon_0} := \begin{cases} F_1^{-1}(u_1 + v_1) & \text{on } K_1 \\ F_2^{-1}(u_2 + v_2) & \text{on } K_2 \text{ and near } K_2 \cap V \end{cases}$$

Clearly, $f_{\epsilon_0}$ is in $A^k(K_1 \cup K_2, \mathcal{M})$, and extends to a holomorphic map near $K_2 \cap V$. Moreover, $\text{dist}_{\mathcal{C}^k}(f_{\epsilon_0}, f) = O(\epsilon_0)$. The result follows. □

4.2. Proof of theorems 3 and 4. Let $k \geq 0$, be an integer, and let the domain $\Omega$ be circular if $k = 0$, and $C^1$ if $k \geq 1$. We fix $f \in A^k(\Omega, \mathcal{M})$. We want to approximate $f$ in the $\mathcal{C}^k$ sense on $\Omega$.

The basic idea of this proof is to slice the $\Omega$ by a system of parallel lines. If the slices are narrow enough, we will show that thanks to the results of Section 3 the graph of $f$ over each slice is contained in a coordinate neighborhood of $\mathcal{M}$. We will further show that the slicing can be done in a way that the unions of alternate slices form a good pair. Consequently, we can use the results of §4.1 to prove the approximation results. We break the proof up into a sequence of lemmas.

**Lemma 4.7.** Denote by $F$ the map in $A^k(\overline{\Omega}, \mathbb{C} \times \mathcal{M})$ given by $F(z) = (z, f(z))$. For real $\xi$, let $L_\xi$ be the vertical straight line $\{z \in \mathbb{C} : \Re z = \xi\}$. Then,

- $F(L_\xi \cap \overline{\Omega})$ has a coordinate neighborhood in $\mathbb{C} \times \mathcal{M}$, and
- There is a nowhere dense $E \subset \mathbb{R}$ such that if $\xi \notin E$, the line $L_\xi$ meets $\partial \Omega$ transversely. If $k = 0$, the set $E$ can even be taken to be finite.

**Proof.** We first prove that $F(L_\xi \cap \overline{\Omega})$ has a coordinate neighborhood. Each connected component of $L_\xi \cap \overline{\Omega}$ is a point or a compact interval, and thanks to the injectivity of $F$, if we show that for each such component $I$, the set $F(I)$ has a coordinate neighborhood in $\mathbb{C} \times \mathcal{M}$, it will follow that $F(L_\xi \cap \overline{\Omega})$ has a coordinate neighborhood in $\mathbb{C} \times \mathcal{M}$. This is trivial if the component $I$ is a point. Therefore, let $I$ be a compact interval. We consider three cases:

**Case 1:** $k = 0$. In this case $\Omega$ is a circular domain, and hence for each $\xi$ the set $L_\xi \cap \partial \Omega$ and a fortiori $I \cap \partial \Omega$ is finite. Consider the arc $F|_I$ in $\mathbb{C} \times \mathcal{M}$. This arc is real analytic off the finite set of points $I \cap \partial \Omega$, and the projection $\phi : \mathbb{C} \times \mathcal{M} \to \mathbb{C}$ has the property that $\phi \circ (F|_I)$ is the inclusion map $I \hookrightarrow \mathbb{C}$. Consequently, $F|_I$ is a real analytic mildly singular arc in the sense of Definition 3.4, and hence thanks to
Theorem 2. \( F(I) \) has a coordinate neighborhood.

Case 2: \( k = 1 \). In this case, the arc \( F|_I \) is \( C^1 \). As in the last case, let \( \phi \) be the projection \( \phi : \mathbb{C} \times \mathcal{M} \to \mathbb{C} \), which has the property that \( \phi \circ (F|_I) \) is the inclusion map \( I \hookrightarrow \mathbb{C} \). Therefore, Proposition 3.3 applies, and \( F(I) \) has a coordinate neighborhood.

Case 3: \( k \geq 2 \). In this case \( F|_I \) is a \( C^k \) embedded arc with \( k \geq 2 \), and hence by Corollary 3.2 it has a coordinate neighborhood.

