Abstract

In this paper we study the Casimir energy of a sample made by $N$ cavities, with $N \gg 1$, across the transition from the metallic to the superconducting phase of the constituting plates. After having characterised the energy for the configuration in which the layers constituting the cavities are made by dielectric and for the configuration in which the layers are made by plasma sheets, we concentrate our analysis on the latter. It represents the final step towards the macroscopical characterisation of a “multi cavity” (with $N$ large) necessary to fully understand the behaviour of the Casimir energy of a YBCO (or a BSCCO) sample across the transition.

Our analysis is especially useful to the Archimedes experiment, aimed at measuring the interaction of the electromagnetic vacuum energy with a gravitational field. To this purpose, we aim at modulating the Casimir energy of a layered structure, the multi cavity, by inducing a transition from the metallic to the superconducting phase. After having characterised the Casimir energy of such a structure for both the metallic and the superconducting phase, we give an estimate of the modulation of the energy across the transition.

1. INTRODUCTION

The principal goal of the Archimedes experiment \[1\] is to measure the coupling of the vacuum fluctuations of Quantum Electrodynamics (QED) to the gravitational field of the Earth. The coupling is obtained, as usual in Quantum Field Theory in Curved spacetime \[2–5\], assuming the Einstein tensor to be proportional to the expectation value of the regularized and renormalized energy-momentum tensor of matter fields, in particular, for the Archimedes experiment, of the electromagnetic field. The idea is to weigh the vacuum energy stored in a rigid Casimir cavity \[6\], made by parallel conducting plates, by modulating the reflectivity of the plates upon inducing a transition from the metallic to the superconducting state \[1\]. The “modulation factor” is defined as \[\eta = \frac{\Delta E}{E}\] were \[\Delta E\] is the difference of Casimir energy in the normal and in the superconducting state.

In Ref. \[1\] it was shown that, in order to measure such an effect, \[\eta\] must be of the order \[\eta \sim 10^{-5}\] and that, to this purpose, a multi cavity, obtained by superimposing many cavities must be used. This structure is natural in the case of crystals of type-II superconductors, particularly cuprates, being composed by Cu-O planes, that undergo the superconducting transition, separated by nonconducting planes. A crucial aspect to be tested is the behavior of the Casimir energy \[6\] for a multi cavity when the layers undergo the phase transition from the metallic to the superconducting phase. In a previous paper \[7\] a careful study for such a type of structure has been carried out for a sample made by up to three “relatively thick” (of the order of ten nanometer) dielectric layers. In the present paper we extend the analysis to any number of cavities for both situations: layers consisting of “thick” dielectric slabs and layers consisting of “thin” plasma sheets.

Indeed, in Ref. \[8\], considering a cavity based on a high-\[T_c\] layered superconductor, a factor as high as \[\eta = 4 \times 10^{-4}\] has been estimated (for flat plasma sheets at zero temperature and no conduction in the normal state, so that \[\Delta E\] corresponds to the energy of the ideal cavity, and charge density \[n = 10^{14}\text{ cm}^{-2}\]). The Archimedes sensitivity is expected to be capable of assessing the interaction of gravity and vacuum energy also for values lower than \[\eta = 4 \times 10^{-4}\], up to 1/100 of this value \[1\]. It is then crucial to understand the level of modulation achievable with layered superconducting structures. This is the scope of the present paper.

Considering in particular the multi cavity, the general assumption adopted so far has been that the Casimir energy obtained by overlapping many cavities is the sum of the energies of each individual cavity. This is true if the distances between neighboring cavities are large (in the sense that the thickness of each metallic layer separating the various cavities is very large with respect to the penetration depth of the radiation field). Of course, this is no longer true if the thickness of these metallic inter-cavity layers gets thinner and thinner.

Sec. II studies the Casimir energy of a multilayered cavity, assuming either dielectric or plasma sheet matching conditions at each interface between the layers. In Sec. III, numerical calculations are carried out and an analytic model capable of describing the Casimir energy at finite temperature is given. Finally, in Sec. IV, a possible model for describing the variation (and the modulation) of the Casimir energy across the transition is introduced. Our concluding remarks are found in Sec. V.
2. THE CASIMIR ENERGY OF $N$ COUPLED CAVITIES

In this section we deduce the Casimir Energy of $N$ coupled cavities, even though in the present paper we are interested in applying our results to plasma sheets, we will discuss the case of dielectrics first and then recover the plasma sheets results as a suitable limiting case.

