Abstract

This paper studies discrete nonholonomic mechanical systems whose configuration space is a Lie group \( G \). Assuming that the discrete Lagrangian and constraints are left-invariant, the discrete Euler–Lagrange equations are reduced to the discrete Euler–Poincaré–Suslov equations. The dynamics associated with the discrete Euler–Poincaré–Suslov equations is shown to evolve on a subvariety of the Lie group \( G \). The theory is illustrated with the discrete versions of two classical nonholonomic systems, the Suslov top and the Chaplygin sleigh. The preservation of the reduced energy by the discrete flow is observed and discrete momentum conservation is discussed.

1. Introduction

The theory of variational integrators for Lagrangian and Hamiltonian systems originated in [19,23,24]. It was further developed by a number of authors (see [4,15,16,18,25] for a more complete list of references and history). A very important feature of variational integrators is discrete momentum preservation: if the original continuous-time system has symmetry and conserves the momentum map, so does the associated discrete-time mechanical system.

In [6,14], the theory was extended to Lagrangian systems with nonholonomic constraints. In particular, it was shown in [6] that a discrete-time nonholonomic system conserves spatial momentum in the case of horizontal symmetry (see [3] for the definition of horizontal symmetry). However, the case of horizontal symmetry is not typical in nonholonomic mechanics. Apparently, Chaplygin [5] was the first to observe the link between symmetry and conservation of the components of the momentum along a moving frame (see also [29] and references therein). Therefore, it is natural to ask if the discrete momentum is preserved by
the discrete-time nonholonomic system associated with a momentum-preserving continuous-time system in the case of nonhorizontal symmetry. A closely related question is whether the discrete dynamics has an invariant measure. We point out that generically, continuous-time nonholonomic systems are not measure-preserving (see [12, 28] for details).

This paper studies both the local and the global properties of the numerical variational integrators for a nonholonomic mechanical system, whose configuration space is a Lie group \( G \). Here we consider LL systems, that is, we assume that both the Lagrangian and the constraint distribution are invariant with respect to the induced left action of the Lie group \( G \) on \( TG \) and \( G \times G \), the phase spaces of the continuous-time and the discrete-time systems, respectively.

This paper is organized as follows: section 2 gives a brief overview of both continuous and discrete-time nonholonomic dynamics. In particular, the discrete Lagrange–d’Alembert principle is reviewed.

In section 3, nonholonomic LL systems on a Lie group \( G \) are described. The invariance of the discrete Lagrangian and constraints with respect to the left diagonal action of \( G \) on \( G \times G \) enables one to introduce the discrete Euler–Poincaré–Suslov equations that govern the discrete momentum dynamics. Unlike the continuous-time case, the discrete momentum is shown to evolve on a nonlinear subvariety of the dual Lie algebra \( g^* \) of the Lie group \( G \).

In sections 4 and 5 the dynamics of the classical nonholonomic LL systems on the Lie groups \( SO(3) \) and \( SE(2) \)—the Suslov problem and the Chaplygin sleigh—are reviewed. The multidimensional generalizations of these problems are also treated.

In sections 6 and 7, the discrete Suslov problem and the discrete Chaplygin sleigh are introduced and studied. The discrete flows are shown to be iterations of multi-valued maps on certain two-dimensional non-orientable subvarieties of the Lie groups \( SO(3) \) and \( SE(2) \). Each of these discrete models retains the existence of heteroclinic trajectories that connect the two one-parameter families of relative equilibria, which is a distinct feature of the continuous-time dynamics. If, for special values of parameters, the continuous-time system is momentum/measure preserving, then so is its discrete analogue.

Moreover, in both of the discrete models the corresponding reduced constrained energy is preserved as well. This property is quite unexpected; indeed, generically the discrete variational integrators, including the nonholonomic ones, do not preserve the energy.

Many other interesting problems, such as the dynamics of the discrete systems with left-invariant Lagrangian and right-invariant constraints and the discrete momentum preservation in the general case when the configuration space is not a Lie group, stayed outside the scope of this paper. These problems will be addressed in future publications.

2. Lagrangian mechanics with nonholonomic constraints

In this section we discuss briefly the main concepts of continuous and discrete nonholonomic dynamics. For a complete exposition of the continuous-time model see, e.g., [1–3].

