(Dated: June 4, 2012)

Cosmological data have provided new constraints on the number of neutrino species and the neutrino mass. However these constraints depend on assumptions related to the underlying cosmology. Since a correlation is expected between the number of effective neutrinos \(N_{\text{ eff}}\) and the curvature \(\Omega_k\), it is useful to investigate the current constraints in the framework of a non-flat universe. In this paper we update the constraints on neutrino parameters by making use of the latest cosmic microwave background (CMB) data from the ACT and SPT experiments and consider the possibility of a universe with non-zero curvature. We first place new constraints on \(N_{\text{ eff}}\) and \(\Omega_k\), with \(N_{\text{ eff}} = 4.03 \pm 0.45\) and \(10^3 \Omega_k = -4.46 \pm 5.24\). Thus, even when \(\Omega_k\) is allowed to vary, \(N_{\text{ eff}} = 3\) is still disfavored with 95% confidence. We then investigate the correlation between neutrino mass and curvature that shifts the 95% upper limit of \(\sum m_\nu < 0.45\) eV to \(\sum m_\nu < 0.95\) eV. Thus, the impact of assuming flatness in neutrino cosmology is significant and an essential consideration with future experiments.

I. INTRODUCTION

Throughout the previous decades experimental cosmology has benefited from accurate measurements of the cosmic microwave background (CMB). The data have determined constraints on several cosmological parameters to remarkable accuracy and the ability to constrain new physics with the CMB continues to improve. Future CMB experiments might even be able to measure B-mode polarization and distinguish between neutrino hierarchy and non-instantaneous decoupling of neutrinos) \[6, 7\].

Here we present an update on the constraints of the number of neutrino species \(N_{\text{ eff}}\) and the sum of neutrino masses \(\sum m_\nu\) in the framework of non-flat universes with \(\Omega_k \neq 0\) combining the Wilkinson Microwave Anisotropy Probe (WMAP) 7-year \[3\], South Pole Telescope (SPT) \[4\] and Atacama Cosmology Telescope (ACT) \[5\] datasets.

The paper is organized as follows. In Section II we give theoretical arguments for why the \(N_{\text{ eff}}\) and \(\Omega_k\) parameters should be correlated. In Section III we discuss our method of constraining the parameters \(N_{\text{ eff}}, \sum m_\nu, \text{ and } \Omega_k\). We present the results of the analysis in Section IV. Finally, in Section V we conclude and discuss the implications of assuming flatness in neutrino cosmology.

II. THE EFFECTIVE NEUTRINO NUMBER

The effective neutrino number \(N_{\text{ eff}}\) is defined as the contribution of neutrinos to the relativistic degrees of freedom \(g_*\). In a standard physics scenario the particles contributing to the total value of \(g_* \simeq 10.75\) are electrons, three neutrinos (and their antiparticles), and photons. Any extra relativistic degrees of freedom can be parameterized in terms of an excess with respect to the standard effective neutrino number \(N_{\text{ eff}} = 3\) (which more precisely is \(\simeq 3.046\) after accounting for QED corrections and non-instantaneous decoupling of neutrinos) \[6, 7\].

The neutrino energy density is:

\[
\rho_\nu = N_{\text{ eff}} \frac{7}{8} \left( \frac{4}{11} \right)^{4/3} \rho_\gamma ,
\]

where \(\rho_\gamma\) is the energy density of photons. A first effect of \(N_{\text{ eff}}\) is related to the primordial helium abundance \(Y_p\). Changing \(N_{\text{ eff}}\) affects the freeze-out temperature \(T_{\text{ freeze}}\) during BBN and therefore the final neutron to proton ratio \(n_n/n_p\) \[8\]. Larger \(N_{\text{ eff}}\) means earlier freeze-out, larger \(n_n/n_p\), and larger \(Y_p\).

The effect of \(N_{\text{ eff}}\) on cosmological observables (e.g. CMB anisotropy power spectrum and galaxy power spectrum) is emphasized by the epoch of matter-radiation equality \(a_{eq}\). In particular, for what concern the CMB, an increase in \(a_{eq}\) changes the extent of the early Integrated Sachs-Wolfe effect. The relation between \(a_{eq}\) and \(N_{\text{ eff}}\) is given by equating energy densities:

\[
\rho_{\text{rad}} = \rho_m \iff a_{eq} = \frac{1 \pm 0.227 N_{\text{ eff}}}{40484 \Omega_m h^2} .
\]

This shows a linear relationship for \(a_{eq}(N_{\text{ eff}})\), which
transfers to the baryon to photon ratio at equality [9]:

\[ R_{eq} = \frac{3\rho_b}{4\rho_\gamma} \bigg|_{a_{eq}}, \]

\[ = 30496 \Omega_b h^2 a \bigg|_{a_{eq}}, \]

\[ = \frac{1 + 0.227N_{eff} \Omega_b}{1.3276} \Omega_m. \] (3)