In the following, referring to Fig. 1, $d_i$ is the distance of the $i$-th cavity from the $(i-1)$-th, (thickness of the $i$-th cavity), within the slabs 1, 3 and 5 there is vacuum while the regions 0, 2, 4 and 6 are dielectric. The thickness of the regions 0 and 6 is assumed to be infinite.

![Fig. 1: A $N$ layer cavity. For the dielectric case in the 0, 2, 4, ..., and all even-numbered regions there is a dielectric and in the 1, 3, 5, ..., and all odd-numbered regions there is vacuum. $d_i$ is the thickness of the $i$-th slab. In the case of plasma-sheet there is vacuum everywhere and the layer are simple interfaces (of zero thickness) at $z = d_1, d_2, ...$](image)

The general expression for the Casimir energy (per unit area), at finite temperature, will be written in the usual manner [9-11]

$$E = k_B T \sum_{l=0}^{\infty} \int \frac{d\kappa}{(2\pi)^2} \left[ \log \Delta^{TE}(\zeta_l) + \log \Delta^{TM}(\zeta_l) \right]$$

(1)

where the $\Delta$ are the so called generating functions (in the following we will omit the subscript TM(TE) if no ambiguity is generated), $\zeta_l = 2\pi l k_B T$ are the Matsubara frequencies, $k_B$ is the Boltzmann constant, $l = 0, 1, 2, \ldots$, and the superscript $'$ on the sum means that the zero mode must be multiplied by a factor $\frac{1}{2}$. The generating functions are obtained by computing the determinant of the most general boundary conditions at each singular layer located at $d_0, d_0 + d_1, d_0 + d_1 + d_2$ etc. (see Fig. 1 see also the appendix) [12].
For the sake of clarity, we only give here the general argument about the procedure for obtaining the generating functions, referring the reader to the appendix for the complete computation. In the appendix we show that the $\Delta$ functions can be written in terms of a sort of generalised reflection coefficients:

$$R_{TM}^{i,j} = \frac{\epsilon_j(i\gamma_l)K_i - \epsilon_i(i\gamma_l)K_j - 2\Omega\epsilon_{ij}K_iK_j}{\epsilon_j(i\gamma_l)K_i + \epsilon_i(i\gamma_l)K_j + 2\Omega\epsilon_{ij}K_iK_j},$$

$$S_{TM}^{i,j} = \frac{\epsilon_j(i\gamma_l)K_i - \epsilon_i(i\gamma_l)K_j + 2\Omega\epsilon_{ij}K_iK_j}{\epsilon_j(i\gamma_l)K_i + \epsilon_i(i\gamma_l)K_j + 2\Omega\epsilon_{ij}K_iK_j},$$

$$T_{TM}^{i,j} = \frac{\epsilon_j(i\gamma_l)K_i + \epsilon_i(i\gamma_l)K_j - 2\Omega\epsilon_{ij}K_iK_j}{\epsilon_j(i\gamma_l)K_i + \epsilon_i(i\gamma_l)K_j + 2\Omega\epsilon_{ij}K_iK_j},$$

$$R_{TE}^{i,j} = \frac{K_i - K_j + 2\Omega}{K_i + K_j + 2\Omega},$$

$$S_{TE}^{i,j} = \frac{K_i - K_j - 2\Omega}{K_i + K_j + 2\Omega},$$

$$T_{TE}^{i,j} = \frac{K_i + K_j - 2\Omega}{K_i + K_j + 2\Omega},$$

where $K_i = \sqrt{k_i^2 + \epsilon_i(i\gamma_l)c_0^2}$, $k_i = (k_x, k_y)$, $\Omega = \frac{\mu_{0\text{rad}}q^2}{m^*}$, $\mu_0$ is the magnetic permeability of vacuum, $n_{2D}$ is the two dimensional carrier density in the layer, and $q^*$ and $m^*$, respectively, their charge and mass. The standard dielectric boundary conditions (dbc) will be recovered by imposing $\Omega = 0$ and the plasma sheet boundary conditions (psbc) by requiring $\epsilon_i(i\gamma_l) = 1$, $\forall i$ (in this case, $K_i = K_j$).