The Euler–Lagrange equations for nonholonomic systems. A nonholonomic Lagrangian system is a triple \( (Q, L, D) \), where \( Q \) is a smooth \( n \)-dimensional manifold called the configuration space, \( L : TQ \rightarrow \mathbb{R} \) is a smooth function called the Lagrangian and \( D \subset TQ \) is a constraint distribution. Recall that a distribution \( D \) is a collection of linear subspaces \( D_q \subset T_q Q \), one for each \( q \in Q \). Let \( q = (q^1, \ldots, q^n) \) be local coordinates on \( Q \). In the induced coordinates \((q, \dot{q})\) on the tangent bundle \( TQ \) we write \( L(q, \dot{q}) \). It is assumed that the

\[3\] In the continuous-time case, the momentum is restricted to a linear subspace of \( g^* \).
Lagrangian is hyperregular, i.e. the map
\[ \frac{\partial L}{\partial \dot{q}} : TQ \to T^*Q \]
is invertible (see [17]).

A curve \( q(t) \in Q \) is said to satisfy the constraints if \( \dot{q}(t) \in D_{q(t)} \) for all \( t \). The dynamics of the system is given by the following Lagrange–d’Alembert principle: the equations of motion for the system are those determined by
\[ \delta \int_a^b L(q^i, \dot{q}^i) dt = 0, \quad (2.1) \]
where we choose variations \( \delta q(t) \) of the curve \( q(t) \) that satisfy \( \delta q(a) = \delta q(b) = 0 \) and \( \delta q(t) \in D_{q(t)} \) for each \( t \in [a, b] \). This principle is supplemented by the condition that the curve itself satisfies the constraints. Note that we take the variation before imposing the constraints; that is, we do not impose the constraints on the family of curves defining the variation. This is known to be important for obtaining the correct mechanical equations (see, e.g., [1, 3] for a discussion and references).

Assuming that the constraint distribution is specified by a set of \( s \) differential forms \( A^j(q) \), \( j = 1, \ldots, s \), that is,
\[ D = \{ q \in TQ \mid \langle A^i(q), \dot{q} \rangle = 0, \quad j = 1, \ldots, s \} \quad (2.2) \]
equation (2.1) implies
\[ \frac{d}{dt} \frac{\partial L}{\partial \dot{q}} - \frac{\partial L}{\partial q} = \sum_{j=1}^s \lambda_j A^j(q). \quad (2.3) \]
Equations (2.3) are called the Euler–Lagrange equations with multipliers. Coupled with (2.2), they give a complete description of the dynamics of the system.

**Theorem 2.1.** Equations (2.3) conserve the energy
\[ E = \left( \frac{\partial L}{\partial \dot{q}}, \dot{q} \right) - L. \quad (2.4) \]
See [2] for the proof and discussion.

**The Euler–Poincaré–Suslov equations.** Now let the configuration space be an \( n \)-dimensional connected Lie group \( G \) with local coordinates \( g \). As usual, we use the notation \([\cdot, \cdot] : g \times g \to g\) for the antisymmetric bracket operation on the Lie algebra \( g = T_e G \) of the group \( G \). Define an \( LL \) system on \( G \) as a Lagrangian system \((G, L, D)\) with a left-invariant Lagrangian \( L : TG \to \mathbb{R} \) and a left-invariant (generally nonintegrable) distribution \( D \) on the tangent bundle \( TG \).

The Lagrangian \( L : TG \to \mathbb{R} \) is left-invariant if and only if \( L(g, \dot{g}) \) depends on \( (g, \dot{g}) \) through the body velocity operator \( \omega = g^{-1} \dot{g} = TL_q \dot{\gamma} \). Then there exists a function \( l : g \to \mathbb{R} \) called the reduced Lagrangian such that \( L(g, \dot{g}) = l(\omega) \).

A distribution \( D \subset TG \) is left-invariant if and only if there is a subspace \( \partial \subset g \) such that \( D_\partial = TL_\partial \partial \subset T_\partial G \) for any \( g \in G \). Let \( g^\ast \) be the dual of the Lie algebra \( g \) and let \( a^j \in g^\ast \), \( j = 1, \ldots, s \), be independent annihilators of the subspace \( \partial \), i.e.
\[ \partial = \{ \xi \in g \mid \langle a^j, \xi \rangle = 0, \quad j = 1, \ldots, s \}, \quad (2.5) \]
where \( \langle \cdot, \cdot \rangle : g^\ast \times g \to \mathbb{R} \) is the standard pairing. The left-invariant constraints on \( TG \) are defined by the equations
\[ \langle a^j, g^{-1} \dot{g} \rangle = 0, \quad j = 1, \ldots, s. \]
Define the body momentum $p : g \to g^*$ by the formula $p = \partial l / \partial \omega$. According to [13], the reduced dynamics of an LL system $(G, L, D)$ is governed by the Euler–Poincaré–Suslov equations with multipliers

$$
\dot{p} = \text{ad}^*_\omega p + \sum_{j=1}^s \lambda_j a^j
$$

(2.6)
coupled with the constraints (2.5). The dynamics of the group variables $g$ is obtained by solving the reconstruction equation

$$
\dot{g} = TL_g \omega.
$$

(2.7)

Remark. In the absence of constraints, equations (2.6) become the Euler–Poincaré equations, which conserve the spatial momentum $J = \text{Ad}^*_\omega p$. In the presence of nonholonomic constraints, neither the spatial nor the body momentum is conserved generically. The conditions for body momentum preservation are studied in [29].