The presence of baryons in the relativistic cosmic fluid slows down the sound speed according to the definition,

\[ c_s = 1/\sqrt{3(1+R)}, \] (4)

and so this quantity is also affected at equality by the effective neutrino number. This reflects in the size of sound horizon at a generic time \( \tau \) [9]:

\[ r_s = \int_0^\tau d\tau' c_s(\tau'), \]

\[ = \int_0^a \frac{da}{a^2 H} c_s(a), \]

\[ \approx \frac{2}{3k_{eq}} \sqrt{\frac{6}{R_{eq}}} \ln \left\{ \frac{\sqrt{1+R} + \sqrt{R+R_{eq}}}{1 + \sqrt{R_{eq}}} \right\}, \]

\[ = \frac{6.612 \times 10^{-3}}{H_0 \sqrt{\Omega_m \Omega_b h^2}} \ln \left\{ \frac{\sqrt{1+R} + \sqrt{R+R_{eq}}}{1 + \sqrt{R_{eq}}} \right\}. \] (5)

The last equations come from assuming the Universe is matter dominated during recombination. As can be seen, the sound horizon depends on \( N_{eff} \) through \( R_{eq} \).

![Graph showing \( r_s/D_A \) vs. \( z \) for different \( N_{eff} \) values.]

\[ \theta_s = r_s / D_A \]

FIG. 1. A demonstration of how the sound horizon \( r_s \) changes with the effective neutrino number \( N_{eff} \) under the matter dominated approximation given by Eq. 5.

In recent papers (see e.g. [10–12]) it has been found that the number of neutrinos is greater than the standard model value at more than 2\( \sigma \). The presence of additional neutrinos can be described by a (3+1) or (3+2) model with three active neutrinos and one or two sterile neutrinos [13–14]. More exotic solutions may include arguments supporting modified dark energy models [15–17]. In this work we explore possible overlooked parameter degeneracies that could still favor the standard model without the introduction of new physics.

In [10] the authors provide qualitative arguments for how changing the number of allowed neutrinos affects the observed values of parameters. One example which we use is the relative dependence of distance measurements on the Hubble constant. In fact, the sound horizon at recombination scales as \( r_s \propto 1/H \) while the distance a photon typically diffuses prior to its last scattering goes as \( r_s \propto 1/\sqrt{H} \). This is significant because the response of the radiation relative to matter determines the degree of damping prior to recombination. In other words, with \( \theta_s = r_s/D_A \) fixed by observation, the angular diameter distance, \( D_A \), must also decrease as \( 1/H \) which is more rapid than \( r_s \). Thus, the damping increases according to \( \theta_d = r_d/D_A \propto \sqrt{H} \) [10]. If these distances vary according to \( H \) then they also vary according to any parameter correlated with \( H \). In an open universe with nonzero curvature the effective neutrino number is slightly reduced. The theory confirms this because as stated above \( \theta_s \) is constrained by observation which means if \( N_{eff} \) is reduced and \( \Omega_k > 0 \) then \( r_s \) and \( D_A \) both increase (see Fig. 1). However, if the parameter space favors a closed universe then there will appear to be a higher number of effective neutrinos. This is one of the primary reasons for expecting correlation between \( N_{eff} \) and \( \Omega_k \).

We conclude this section by stating our purpose further constrain the neutrino mass and investigate the effect of curvature on this parameter. Finally, we acknowledge that there are many papers on the subject of constraining neutrino parameters. A non-exhaustive list of additional references includes Refs. [18–31].

III. ANALYSIS METHOD

In order to fit cosmological models to data we use a modified version of the publicly available CosmoMC software package [32]. This uses a Monte Carlo Markov Chain analysis on calculations of the lensed CMB power spectrum made with the CAMB package. Our analysis combines the following CMB anisotropy datasets: WMAP 7-year [3], SPT [4], and ACT [5]. Including BAO+H0 simply means we are using the baryon acoustic oscillation (BAO) data of Percival et al. [33] and impose a prior on the Hubble parameter based on the last Hubble Space Telescope observations [34]. We integrate spectral data out to \( \ell_{max} = 3000 \). We sample from the following parameters: the baryon \( \Omega_b h^2 \), cold dark matter \( \Omega_c h^2 \), and dark \( \Omega_x \) energy densities, the scalar spectral index \( n_s \), the optical depth to reionization \( \tau \), the Hubble parameter \( H_0 \), and the amplitude of SZ spectrum \( A_{SZ} \). We also consider the effective neutrino number \( N_{eff} \), spatial curvature \( \Omega_k \), and the sum of neutrino masses \( \sum m_{\nu} \).