After introducing the auxiliary functions

$$F^{i,j,k} = e^{-2d_jK_j}S^{j,k}R^{i,j} + 1,$$

$$G^{i,j,k} = e^{-2d_jK_j}R^{i,j}T^{j,k} + R^{j,k},$$

$$H^{i,j,k} = S^{i,j}R^{i,j}T^{j,k} + e^{-2d_jK_j}T^{i,j}T^{j,k},$$

and (henceforth, we will assume all the cavities to be equal and consider only the indices $\{ijk\} = \{012\}$)

$$I_1 = E^{012},$$

$$I_2 = F^{012}e^{-2d_2K_2}G^{012},$$

$$I_n = F^{012}e^{-2d_2K_2}\left(H^{012}e^{-2d_2K_2}\right)^{n-2}G^{012},$$

we can proceed to compute the generating functions.

### 2.1. The dielectric case

Let us consider Casimir cavities made of dielectric layers (of thickness $d_i$). To obtain the general expression for the $\Delta$ functions we can proceed inductively (a very detailed discussion up to three cavities can be found in Ref. [2]). For the cavity characterised by the numbers (012) in Fig. 1, with $\epsilon_0 = \epsilon_2$, the generating function, for TM and TE modes, respectively, is obtained in the usual manner [2, 10] (see appendix). After regularization, i.e., setting to zero the Casimir energy when the two cavities are infinitely far away, the result can be written as $\Delta_1 = E^{012} = I_1$. Let us now consider two cavities [(012), (234) in Fig. 1]. In this case, the generating function is the determinant of the $8 \times 8$ matrix made by the first rows and columns of the matrix given in the appendix [7]. It can be written as a $2 \times 2$ block...
matrix, thus \[17, 18\]

\[
\Delta = \det \begin{pmatrix} A & B \\ C & D \end{pmatrix} = \det(A) \det(1 - A^{-1}BD^{-1}) \det(D),
\]

where \{A, B, C, D\} are 4 \times 4 matrices, with \(\det(A) = \det(D) = \Delta_1\).

When the two cavities are infinitely far away from each other \((d_2 \to \infty)\), \(C = 0\), \(\Delta = \det(A) \det(D) =: \Delta_2\) and the Casimir energy will be simply the sum of the energies of the two cavities, \(\log(\Delta_2) = \log(\Delta_1^2) = 2 \log(\Delta_1)\). When they are brought at a distance \(d_2\) from each other, in addition to the previous energy, there is the interaction energy accounted for by the term \(\det(1 - A^{-1}BD^{-1}C)\). In this case \(\Delta_2 = \det(A) \det(D) \det(1 - A^{-1}BD^{-1}C)\) and, after regularization, it can be written (see appendix) as \(\Delta_2 =: I_1^2 + I_2\), so that the corresponding Casimir energy depends on \(\log(\Delta_2) = \log(I_1^2 + I_2) = \log(I_1^2) + \log(1 + I_2/I_1^2)\).

The first term is simply the sum of the energies of the two cavities taken independently, the second term is the interaction energy between the two. Therefore we can always reduce ourselves to the computation of determinants of products of 4 \times 4 matrix. The interaction in the case of \(n \geq 3\) cavities is accounted for by the term \(I_n\). In this manner, using the inductive principle, it is not difficult to convince oneself that the generic \(\Delta_N\) functions for the case of \(N\) dielectric cavities can be obtained in the following manner (a sort of Feynman diagram for the generating functions): let us define \(\{k_1, k_2, \ldots, k_J\}\) to be the \(J\)-th integer partition of \(N\) and \(Q_J\) its multiplicity (the number of combinations that contain the same type of \(I_k\) but in a different position) then

\[
\Delta_N = \sum_J Q_J \left( I_{k_1} I_{k_2} \ldots I_{k_J} \right).
\]

So, for example,

\[
\begin{align*}
\Delta_1 &= I_1, \\
\Delta_2 &= (I_1)^2 + I_2, \\
\Delta_3 &= (I_1)^3 + I_1 I_2 + I_2 I_1 + I_3 = (I_1)^3 + 2I_1 I_2 + I_3, \\
\Delta_4 &= I_4 + I_1 I_3 + I_3 I_1 + I_2^2 + I_1 I_1 I_2 + I_1 I_2 I_1 + I_2 I_1 I_1 + I_1^4 \\
&= I_4 + 2I_1 I_3 + I_2^2 + 3I_1^2 I_2 + I_1^4,
\end{align*}
\]