**Theorem 2.2.** The Euler–Poincaré–Suslov equations conserve the reduced constrained energy

$$
E_c = [(p, \omega) - l(\omega)]_{\omega \in \mathcal{D}}.
$$

**Proof.** Observe that the reduced energy $(p, \omega) - l(\omega)$ equals the energy, as the Lagrangian is left-invariant. Since $\omega \in \mathcal{D}$ throughout the motion, the reduced constrained energy equals the energy along the trajectories of (2.6) and is therefore preserved$^4$. □

Let the reduced Lagrangian $l(\omega)$ be the quadratic form $l = \frac{1}{2} (\Omega, \omega)$, where $\Omega : g \to g^*$ is a symmetric non-singular inertia operator. In this case, $p = \Omega \omega$. Then constraints (2.5) imply that $p$ lies in the subspace

$$
\mathcal{D} = \{ (a^j, \Omega^{-1} p) = 0, \ j = 1, \ldots, s \} \subset g^*.
$$

It is often convenient to choose a basis $e_1, \ldots, e_n$ in the Lie algebra $g$ such that $a^j = e^{n-j+1}$, $j = 1, \ldots, s$. Let $\omega_i, p_i$ and $I_{ij}$ denote the components of $\omega$, $p$ and $\Omega$ relative to this basis, respectively. Then the formula representing the reduced constrained energy becomes

$$
\frac{1}{2} \sum_{i,j=1}^{n-s} I_{ij} \omega_i \omega_j = \frac{1}{2} \sum_{i,j=1}^{n-s} I_{ij} p_i p_j.
$$

(2.8)

Here and elsewhere, the quantities $I_{ij}$ represent the components of the inverse constrained inertia operator $(\Omega|_{\mathcal{D}})^{-1}$.

Discrete mechanical systems with nonholonomic constraints. According to [6], a discrete nonholonomic mechanical system on a smooth $n$-dimensional manifold $Q$ is specified by

(i) a discrete Lagrangian $L_\delta : Q \times Q \to \mathbb{R}$;
(ii) an $(n-s)$-dimensional distribution $D$ on $TQ$ given by equations (2.2);
(iii) a discrete constraint manifold $D_\delta \subset Q \times Q$, which has the same dimension as $D$ and satisfies the condition $(q, q) \in D_\delta$ for all $q \in Q$.

$^4$ We will see later that the discrete analogues of the reduced energy and the reduced constrained energy have different conservation properties.
The dynamics is given by the following discrete Lagrange–d’Alembert principle (see [6]):
\[ \sum_{k=0}^{N-1} (D_1 L_d(q_k, q_{k+1}) + D_2 L_d(q_{k-1}, q_k))\delta q_k = 0, \quad \delta q_k \in D_{q_k}, \quad (q_k, q_{k+1}) \in D_d. \]
Here \( D_1 L_d \) and \( D_2 L_d \) denote the partial derivatives of the discrete Lagrangian with respect to the first and the second inputs, respectively.

The discrete constraint manifold is usually specified by the discrete constraint functions
\[ F_j(q_k, q_{k+1}) = 0, \quad j = 1, \ldots, s. \quad (2.9) \]
The dynamics of a discrete nonholonomic system is represented by sequences \( \{(q_k, q_{k+1})\} \) that satisfy the discrete Lagrange–d’Alembert equations with multipliers
\[ D_1 L_d(q_k, q_{k+1}) + D_2 L_d(q_{k-1}, q_k) = \sum_{j=1}^{s} \lambda_j^k A^j(q_k), \quad (2.10) \]
where \( A^j(q) \) are the constraint one-forms from (2.2).

According to [6], the map \( (q_k, q_{k+1}) \mapsto (q_k, q_{k+1}) \) defined by equations (2.9) and (2.10) is a local diffeomorphism in a neighbourhood of the diagonal of \( Q \times Q \) if the matrix
\[
\begin{pmatrix}
D_1 D_2 L_d(q, q') & A^1(q) & \cdots & A^s(q) \\
D_2 F_1(q, q') & 0 & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
D_2 F_s(q, q') & 0 & \cdots & 0
\end{pmatrix}
\]
is invertible for each \( (q, q') \) from this neighbourhood.