Finally, we make decisions specific to the high multipole mode data. We consider purely adiabatic initial con-
ditions. When the background data are taken to small enough scales the spectra from infrared source emission must be taken into account. The IR spectra is dominated by Poisson power partially from source emission clustering at the smallest scales. Thus, a model for such effects must be subtracted out from the CMB power spectra. The resulting adaptations are representative of the effects must be subtracted out from the CMB power spectrum. Fig. 2 demonstrates the correlation between Ω_k and N_{eff}. The credible intervals are given at the 68% and 95% confidence levels and the markers indicate the locations of the marginalized values. WMAP+BAO+H_0 is shown in red while WMAP+ACT+SPT+BAO+H_0 is in blue. Note that the effect of adding additional datasets is significant.

IV. RESULTS

Under the flat Universe scenario the constraint improves to N_{eff} = 3.89 ± 0.41 at the 68% confidence level (see Table I). This result suggests N_{eff} = 3 is inconsistent with the data with ~95% confidence.

We then allow the curvature to vary, to determine how assuming flatness affects the constraints on N_{eff}. Fig. 2 demonstrates the correlation between Ω_k and N_{eff}, which agrees with the prediction from Section II. Interestingly, the effect of the additional CMB datasets (ACT and SPT) increases the correlation between these parameters with respect to WMAP 7-year data alone. This may be due in part to the considerable improvement in N_{eff} whereas the uncertainty in the curvature is not noticeably improved by the addition of small scale anisotropy measurements. These results suggest that an open universe with fewer neutrinos would look similar to a flat universe with more neutrinos. We also note that when including N_{eff} as a free parameter in the ΛCDM+Ω_k model, the 1σ constraint of Ω_k = −0.0023+0.0054−0.0056 found in Ref. 3 does not deteriorate significantly for the same combination of datasets (i.e. WMAP+BAO+H_0). This is due to the presence of the BAO data and the H_0 prior in the analysis, since both probes are sensitive to the geometry of the Universe. Therefore, BAO and H_0 help to break the degeneracy between N_{eff} and Ω_k.

Table I provides a summary of parameter values for runs where Ω_k and N_{eff} vary. Here we find N_{eff} = 4.03 ± 0.45 and 10^3Ω_k = −4.46 ± 5.24 at the 68% confidence level. Therefore, even when Ω_k is allowed to vary, N_{eff} = 3 is still disfavored with ~95% confidence. Note that the increased value for H_0 is indicative of the known correlation between H_0 and Ω_k. We provide an equiva-

| Parameter | WMAP7+BAO+H_0 | WMAP7+SPT | WMAP7+ACT | WMAP7+SPT+ACT |
|-----------|---------------|-----------|-----------|---------------|
| 100Ω_bh^2 | 2.249 ± 0.054 | 2.256 ± 0.041 | 2.235 ± 0.047 | 2.258 ± 0.040 |
| Ω_c h^2   | 0.135 ± 0.016 | 0.130 ± 0.0094 | 0.137 ± 0.012 | 0.129 ± 0.0091 |
| Ω_Λ       | 0.721 ± 0.018 | 0.722 ± 0.015 | 0.714 ± 0.018 | 0.722 ± 0.015 |
| n_s       | 0.979 ± 0.015 | 0.980 ± 0.0122 | 0.982 ± 0.013 | 0.9803 ± 0.0121 |
| τ         | 0.086 ± 0.014 | 0.085 ± 0.014 | 0.086 ± 0.014 | 0.086 ± 0.014 |
| H_0 (km/s/Mpc) | 75.1 ± 3.4 | 74.0 ± 2.0 | 74.6 ± 2.15 | 73.9 ± 1.92 |
| N_{eff}   | 4.34 ± 0.88  | 3.91 ± 0.43  | 4.30 ± 0.58  | 3.89 ± 0.41  |

TABLE I. Summary of matching results from WMAP 7-year [3], SPT [4], and ACT [5]. Note that the analyses are modeled by the choice to reproduce SPT results, which produces a smaller value for N_{eff} than expected for ACT data. All datasets include BAO and H_0 for improved parameter constraints. The quoted errors are given at the 68% confidence levels (CL).
lent marginalized contour plot of $H_0$ vs. $N_{\text{eff}}$ to emphasize the connection (see Fig. 3).

We now turn to the question of how well the datasets are able to constrain $\sum m_\nu$. Table III shows the results from WMAP in the first column and the result of adding the additional datasets in the final column. Although the constraint greatly improves the two sigma limit for the masses, this is not enough to favor either the standard or inverted hierarchy. However, this is not a surprise because none of the datasets are sensitive enough on their own. Forthcoming data from the Planck experiment and other future experiments will likely improve the mass constraint [37].