and, e.g.,

\[
\begin{align*}
\Delta_{10} &= I_1^{10} + 9I_1^9 I_2 + 28I_1^8 I_2^2 + 35I_1^7 I_2^3 + 15I_1^6 I_2^4 + I_2^5 + 8I_1^5 I_3 + 42I_1^4 I_2 I_3 + 60I_1^3 I_2^2 I_3 + 60I_1^2 I_2^3 I_3 + 15I_1^4 I_3^2 + 30I_1^3 I_2^2 I_3 + 6I_1^2 I_2^3 + 4I_1 I_2^4 + 7I_1 I_3^2 + 30I_1 I_2 I_3^2 + 30I_1 I_2^2 I_4 + 4I_2^3 I_4 + 20I_1^2 I_3 I_4 + 24I_1 I_2 I_3 I_4 + 3I_2^3 I_4 + 6I_1^2 I_4^2 + 3I_2 I_4^2 + 6I_1 I_5 + 20I_1 I_2 I_5 + 12I_1 I_3 I_5 + 12I_1^2 I_2 I_5 + 6I_2 I_3 I_5 + 6I_1 I_4 I_5 + I_2^2 + 5I_1^2 I_6 + 12I_1 I_2 I_6 + 3I_2 I_6 + 6I_1 I_3 I_6 + 2I_4 I_6 + 4I_1^3 I_7 + 6I_1 I_2 I_7 + 2I_3 I_7 + 3I_1^2 I_8 + 2I_2 I_8 + 2I_1 I_9 + I_{10},
\end{align*}
\]

for ten cavities.
2.2. The Plasma Sheets case

These formulae can be extended to the case in which the layers are characterised as plasma sheets. For example, the two dielectric cavities (012) and (234) can describe three plasma-sheet cavities, (012), (123), (234), by imposing \( \epsilon_i = 1 \), and \( \Omega \neq 0 \). In other words, two dielectric cavities need four layers located at 0, \( d_1 \), \( d_1 + d_2 \), \( d_1 + d_2 + d_3 \) but the same four layers correspond to three cavities having plasma sheet as boundaries. Consequently \( N_{ps} \) (odd) plasma sheets can be obtained by \( n = \frac{N_{ps} + 1}{2} \) standard dielectrics by simply imposing \( \epsilon_i(i\zeta) = 1 \), and the extension of the previous formulae to the case of an odd number of plasma sheets is straightforward.

The case of an even number of plasma sheets is more involved. It can be obtained starting with \( N_{ps} + 1 \) (\( N_{ps} \) even) cavities and moving the last layer to infinity. From the mathematical point of view, this procedure corresponds to introducing a term \( I_n' \) (which describes the interaction of the last interface with all the others), defined like as

\[
I'_1 = 1; \quad I'_n = \lim_{G \to G'} I_n, \quad \text{if } n \geq 2; \quad \text{with } G' ij = S'^{ij}.
\] (2)

In this manner, we have for two and four plasma sheet (please note that it is necessary to perform the limiting procedure first and then to group together the various terms)

\[
\Delta^p_{2s} = \lim_{G \to G'} \Delta^p_{2+1} = \lim_{G \to G'} \Delta^p_2 = \lim_{G \to G'} \left[ (I_1)^2 + I_2 \right] = I_1 I'_1 + I'_2 = I_1 + I'_2; \quad (3)
\]

\[
\Delta^p_{3s} = \lim_{G \to G'} \Delta^p_{4+1} = \lim_{G \to G'} \Delta^p_3 = \lim_{G \to G'} \left[ (I_1)^3 + I_1 I_2 + I_2 I_1 + I_3 \right] = I_1 I'_1 + I'_2 I'_2 + I'_2 I'_1 + I'_3 = I'_1 + I_2 + I'_1 I'_2 + I'_3. \quad (4)
\]

The fact that only one term at a time takes the prime corresponds to the fact that the last cavity only must be sent to infinity.

3. NUMERICAL RESULTS

We are now in the position to discuss the dependence of the Casimir Energy of a \( N \)-cavity made of \( N \)-plasma sheets.