One way of constructing the discrete Lagrangian is to set \( L_d = L \circ \Psi \), where \( \Psi : Q \times Q \to TQ \) is the discretization map. In this case, the discrete constraint manifold \( D_d \) has to be consistent with the distribution \( D \), that is, \( D_d \) has to be locally defined as \( A^j \circ \Psi = 0, j = 1, \ldots, s \). If the configuration space is \( \mathbb{R}^n \), it is natural to choose
\[ \Psi(q_k, q_{k+1}) = \left( \frac{q_{k+1} + q_k}{2}, \frac{q_{k+1} - q_k}{h} \right) \in T\mathbb{R}^n, \quad (2.11) \]
where \( h \in \mathbb{R}_+ \) is the time step (see [6, 16] for details). We emphasize that the discretization map is not unique and, hence, there are many ways to define the discrete Lagrangian \( L_d \) and the discrete constraint manifold \( D_d \) for a given nonholonomic system \( (Q, L, D) \).

3. Discrete Euler–Poincaré–Suslov equations

In this section we obtain the reduced equations of motion of discrete nonholonomic systems on Lie groups.

Continuous and discrete left-invariant Lagrangians. Let the configuration space be a Lie group \( G \) with local coordinates \( g \). Let the discrete Lagrangian \( L_d : G \times G \to \mathbb{R} \) be invariant with respect to the left diagonal action of \( G \) on \( G \times G \), that is,
\[ L_d(\gamma g_k, \gamma g_{k+1}) = L_d(g_k, g_{k+1}) \]
for any \( g \in G \).

Define the left incremental displacement by the formula \( W_k = g_k^{-1} g_{k+1} \in G \). Since \( L_d \) is left-invariant, there exists a function \( l_d : (G \times G)/G \cong G \to \mathbb{R} \) called the reduced
\[ 5 \]
discrete Lagrangian such that $L_d(g_k, g_{k+1}) = l_d(W_k)$. According to [16], one defines the discrete constrained Lagrangian $l_d$ associated with a given continuous left-invariant Lagrangian $L(g, \dot{g}) = l((\log W_k)/h)$, where $\log : G \rightarrow \mathfrak{g}$ is the (local) inverse of the exponential map $\exp : \mathfrak{g} \rightarrow G$ and $h \in \mathbb{R}_+$ is the given time step.

For a matrix group $G$, one can instead use the approximation $\log W_k h \approx W_k e^{h} = g^{-1}(g_k + 1 - g_k) h$ and define the discrete Lagrangian by the formula

$$L_d(g_k, g_{k+1}) = l(\frac{g_k^{-1}(g_{k+1} - g_k)}{h}).$$

(3.1)

For quadratic Lagrangians considered later in this paper the value of the time step $h$ does not influence the dynamics. We thus set $h = 1$ in the rest of this paper.

Similarly to [4, 16], we define the discrete body momentum $p_k : G \times G \rightarrow \mathfrak{g}^*$ by the formula

$$\langle p_k, \xi \rangle = -\frac{d}{ds} \bigg|_{s=0} L_d(g_k \exp(s\xi), g_{k+1}) = -\frac{d}{ds} \bigg|_{s=0} l_d(-s\xi, W_k),$$

(3.2)

for any $\xi \in \mathfrak{g}^*$. Definition (3.2) implies

$$p_k = -L^{*}_g D_1 L_d(g_{k-1}, g_k) = R^*_g l_d(W_k),$$

(3.3)

where $L^{*}_g : T^*G \rightarrow \mathfrak{g}^*$ and $R^*_g : T^*G \rightarrow \mathfrak{g}^*$ are the induced left and right actions, respectively.

Using (3.2), one defines the discrete Legendre transform

$$\mathcal{L} : G \times G \ni (g_k, W_k) \mapsto (g_k, p_k) \in G \times \mathfrak{g}^*,$$

which is invertible in a neighbourhood of the set $\{(g, p) \in G \times \mathfrak{g}^* \mid p = 0\}$, but may fail to be globally invertible.