We now turn to the second conclusion. In the case \( k = 0 \), the domain \( \Omega \) is circular, hence \( \partial \Omega \) is a disjoint union of circles. \( L_\xi \) is not transverse to \( \partial \Omega \) iff it is tangent to some component circle of \( \partial \Omega \). So we can take \( E \) to be the finite set of \( \xi \)'s such that \( L_\xi \) is tangent to \( \partial \Omega \).

In the case \( k \geq 1 \), let \( \Gamma \) be a connected component of \( \partial \Omega \). We can parameterize \( \Gamma \) by a \( C^1 \) map \( \gamma = \gamma_1 + i\gamma_2 : S^1 \to \Gamma \subset \mathbb{C} \). The line \( L_\xi \) is not transverse to \( \Gamma \) iff \( \xi \) is a critical value of \( \gamma_2 : S^1 \to \mathbb{R} \). By Sard's theorem, the set \( E_\Gamma \) of critical values of \( \gamma_2 \) is of measure 0. Of course \( E \) is closed. We let \( E = \bigcup E_\Gamma \), with a union over the finitely many components \( \Gamma \) of \( \partial \Omega \). Then \( E \) is nowhere dense.

We make the following simple observation:

**Observation 4.8.** Let \( u \) and \( v \) be real valued \( C^1 \) functions defined on a neighborhood of 0 in \( \mathbb{R} \) such that for each \( x \), we have \( u(x) < 0 < v(x) \). Then there is an \( \eta > 0 \) such that for \( 0 < \theta \leq \eta \), the vertical strip

\[
S := \{(x,y) \in \mathbb{R}^2 : x \in [-\theta, \theta], u(x) \leq y \leq v(x)\}
\]

is star shaped with respect to the origin.

**Proof.** Clear. \[ \square \]

We will now decompose \( \overline{\Omega} \) into a good pair \( (K_1, K_2) \).

**Lemma 4.9.** Let \( F \) be as in Lemma 4.7. There is a good pair \( (K_1, K_2) \) such that \( K_1 \cup K_2 = \overline{\Omega} \), and each \( F(K_j) \) has a coordinate neighborhood \( V_j \) in \( \mathbb{C} \times \mathcal{M} \).

**Proof.** Thanks to Lemma 4.7, for each vertical line \( L \), the set \( F(L \cap \overline{\Omega}) \) has a coordinate neighborhood in \( \mathbb{C} \times \mathcal{M} \). By compactness we can find finitely many points

\[
x_0 < x_1 < \cdots < x_N,
\]
such that for \( j = 0, \ldots, N - 1 \) the set \( \{ F(z) : x_j \leq \Re z < x_{j+1}, z \in \overline{\Omega} \} \) has a coordinate neighborhood in \( \mathbb{C} \times \mathcal{M} \), and each component of \( \{ z \in \mathbb{C} : x_j \leq \Re z < x_{j+1}, z \in \overline{\Omega} \} \) is simply connected. We will impose the following condition on the points \( x_j \): for each \( j \), the vertical line \( \Re z = x_j \) meets \( \partial \Omega \) transversely at each point of intersection. Since the set \( E \) of \( \xi \)'s such that \( \Re z = \xi \) is not transverse \( \partial \Omega \) has been shown above to be closed and of measure 0, this can be easily done.

Therefore, \( \partial \Omega \) is a union of (an even number of ) graphs of \( C^1 \) functions in a neighborhood of each of the vertical lines \( \Re z = x_j \). Thanks to Observation 4.8 above, there is an \( \eta \) such that if \( \theta \leq \eta \), each component of the intersection of \( \overline{\Omega} \) with a vertical strip of width \( \theta \) about the line \( \Re z = x_j \) is star shaped. Define the compact subsets \( K_1 \) and \( K_2 \) of \( \mathbb{C} \) given by

\[
K_1 := \{ z \in \overline{\Omega} : x_{2j-1} - \theta \leq \Re z \leq x_{2j} + \theta, j = 1, 2, \ldots \}
\]

and

\[
K_2 := \{ z \in \overline{\Omega} : x_{2j} \leq \Re z \leq x_{2j+1}, j = 1, 2, \ldots \}.
\]