We start by considering the variation of the Casimir energy as a function of the number of cavities for fixed thickness \( d_i = 2 \) nm and \( \Omega = \frac{\omega_0 da d^2}{\mu} = 49593.3 \) m\(^{-1} \) (see Refs. [16, 19]). We get \( E[N] \) = 0.000197 J m\(^{-2} \) and, for the ratio \( \frac{E[N]}{NE[1]} \) between the Casimir Energy of \( N \) cavities \( E[N] \), and the product \( NE[1] \) between the number of cavities and the energy of a single cavity \( E[1] \), we find the values quoted in the following table. (NB We underline the fact that the contribution of TE modes results various order of magnitude less than the one from TM modes. For this reason, in the following, it will be simply omitted)

The best fit is given by

\[
\frac{1}{N} \frac{E[N]}{E[1]} = 1.034 - \frac{0.034}{N^{0.71}}, \quad (5)
\]

that gives a clear indication of the presence of an asymptote for \( N \to \infty \). In Fig. 2 a comparison between the exact numerical result and the analytical fitted behaviour up to \( N = 19 \) [Eq. (5)] is shown.
| $N$ | $\frac{E[N]}{N E[1]}$ |
|-----|------------------|
| 1   | 1.0000           |
| 2   | 1.0125           |
| 3   | 1.0181           |
| 4   | 1.0212           |
| 5   | 1.0232           |
| 6   | 1.0246           |
| 7   | 1.0256           |
| 8   | 1.0263           |
| 9   | 1.0269           |
| 10  | 1.0274           |
| 11  | 1.0278           |
| 12  | 1.0284           |
| 13  | 1.0288           |
| 14  | 1.0292           |
| 15  | 1.0294           |

**TABLE I:** The ratio $\frac{E[N]}{N E[1]}$ as a function of the number of cavities

Thus, we obtained an asymptotic expression for the Casimir energy for large $N$,

$$E[N] \simeq (1.034 E[1]) N$$

and deduced that the coupling of the various cavities resulted in an increase of the Casimir energy of 3.4%. This result is very different from the result in the case of dielectric layers [7], in which a very strong coupling between different layers was found, mainly due to the zero Matsubara mode.

Remembering that [15] $E[1] = 5 \times 10^{-3} \hbar c \sqrt{\frac{\Omega}{d^4}}$, with $\Omega = \frac{n d q^2}{2m^* \alpha_0}$, it seems reasonable to assume $E[N]/A = -(1.034 N) K \hbar c \frac{\Omega}{d^4}$, estimating the best values for $K, \alpha, \beta$. We found $K = 5.0 \times 10^{-3}$, $\beta = 2.4998$ and $\alpha = 0.4998$, in perfect agreement with Ref. [15]. In conclusion the Casimir energy (per unit surface) of $N$ plasma sheet at fixed temperature $T = 94$K is given by

$$E[N]/A = -(1.034 K \hbar c \sqrt{\frac{\Omega}{d^4}}) N \left( J m^{-2} \right)$$

(7)

In Fig. 3 the exact values (dots) of the Casimir Energy as a function of $d$ are shown for $N = \{3, 11, 19\}$ and compared with the fitting formula, Eq. (7).

In Fig. 4 the Casimir Energy is plotted as a function of $\Omega$ for $N = \{10, 19\}$.
In conclusion, a good approximation for the Casimir Energy (at fixed temperature) for $N$ plasma-sheet cavities can be written as

$$\frac{E[N]}{A} = -\left(1.034 \, K \hbar c \frac{\sqrt{\Omega}}{d^{5/2}}\right) N = \left(-1.63 \times 10^{-28} (Jm)\right) \left(N \frac{\sqrt{\Omega}}{d^{5/2}} (m^{-3})\right), \quad (8)$$

with $E[N]/A$ measured in $Jm^{-2}$.

Based on the above formulae, in the following section we give an estimate for the variation of the Casimir energy across the metal-superconductor transition.

4. THE VARIATION OF THE CASIMIR ENERGY IN THE YBCO

The typical structure of a YBCO cell is represented in Fig.5 in which $\delta = 4.25\text{Å}$ is the thickness of our plasma sheet and $d = 3.18\text{Å}$ is the distance between the layers.
FIG. 4: A comparison between exact values of the Casimir energy (dots) and the approximated formula (lines), for $d = 2$ nm, with $\Omega$ expressed in nm$^{-1}$ $E/A$ in $J/m^2$.

FIG. 5: Typical layered structure of $YBa_2Cu_3O_7$ [20].