**Discrete left-invariant constraints.** If the continuous constraint distribution $\mathcal{D}$ is left-invariant, it is natural to require that the discrete constraint manifold $\mathcal{D}_d$ is invariant with respect to the left diagonal action of $G$ on $G \times G$, that is,

$$\mathcal{F}_j(g_k, g_{k+1}) = \mathcal{F}_j(g_{k}, g_{k+1}) \quad \text{for any } g \in G, j = 1, \ldots, s.$$  

This implies that there exist functions $f_j : G \rightarrow \mathbb{R}$, $j = 1, \ldots, s$, such that

$$\mathcal{F}_j(g_k, g_{k+1}) = f_j(W_k).$$

Consequently, $\mathcal{D}_d \subset G \times G$ is completely defined by the constrained (or admissible) displacement subvariety

$$\mathcal{S} = \{f_1(W) = 0, \ldots, f_s(W) = 0\} \subset G,$$

that is, $\mathcal{D}_d = \{(g, g') \in G \times G \mid g^{-1}g' \in \mathcal{S}\}.$

The subvariety $\mathcal{S}$ passes through the identity element $e \in G$, and the tangent space $T_e \mathcal{S}$ coincides with the linear subspace $\mathfrak{d} \subset \mathfrak{g}$ associated with the left-invariant distribution $\mathcal{D} \subset TG$. Motivated by this, we define $\mathcal{S}$ as the union of all one-parameter subgroups $G_\eta$.

The definition of the discrete momentum (3.2) accepted in this paper varies slightly from that used in many publications,

$$\langle p_k, \xi \rangle = \frac{d}{ds} \bigg|_{s=0} L_d((g_{k-1} \exp(s\xi))).$$
generated by vectors $\eta \in \mathfrak{d}$, i.e. $S = \exp \mathfrak{d}$. In the vicinity of the identity element $e \in G$ one can equivalently write

$$S = \{W \in G \mid \log W \in \mathfrak{d}\}. \quad (3.4)$$

**Remark.** For an arbitrary subspace $\mathfrak{d} \subset \mathfrak{g}$, the set $\exp \mathfrak{d}$ is not necessarily a subvariety of $G$. In this paper we concentrate on the important case when $G$ contains a subgroup $H$ generated by a subalgebra $\mathfrak{h} \subset \mathfrak{g}$ such that the decomposition $\mathfrak{g} = \mathfrak{h} \oplus \mathfrak{d}$ forms a symmetric pair, that is,

$$[\mathfrak{h}, \mathfrak{h}] \subset \mathfrak{h}, \quad [\mathfrak{d}, \mathfrak{d}] \subset \mathfrak{h}, \quad [\mathfrak{h}, \mathfrak{d}] \subset \mathfrak{d}. \quad (3.5)$$

In this case the following property holds (see, e.g., [11]).

**Proposition 3.1.** If $\mathfrak{d}$ and $\mathfrak{h}$ form a symmetric pair, then the set $S = \exp \mathfrak{d}$ is a smooth submanifold of $G$ homeomorphic to either the symmetric space $G/H$ or to a quotient of $G/H$ resulting from a finite group action.

If conditions (3.5) are satisfied, the set $\exp \mathfrak{d}$ is known as the Cartan model of the symmetric space $G/H$. Also note that the tangent bundle $TS$ is not a subset of the left-invariant distribution $\mathcal{D} \subset TG$ since the latter is not integrable.

Using the Legendre transform $\mathcal{L}$, we conclude that the discrete momentum $p_k$ is restricted to the subvariety

$$\mathcal{U} = \mathcal{L}(S) = \{p \in \mathfrak{g}^* \mid p = R_{\eta}^* l^j(W), W \in S\} \subset \mathfrak{g}^*.$$

In the examples considered below, the map $S \to \mathcal{U}$ is invertible almost everywhere on $S$.

**Discrete Euler–Poincaré–Suslov equations.** Assume that the discrete Lagrangian $L_d : G \times G \to \mathbb{R}$, the discrete constraint manifold $\mathcal{D}_d \subset G \times G$ and the constraint distribution $\mathcal{D} \subset TG$ are left-invariant with respect to the induced left actions of $G$ on $G \times G$ and on $TG$, accordingly.

Define the *action sum* and the *reduced action sum* by the formulae

$$S_d = \sum_{k=0}^{N-1} L_d(g_k, g_{k+1}) \quad \text{and} \quad s_d = \sum_{k=0}^{N-1} l_d(W_k).$$

Recall that the distribution $\mathcal{D}$ is written as $\langle A^j(g), \dot{g} \rangle = 0, \ j = 1, \ldots, s$. According to [6], variations $\delta g_k$ satisfy the conditions $\langle A^j(g_k), \delta g_k \rangle = 0, \ j = 1, \ldots, s$, and $\delta g_0 = \delta g_N = 0$. For the left-invariant constraints given by (2.5), the admissible discrete variations are those $\delta g_k \in TG_0$, that satisfy the conditions

$$\langle a^j, g_k^{-1} \delta g_k \rangle = 0, \quad j = 1, \ldots, s, \quad k = 1, \ldots, N - 1. \quad (3.6)$$

The following theorem extends the results of Bobenko and Suris [4] and Marsden et al [16] to the nonholonomic setting.