Finally, we investigate the effect of assuming flatness while determining an upper bound on $\sum m_\nu$. We investigate two models. The first assumes three degenerate massive neutrinos, while the second allows for additional relativistic species accounted by $\Delta N_{\text{eff}} > 0$. We define the correlation coefficient $\rho_{ij}$ as the ratio of the off-diagonal term of the covariance matrix $\sigma_{ij}$ to the 1σ errors $\sigma_i \sigma_j$, so that for two parameters denoted by i and j we have $\rho_{ij} = \sigma_{ij}/\sigma_i \sigma_j$. Figure 4 shows that $\sum m_\nu$ and $\Omega_k$ are strongly correlated with a correlation coefficient of $\rho_{\Omega_k \sum m_\nu} = 0.78$ for both models ($\Delta N_{\text{eff}} = 0$ and $\Delta N_{\text{eff}} > 0$). Furthermore, the degeneracy considerably increases the uncertainty in the sum of the neutrino masses. In fact, with $\Omega_k \neq 0$ the 95% upper limit on $\sum m_\nu$ more than doubles with respect to the flat case: with $\sum m_\nu < 0.95$ eV for the model assuming only three massive neutrinos and $\sum m_\nu < 1.19$ eV for $\Delta N_{\text{eff}} > 0$. The strong correlation between curvature and mass is expected because massive neutrinos with $m_\nu < 0.3$ eV are still relativistic until recombination so they act as an additional radiative component. As a consequence the presence of such massive neutrinos shifts the time of matter-radiation equality $a_{\text{eq}}$. Recall the discussion in Section II where in this case lower mass neutrinos roughly correspond to higher $N_{\text{eff}}$. Neutrinos also leave an imprint on the CMB through the early Integrated Sachs-Wolfe effect (c.f. Refs. [38, 39]) which changes the position of acoustic peaks. This effect can be compensated for by a change in the geometry of the Universe, which weakens the constraints on both $\sum m_\nu$ and $\Omega_k$. See Table IV for a summary of cosmological parameters when curvature and massive neutrinos are considered.

### V. CONCLUSION

The resolution of the high effective neutrino number in cosmology remains an open question. However, additional neutrinos may be due to parameter degeneracy or other issues in statistical analysis rather than new physics. The focus of this paper has been an argument for correlation between the number of effective neutrinos $N_{\text{eff}}$ and the curvature of the Universe $\Omega_k$, which arises from the effect of these parameters on distance measurements. The qualitative argument is confirmed by a statistical analysis of CMB anisotropy measurements using CosmoMC.

In this paper we have shown that there is a correlation

| Parameter | WMAP7$+N_{\text{eff}}+\Omega_k$ | ...$+\text{ACT}+\text{SPT}$ |
|-----------|---------------------------------|-----------------------------|
| $100\Omega_k h^2$ | $2.26 \pm 0.053$ | $2.23 \pm 0.038$ |
| $\Omega_k h^2$ | $0.112 \pm 0.0036$ | $0.111 \pm 0.0029$ |
| $\Omega_\Lambda$ | $0.719 \pm 0.0182$ | $0.726 \pm 0.0154$ |

| $H_0$ (km/s/Mpc) | $70.6 \pm 1.62$ | $73.1 \pm 2.03$ |
| $10^3 \Omega_b$ | $7.52 \pm 7.74$ | $3.46 \pm 8.69$ |
| $\sum m_\nu$ | $< 0.95$ eV | $< 1.19$ eV |
| $\Delta N_{\text{eff}}$ | 0 | $0.995 \pm 0.430$ |

TABLE IV. Summary of the constraint on the sum of the neutrino masses when $\Omega_k \neq 0$. $\Delta N_{\text{eff}}$ is an additional relativistic contribution after considering 3.046 massive neutrinos. Datasets include WMAP7+ACT+SPT+BAO+$H_0$. Errors are at the 68% CL except for $\sum m_\nu$, which is quoted as a 95% upper limit.

Future experiments will provide further insight into both $N_{\text{eff}}$ and $\sum m_\nu$. Our results are consistent with the current understanding of the data available. The strongest constraints on these parameters from the statistical analysis assuming a flat universe are $N_{\text{eff}} = 3.89 \pm 0.41$ and $\sum m_\nu < 0.45$ eV with 95% confidence level using WMAP7+ACT+SPT+BAO+$H_0$. The constraints are weakened by degeneracy with the curvature parameter $\Omega_k$. However, this still represents the continued effort toward significant improvements on parameter constraints in cosmology. Although the sum of the neutrino masses is significantly improved from the WMAP 7-year result of $\sum m_\nu < 0.57$ eV, the constraint is far from being sensitive enough to rule out one of the mass hierarchies. Furthermore, we have shown that the mass uncertainty more than doubles when $\Omega_k \neq 0$. Based on our results and the estimated quality of data for Planck and other experiments, it should be possible to determine the existence or nonexistence of sterile radiation to much greater confidence in the near future.