By observing that [16] $\Omega(0) = \frac{\delta}{2\lambda_{ab}(0)}$, at $T = 0$ K, we can write for the Casimir energy of one cavity in the superconducting state as

$$\frac{E(0)}{A} = -1.63 \times 10^{-28} \sqrt{\frac{\delta}{2d^5}} \frac{1}{\lambda_{ab}(0)}. \quad (9)$$

Using the BCS relation $\lambda(T) = \frac{\lambda(0)}{\sqrt{1-(T/T_c)^2/3}}$ [20], corresponding to the case of $d$-wave pairing, as it is suitable for cuprates, for $T < T_c$ and for one cavity we get

$$\frac{E(T)}{A} = -1.63 \times 10^{-28} \sqrt{\frac{\delta}{2d^5}} \frac{1}{\lambda_{ab}(T)} = -1.63 \times 10^{-28} \sqrt{\frac{\delta}{2d^5}} \sqrt{1 - \frac{(T/T_c)^4}{3}} \frac{1}{\lambda_{ab}(0)}. \quad (10)$$
Thus, using for YBa$_2$Cu$_3$O$_7$ [19], $T_c = 92$ K, $\lambda_{ab}(0) = 1415$ Å, $d = 3.36$ Å, and $\delta = 5.84$ Å, we have

$$\frac{E(90)}{A} = -9.51 \times 10^{-3}\sqrt{1 - (90/92)^{1/3}} = -0.001616 \text{ Jm}^{-2}. \quad (11)$$

For the normal phase, $T > T_c$, we will use the data (and formulae) of Ref. [21], where particular attention is paid to the treatment of semiconductors with degenerate electron gases. At $T = 100$ K, we have $n_{3D} = 3.1 \times 10^{25}$ m$^{-3}$, which implies $n_{2D} = \delta n_{3D} = (5.84 \times 10^{-10})(3.1 \times 10^{25}) = 1.810 \times 10^{16}$ m$^{-2}$, so that at $T = 94$ K, we have $n_{2D} = 1.317 \times 10^{16} \frac{94}{100} = 1.702 \times 10^{16}$ m$^{-2}$. Consequently, $\Omega = \frac{\mu_0 n_{2D}^2 e^2}{2m^*} = 300.505$ m$^{-1}$, and

$$\frac{E(94)}{A} = -1.63 \times 10^{-28}\sqrt{\frac{\Omega}{d^5}} = -0.001365 \text{ Jm}^{-2}.$$  

Thus,

$$\frac{\Delta E}{A} = \frac{E(94) - E(90)}{A} = 0.000251 \text{ Jm}^{-2}.$$  

As revealed by an inspection of the table in Ref. [19], it is clear that the previous results depend in a crucial way on the sample of YBCO used. A typical Resistance vs. Temperature curve of the YBCO crystals we are planning to use in the Archimedes experiment is reported in Fig. 6. Our reference values are $T_c = 89$ K and $\lambda_{ab}(0) = 1030$ Å [22], thus, assuming all the other parameters unaltered, we have $\frac{E(87)}{A} = -0.002258 \text{ Jm}^{-2}$ and, in the normal phase, $T = 91$ K, $\frac{E(91)}{A} = -0.001343 \text{ Jm}^{-2}$ so that $\frac{\Delta E}{A} = \frac{E(91) - E(87)}{A} = 0.0009142 \text{ Jm}^{-2}$.

5. CONCLUSIONS

We have proposed a model for computing the variation of the Casimir energy of a YBCO sample across the metal-superconductor transition.
We have constructed a powerful procedure to compute the renormalised Casimir energy both in the case of cavities made of a large number of thick dielectric layers and in the case of cavities made by a large number of thin plasma sheet layers.

Our main assumption is that the last case can be used to describe the Casimir energy in YBCO and, more generally in cuprates (BSCCO), because of their natural built-in layered structure, both in the normal and in the superconducting phase.

We suggested a possible way of characterising the variation of the Casimir energy at the metal-superconductor transition, giving a numerical estimate for the specific YBCO sample that we are using in the Archimedes experiment.

The computed value for the relative variation of the Casimir energy, for one cavity, is

$$\Delta \frac{E}{E} = 0.00091 \times 0.0013 = 0.7,$$

which is quite reassuring for the Archimedes experiment.

It must be noticed that our approach to the computation of the Casimir energy is still macroscopic. In order to fully describe its variation across the metal-superconductor transition, a microscopic description would be necessary. We do not have such a picture at the moment, but work is in progress in this direction.