**Theorem 3.2.** Let $L_d : G \times G \to \mathbb{R}$ be a left-invariant Lagrangian, $l_d : G \to \mathbb{R}$ be the reduced Lagrangian and $\mathcal{D} \subset TQ$ and $\mathcal{D}_d \subset Q \times Q$ be the constraint distribution and discrete constraint manifold, respectively. Then the following statements are equivalent:

(i) The sequence $\{(g_k, g_{k+1})\}_{k=0}^{N-1}$ is a critical point of the action sum $S_d : G^{N-1} \to \mathbb{R}$ for arbitrary constrained variations.

(ii) The sequence $\{(g_k, g_{k+1})\}_{k=0}^{N-1}$ satisfies the discrete Euler–Lagrange equations with multipliers

$$D_1 L_d(g_k, g_{k+1}) + D_2 L_d(g_{k-1}, g_k) = -\sum_{j=1}^{s} \lambda_j^k A^j(g_k) \quad (3.7)$$

coupled with the discrete constraint equation $\mathcal{F}_j(g_k, g_{k+1}) = 0$. 

(iii) The sequence \( \{W_k\}_{k=0}^{N-1} \) is a critical point of the reduced action sum \( S_d : G^N \to \mathbb{R} \) with respect to variations \( \delta W_k \), induced by the constrained variations \( \delta g_k \) and given by

\[
\delta W_k = W_k [g_k^{-1} \delta g_k + 1 - \text{Ad}_{g_k^{-1}} \delta g_k].
\]

(iv) The sequence \( \{W_k\}_{k=0}^{N-1} \) satisfies the equation

\[
l'_d(W_k)TL_{W_k} - l'_d(W_{k-1})TL_{W_{k-1}} = - \sum_{j=1}^s \lambda^j_k a^j
\]

coupled with the discrete constraint equation

\[
f_j(W_k) = 0, \quad j = 1, \ldots, s, \quad k = 1, \ldots, N - 1.
\]

**Proof.** We first prove the equivalence of (i) and (ii) following [6]. Recall that the variations \( \delta g_k \) vanish at \( k = 0 \) and \( k = N \). Computing the first variation of the discrete action sum \( S_d \), we obtain

\[
\delta S_d = \sum_{k=1}^{N-1} (D_1 L_d(g_k, g_{k+1}) + D_2 L_d(g_{k-1}, g_k)) \delta g_k.
\]

Here the variations \( \delta g_k \) are not independent and satisfy the conditions \( \langle A^i(g_k), \delta g_k \rangle = 0 \).

Next, we prove that (i) is equivalent to (iii). Note that \( L_d = l_d \circ \pi \), where \( \pi : G \times G \to (G \times G)/G \cong G \) is given by \( (g_k, g_{k+1}) \mapsto g_k^{-1} g_{k+1} \). Therefore, \( \delta S_d = \delta S_d \). The variation \( \delta W_k \) is computed to be

\[
\delta W_k = g_k^{-1} \delta g_k + g_k^{-1} \delta g_k g_k^{-1} g_{k+1} = g_k^{-1} g_{k+1} \delta g_k \]

which yields (3.8).

To prove the equivalence of (iii) and (iv), we use (3.8) to compute

\[
\delta S_d = \sum_{k=1}^{N-1} \left[ l'_d(g_k^{-1} g_k) TL_{g_k^{-1} g_k} - l'_d(g_k^{-1} g_{k+1}) TL_{g_k^{-1} g_{k+1}} \right] (g_k^{-1} \delta g_k).
\]

Since the variations \( \delta g_k \) satisfy conditions (3.6), \( \delta S_d = 0 \) if and only if (iv) holds.

We now rewrite (3.9) in the form of discrete momentum equations.

**Theorem 3.3.** The discrete momentum evolution is governed by the discrete Euler–Poincaré–Suslov equations

\[
p_{k+1} - \text{Ad}^*_{W_k} p_k = \sum_{j=1}^s \lambda^j_k a^j,
\]

where \( W_k \) is restricted to \( S \) and \( p_k \in U \subset g^* \).