In other words, \( K_2 \) (resp. \( K_1 \)) consists of the slices of \( \overline{\Omega} \) over the odd numbered intervals in the partition \( x_0 < x_1 < \cdots < x_N \) (resp. the slices over the even numbered ones slightly enlarged). The sets \( \overline{K_1 \setminus K_2} \) and \( \overline{K_2 \setminus K_1} \) are disjoint, and each \( F(K_j) \) has a coordinate neighborhood in \( \mathbb{C} \times \mathcal{M} \), which will be our \( V_j \).

We can now use Theorem 5 to prove the following approximation result:

**Proposition 4.10.** There is a point \( p \in \partial \Omega \) with the following property: given any \( \epsilon > 0 \), there is a neighborhood \( U_\epsilon \) of \( p \) in \( \mathbb{C} \) and a map \( g \in A^k(\overline{\Omega}, \mathcal{M}) \), such that \( \text{dist}_{C^k(\overline{\Omega}, \mathcal{M})}(f, g) < \epsilon \), and \( g \) extends as a holomorphic map to \( U_\epsilon \).

**Proof.** The proof is an application of Theorem 5. Let as before, \( F(z) = (z, f(z)) \). In the notation of that lemma we choose the following data:

- the good pair \( (K_1, K_2) \) will be the one in the conclusion of Lemma 4.9 so that \( K_1 \cup K_2 = \Omega \), and each of \( F(K_1) \) and \( F(K_2) \) has a coordinate neighborhood in \( \mathbb{C} \times \mathcal{M} \).
- Let \( p \in (K_2 \setminus K_1) \cap \partial \Omega \), and let \( V \) be a closed disc around \( p \) such that \( V \cap K_1 = \emptyset \). It is clear (e.g. by an easily established \( C^k \) version of Mergelyan’s theorem) that any function in \( A^k(K_2) \) can be approximated in the \( C^k \) sense by entire functions, therefore a fortiori by functions in \( A^k(K_2 \cup V) \).
• We will let the target manifold be $\mathbb{C} \times \mathcal{M}$ (denoted by $\mathcal{M}$ in the statement of lemma 5), and the map to be approximated be $F$. As remarked above, $F(K_j)$ has a coordinate neighborhood in $\mathbb{C} \times \mathcal{M}$.

Therefore, by Lemma 5 we obtain a $C^k$ approximation $G$ to $F$ on $K_1 \cup K_2 = \Omega$, where $G$ extends holomorphically to some neighborhood $U_\epsilon$ of $p$, and we have $\text{dist}_{C^k(\mathcal{M})} (F, G) < \epsilon$. Let $g = \pi \circ G$, where $\pi : \mathbb{C} \times \mathcal{M} \to \mathcal{M}$ is the projection onto the second component.

At this point, the approximation has been achieved in a neighborhood of one point $p$ in the boundary. We could repeat this process, thus obtaining a proof of Theorems 3 and 4. This would require a strengthened version of Proposition 4.10 in which (i) we can choose the point $p$ arbitrarily, and (ii) the diameter of the set $\partial \Omega \cap U_\epsilon$ is independent of $p$. This is the route followed in [3].

In this paper however, we complete the proof using a technique found in [5], which in the setting of our problem allows us to avoid entirely the method of successive bumpings outlined above. We explain this method in the following lemma.

**Lemma 4.11.** Let $D$ be a $C^1$ domain in the plane, and let $V$ be an open set in $\mathbb{C}$ such that $\partial D \cap V \neq \emptyset$. Then there is a one parameter family $\psi_t \in \mathcal{H}(\overline{D})$, such that for small $t \geq 0$, we have $\psi_t(\overline{D}) \subset D \cup V$, and as $t \to 0$, $\psi_t \to \psi_0$ in the $C^\infty$ sense, where $\psi_0$ is the identity map $\psi_0(z) = z$.