Appendix A

The generating functions are obtained by imposing the most general boundary conditions at each singular layer located at $d_0, d_0+d_1, d_0+d_1+d_2$ etc. (see Fig. 1). These are obtained, as usual, by integrating the Maxwell equations

$$\nabla \cdot D = \rho, \quad \nabla \times E + \frac{\partial B}{\partial t} = 0,$$

$$\nabla \cdot B = 0, \quad \nabla \times H - \frac{\partial D}{\partial t} = J,$$

$$D = \epsilon E, \quad B = \mu H, \quad (\epsilon = \epsilon_0, \mu = \mu_0 \text{ in vacuum}),$$

across the discontinuity layers [12],

$$(D_i - D_{i-1}) \cdot n = \sigma, \quad (B_i - B_{i-1}) \cdot n = 0,$$

$$n \times (E_i - E_{i-1}) = 0, \quad n \times (H_i - H_{i-1}) = J,$$

where $n = \hat{z}$ is the normal to the layers (parallel to the $z$-axis, going from the $i$-th to the $i+1$-th layer), $\sigma$ is the surface charge density, and $J$ is the surface current density respectively (in principle they could be different at each layer, but we will not consider this situation). By virtue of the translational invariance in the $(x, y)$ plane we can set

$$E = f(z)e^{i(k_0|x_0| - \omega t)}, \quad B = g(z)e^{i(k_0|x_0| - \omega t)}.$$

In the following, when discussing the plasma sheet model, we will consider the so called hydrodynamic model [13] [14], in which a continuous fluid with mass $m^*$ and charge $q^*$ is uniformly distributed in the layer with an overall-neutralizing background charge. The fluid displacement $\xi$ is purely tangential, $\xi \equiv (\xi_x, \xi_y)$ with surface charge and current densities
related to the tangential component of the electric field $\mathbf{E}_\parallel$ by

$$\frac{\xi}{\mathbf{E}_\parallel} = q^* m^* \mathbf{E}_\parallel = q_0 \mathbf{E}_\parallel, \quad \mathbf{J} = n_{2D} q^* \xi = \sigma_0 \xi, \quad \sigma = -n_{2D} q^* \nabla_\parallel \cdot \mathbf{E} = -\sigma_0 \nabla_\parallel \cdot \mathbf{E};$$

$n_{2D}$ being the two dimensional carrier density in the layer, and $q^*$ and $m^*$ being their charge and mass, respectively. Under these assumptions, the most general boundary conditions at the $i = 1, 2, 3 \ldots$-th boundaries are

$$\epsilon_i(\omega) f^z_i - \epsilon_{i-1}(\omega) f^z_{i-1} = -\frac{\sigma_0 q_0}{\omega^2} \frac{\partial f^z_i}{\partial z}, \quad (A1)$$

$$\frac{\partial g^z_i}{\partial z} - \frac{\partial g^z_{i-1}}{\partial z} = 0, \quad \text{for the TM modes, and}$$

$$\frac{\partial g^z_i}{\partial z} - \frac{\partial g^z_{i-1}}{\partial z} = \Omega g^z_i, \quad (A2)$$

with $\Omega = \mu_0 \sigma_0 q_0$. With these boundary conditions, the generating functions for the TM and TE modes, respectively, can be written in terms of the auxiliary functions

$$i,j \quad R^{i,j}_{\text{TM}} = \frac{\epsilon_j(i\xi_0) K_i - \epsilon_i(i\xi_0) K_j - 2\Omega \xi_0 K_i K_j}{\epsilon_j(i\xi_0) K_i + \epsilon_i(i\xi_0) K_j + 2\Omega \xi_0 K_i K_j}, \quad R^{i,j}_{\text{TE}} = \frac{K_i - K_j + 2\Omega}{K_i + K_j + 2\Omega}$$

$$i,j \quad S^{i,j}_{\text{TM}} = \frac{\epsilon_j(i\xi_0) K_i - \epsilon_i(i\xi_0) K_j + 2\Omega \xi_0 K_i K_j}{\epsilon_j(i\xi_0) K_i + \epsilon_i(i\xi_0) K_j + 2\Omega \xi_0 K_i K_j}, \quad S^{i,j}_{\text{TE}} = \frac{K_i - K_j - 2\Omega}{K_i + K_j + 2\Omega}$$

$$i,j \quad T^{i,j}_{\text{TM}} = \frac{\epsilon_j(i\xi_0) K_i + \epsilon_i(i\xi_0) K_j - 2\Omega \xi_0 K_i K_j}{\epsilon_j(i\xi_0) K_i + \epsilon_i(i\xi_0) K_j + 2\Omega \xi_0 K_i K_j}, \quad T^{i,j}_{\text{TE}} = \frac{K_i + K_j - 2\Omega}{K_i + K_j + 2\Omega}$$

with $K_i = \sqrt{k_z^2 + \epsilon_i(i\xi_0) q_0^2}$, and $k_z = (k_x, k_y)$. Standard dielectric boundary conditions (dbc) are recovered by imposing $\Omega = 0$ and the plasma sheet boundary conditions (psbc) by requiring $\epsilon_j(i\xi_0) = 1, \quad \forall j$ (in this case $K_i = K_j$).