**Proof.** Using definition (3.3), one has \( l'_d(W_k) = TR_{W_k}^* p_k \), and therefore for any \( \eta \in g \),

\[
l'_d(W_k)TL_{W_k} \eta = (TR_{W_k}^* p_k, TL_{W_k} \eta) = (TL^*_{W_k} TR_{W_k}^* p_{k-1}, \eta) = (\text{Ad}^*_{W_k} p_{k-1}, \eta).
\]

Similarly,

\[
l'_d(W_k) TL_{W_k} \text{Ad}_{W_k} \eta = (\text{Ad}^*_{W_k} p_k, \text{Ad}_{W_k} \eta) = (\text{Ad}^*_{W_k} \text{Ad}_{W_k} p_k, \eta) = (p_k, \eta).
\]

Thus, (3.9) becomes (3.10), where \( W_k \) is restricted to \( S \) and \( p_k \in U \subset g^* \).
generally multi-valued. Given \( p_k \), one evaluates \( p_{k+1} \) by

1. inverting the map \( p_k = R_{w_k}^* l(W_k) \) and finding the associated value(s) of \( W_k \).
2. calculating \( \text{Ad}^*_{w_k} p_k \).
3. projecting \( \text{Ad}^*_{w_k} p_k \) onto \( \mathcal{U} \) along the subspace span \( \{a^1, \ldots, a^s\} \).

Since the map \( B \) is multi-valued, one needs to make a choice of a branch of \( B \). A natural way of doing this is to start from a value of \( p_k \) whose norm is small and to select \( p_{k+1} \) of the smallest norm.

4. The Suslov problem

The first known example of an LL system, the Suslov problem, was originally introduced in 1902 in [22]. The Suslov problem studies the motion of a rigid body suspended at its centre of mass in the presence of a constraint that forces the projection of the body angular velocity along a direction fixed in the body to vanish.

**The classical Suslov problem.** Here we briefly review the dynamics of the Suslov problem. We refer the reader to [2, 22] for a complete exposition.

The configuration space for this problem is the group \( SO(3) \). The Lie algebra \( so(3) \) is isomorphic to the Euclidean vector space \( \mathbb{R}^3 \). The isomorphism \( \varphi : so(3) \rightarrow \mathbb{R}^3 \) is given by

\[
\varphi(\omega) = (\omega_1, \omega_2, \omega_3) \in \mathbb{R}^3, \quad \text{where} \quad \omega = \begin{pmatrix} 0 & -\omega_3 & \omega_2 \\ \omega_3 & 0 & -\omega_1 \\ -\omega_2 & \omega_1 & 0 \end{pmatrix} \in so(3).
\]

In this representation of \( so(3) \) the antisymmetric bracket operation is the standard vector product in \( \mathbb{R}^3 \). The elements of \( so(3) \), when viewed as vectors from \( \mathbb{R}^3 \), are typed in bold.

Let \( I = (I_{ij}) \) be the inertia operator of the body, \( I^{-1} = (I^{-1})^{ij} \) be its inverse and \( \omega \in \mathbb{R}^3 \) be the body angular velocity vector. The reduced Lagrangian equals \( l = \frac{1}{2} \langle I^{-1} \omega, \omega \rangle \). Let \( a \) be the direction, fixed in the body, of the vanishing component of the angular velocity. The constraint reads

\[
\langle a, \omega \rangle = 0. \quad (4.1)
\]

The Lagrangian and constraint are left-invariant with respect to the lifted action of \( SO(3) \) on \( TSO(3) \).

Using the Killing metric, one identifies the dual Lie algebra \( so^*(3) \) and the Lie algebra \( so(3) \). Using this identification, the body angular momentum \( M = \partial l / \partial \omega \) becomes an element of \( so(3) \), and the Euler–Poincaré–Suslov equations (2.6) written for the Suslov problem become

\[
\dot{M} = M \times \omega + \lambda a. \quad (4.2)
\]

Eliminating the Lagrange multiplier, we obtain

\[
\dot{M} = \frac{1}{\langle a, I^{-1} a \rangle} [a, M] (I^{-1} a \times \omega). \quad (4.3)
\]

Without loss of generality, let us choose \( a \) as the third vector of the body frame \( e_1, e_2, e_3 \). Then the constraint becomes \( \omega_3 = 0 \), and the momentum is restricted to the subspace

\[
\mathcal{D}^* = \{ I^{31} M_1 + I^{32} M_2 + I^{33} M_3 = 0 \}. \quad (4.4)
\]

Select \( (M_1, M_2) \) as coordinates in \( \mathcal{D}^* \). Then the momentum dynamics is governed by the equations

\[
M_1 = \frac{(I^{31} M_1 + I^{32} M_2) \omega_2}{I^{33}}, \quad M_2 = -\frac{(I^{31} M_1 + I^{32} M_2) \omega_1}{I^{33}}. \quad (4.5)
\]
The Suslov problem preserves both the energy $E = \frac{1}{2}(\|\omega, \omega\|)$ and the reduced constrained energy $E_c = E \big|_a$. If $a = e_3$, the reduced constrained energy becomes

$$E_c = \frac{1}{2}(\|l_{11}\omega_1^2 + 2\|l_{12}\omega_1\omega_2 + \|l_{22}\omega_2^2) = \frac{\|\omega_1 M_1^2 - 2\|l_{12}M_1M_2 + \|l_{11}M_2^2}{2(l_{11}l_{22} - (l_{12})^2}.$$  

(4.6)

The momentum trajectories in the $M_1M_2$-plane are the elliptic arcs that form the heteroclinic connections between the asymptotically stable and unstable equilibria.