**Proof.** The case in which $\partial D$ is connected being trivial, we assume that it has at least two components. For a Jordan curve $C \subset \mathbb{C}$, denote by $\beta(C)$ the bounded component of $\mathbb{C} \setminus C$. Let $\{C_k\}_{k=1}^{M+1}$ be the components of $\partial D$, where $V \cap C_{M+1} \neq \emptyset$. There is a component $C_j$ of $\partial D$ with the following properties: for $k \neq j$, we have (i) $C_k \subset \beta(C_j)$ and (ii) $\beta(C_k) \cap D = \emptyset$. Call $C_j$ the outer boundary of $D$.

Without loss of generality we may assume that the outer boundary of $D$ is $C_{M+1}$. If this is not already the case, make in a neighborhood of $\overline{D}$ the change of coordinates $z \mapsto \frac{z^2}{z-z_0}$, where $z_0 \in \beta(C_{M+1})$, and $\rho > 0$ is so small that $B_{\mathbb{C}}(z_0, \rho) \Subset \beta(C_{M+1})$.

Let $V_0 \Subset V$ be such that $V_0 \cap C_{M+1} \neq \emptyset$, and for $1 \leq k \leq M$, we have $V_0 \cap C_k = \emptyset$. Let $\Gamma = \partial D \setminus V_0$. Then $\mathbb{C} \setminus \Gamma$ has $M+1$ components. Exactly one of these is unbounded, and this component contains the set $C_{M+1} \setminus V_0$. Let $P$ be a set of $M$ points, such that for $j = 1, \ldots, M$, each bounded component $\beta(C_j)$ of $\mathbb{C} \setminus \Gamma$ contains exactly one point of $P$. Of course, $P \cap D = \emptyset$. 
Let $N$ be the inward directed unit normal vector field on $\partial D$. Identifying $T\mathbb{C}$ with $\mathbb{C}$, the restriction $N|_\Gamma$ is a continuous function on the set $\Gamma$. Since $\Gamma$ has no interior, and $\mathbb{C}\setminus \Gamma$ has finitely many components, $N$ can be uniformly approximated on $\Gamma$ by rational functions holomorphic on $\mathbb{C}\setminus P$. We therefore obtain a holomorphic vector field $X$ on $\overline{D}$ such that $X|_\Gamma$ is directed inward, i.e., towards $D$. Denote by $\psi_t$ the holomorphic flow generated by $X$. Clearly, on any compact set, $\psi_t$ approaches the identity in all $C^k$ norms as $t \to 0$. For small $t \geq 0$, we have $\psi_t(\Gamma) \subset D$, and by continuity, $\psi_t(\partial D \cap \overline{V_0}) \subset V$. Therefore, $\psi_t(\partial D) \subset D \cup V$, so that $\psi_t(\overline{D}) \subset D \cup V$. □

We can now end the proof of Theorems 3 and 4. Suppose that $\epsilon > 0$ is given, and we want to find a $h \in A^k(\overline{\Omega}, \mathcal{M})$ such that $\text{dist}_{C^k(\overline{\Omega}, \mathcal{M})}(f, h) < \epsilon$. Using Lemma 4.10 above, we can construct an approximation $g$ which extends holomorphically to a neighborhood $U_\epsilon$ of a point $p$ on the boundary, and we have $\text{dist}_{C^k(\overline{\Omega}, \mathcal{M})}(f, g) < \frac{\epsilon}{2}$. In lemma 4.11 let $V = U_\epsilon$, and $D = \Omega$. Let $\psi_t$ be the family of biholomorphisms in the conclusion of Lemma 4.11. Then, $g_t = g \circ \psi_t$ is in $H(\overline{\Omega}, \mathcal{M})$ for small $t$, and as $t \to 0$, we have $g_t \to g$ in the $C^k$ sense on $\overline{\Omega}$. Therefore, taking $t > 0$ small enough we obtain $h = g_t$ such that $\text{dist}_{C^k(\overline{\Omega}, \mathcal{M})}(h, g) < \frac{\epsilon}{2}$. Theorems 3 (and therefore Theorem 3) are therefore proved.