$$i,j \quad E^{ijk} = e^{-2d_j K_j} S^{i,j} R^{i,j} + 1,$$

$$i,j \quad F^{ijk} = e^{-2d_j K_j} R^{i,j} T^{i,j} + R^{i,j},$$

$$i,j \quad G^{ijk} = e^{-2d_j K_j} S^{i,j} T^{i,j} + S^{i,j},$$

$$i,j \quad H^{ijk} = S^{i,j} R^{i,j} + e^{-2d_j K_j} T^{i,j} T^{i,j}.$$

Considering henceforth all the cavities to be equal, we consider only the indices $\{ijk\} = \{012\}$, so that

$$I_1 = E^{012}; \quad I_2 = F^{012} e^{-2d_2 K_2} G^{012},$$

$$I_n = F^{012} e^{-2d_2 K_2} \left( H^{012} e^{-2d_2 K_2} \right)^{n-2} G^{012}, \quad \text{for } n \geq 3.$$

Let us consider, for the case of the TM modes, three cavities. Letting $x_i = \sum_{n=0}^{i} d_n$, the matching conditions give rise to the $12 \times 12$ matrix of coefficients
In Fig. 1, we find

\[ M = \begin{pmatrix}
-e^{-q_0} & e^{-q_1} & e^{-q_2} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
-e^{-q_0} & -e^{-q_1} & -e^{-q_2} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & e^{-q_1} & -e^{-q_2} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & e^{-q_1} & -e^{-q_2} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & e^{-q_2} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & e^{-q_2} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & e^{-q_2} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & e^{-q_2} & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & e^{-q_2} & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & e^{-q_2} & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & e^{-q_2} & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & e^{-q_2} & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & e^{-q_2} & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & e^{-q_2} \\
\end{pmatrix} \]

Computing the determinant of the minors of dimensions 4, 8, and 12, we obtain the energy of one, two, and three cavities, respectively. After regularization, for the single cavity (012) in Fig. 1, we find

\[ \Delta_1 = E^{012} = I_1. \]  \hspace{1cm} (A3)

For two cavities (012 – 234), we find

\[ \Delta_2 = E^{012}E^{234} + e^{-2(d_2 k_2)}F^{012}G^{234} =: (I_2)^2 + I_2, \quad \text{and} \]

\[ \log \Delta_2 = \log (I_1^2) + \log \left(1 + \frac{I_2}{I_1^2}\right). \]  \hspace{1cm} (A4)

Finally, for the three cavities, we find

\[ \Delta_3 = E^{012}E^{234}E^{456} + e^{-2(d_2 k_2 + d_4 k_4)}F^{012}H^{234}G^{456} + e^{-2d_2 k_2}E^{012}F^{234}G^{456} + e^{-2d_4 k_4}E^{012}F^{234}G^{456} =: I_3^3 + I_3 + I_1 I_2 + I_1 I_2, \]

\[ \log \Delta_3 = \log (I_3^3) + \log \left(1 + \frac{2I_1 I_2}{I_3}\right) + \log \left(1 + \frac{I_3}{I_1^3 + 2I_1 I_2}\right). \]  \hspace{1cm} (A5)

When \(d_2 \rightarrow \infty, I_2 \rightarrow 0\) and

\[ \log \Delta_2 = \log I_1^2 = 2 \log I_1. \]

Thus, when the two cavities are far away, their energy is simply the sum of the individual contributions and \(I^{(2)}\) can be seen as the energy due to the coupling of the two cavities (012) – (234). For the three cavities (012 – 234 – 456), the formulas are written so as to make evident the contribution to the energy resulting from the sum of the energies of the single cavities, with respect to the one coming from the coupling of the two possible pairs of cavities (012 – 234), (234 – 456), and the one coming from the coupling of the three, \(I^{(3)}\).