The dynamics of the group variables for the Suslov problem is obtained by solving the reconstruction equation

$$\dot{g} = g\omega.$$  

The equilibria of (4.5) correspond to the steady-state rotations of the rigid body. The non-equilibrium trajectories of (4.5) generate the transitional solutions that asymptotically approach these steady-state rotations as $t \to \pm \infty$.

The generalized Suslov problem. Certain natural multidimensional generalizations of the Suslov problem were studied in [7,10,27]. The configuration space of an $n$-dimensional rigid body with a fixed point is the Lie group $SO(n)$. For a path $g(t) \in SO(n)$, the angular velocity of the body is defined as $\omega(t) = g^{-1}\dot{g}(t) \in so(n)$.

The reduced Lagrangian for the generalized rigid body is

$$l = \frac{1}{2}(\|\omega, \omega\|),$$  

(4.7)

where $\| : so(n) \to so^*(n)$ is a symmetric non-singular inertia operator, which is often defined by the formula

$$\|\omega = J\omega + \omega J \in so^*(n).$$  

(4.8)

Here $J$ is a symmetric positive-definite non-singular $n \times n$ matrix called the mass tensor (see, e.g., [7]). In view of (4.8), the body angular momentum has the form $M = J\omega + \omega J \in so^*(n)$.

Let $e_1, \ldots, e_n$ be an orthogonal (relative to the standard metric in $\mathbb{R}^n$) body frame, and let $e^1, \ldots, e^n$ be the dual basis, i.e. $\langle e^i, e_j \rangle = \delta^i_j$, where $\delta^i_j$ is the usual Kronecker delta. The generalized Suslov constraints are chosen to be

$$\langle e^i \wedge e^j, \omega \rangle = 0, \quad 1 \leq i < j \leq n - 1,$$  

(4.9)

as in [7], i.e. the angular velocity $\omega$ belongs to the subspace of matrices of the form

$$\begin{pmatrix}
0 & \ldots & 0 & \omega_{1n} \\
\vdots & \ddots & \vdots & \vdots \\
0 & \ldots & 0 & \omega_{n-1,n} \\
-\omega_{1n} & \ldots & -\omega_{n-1,n} & 0
\end{pmatrix}.$$  

(4.10)

This choice is motivated by the following interpretation of the classical Suslov constraint. Assuming $a = e_3$, constraint (4.1) restricts the infinitesimal rotations of the three-dimensional rigid body to the planes that pass through $e_3$. Building on this observation, it is natural to define the $n$-dimensional Suslov constraints by forcing the infinitesimal rotations into the two-dimensional subspaces of $\mathbb{R}^n$ that contain the vector $e_n$. The angular velocities corresponding to such infinitesimal rotations are those satisfying conditions (4.9). Hence, the dynamics of the multidimensional Suslov problem is governed by the equations with multipliers

$$\dot{M} = ad^*_\omega M + \sum_{1 \leq i < j \leq n-1} \lambda_{ij} e^i \wedge e^j$$  

coupled with the constraints (4.9). For $n = 3$ the Lie algebra $so(3)$ is isomorphic to $\mathbb{R}^3$ and (4.11) become equations (4.2).
Let $\Lambda : \mathfrak{d} \to \mathfrak{d}^*$ be the restriction of the inertia operator $\mathbb{I}$ onto the subspace $\mathfrak{d}$. The operator $\Lambda$ is non-singular, and its matrix relative to the basis $\{e_1 \wedge e_n, \ldots, e_{n-1} \wedge e_n\}$ is

$$\Lambda_{ij} = J_{ij} + J_{nn} \delta_{ij}, \quad i, j = 1, \ldots, n-1.$$ 

The off-diagonal entries $J_{ij}$, $1 \leq i < j \leq n-1$, can be annihilated by a suitable orthogonal transformation that leaves the vector $e_n$ and the constraints (4.9) unchanged. Put $\mathcal{J} = (J_{1n}, \ldots, J_{n-1,n})$ and $\sigma = (\omega_{1n}, \ldots, \omega_{n-1,n})$. Using (4.11), we obtain the following closed system for the variables $\omega_{1n}, \ldots, \omega_{n-1,n}$:

$$(J_{ii} + J_{nn}) \dot{\omega}_{in} = J_{in} (\omega_{2n} + \cdots + \omega_{n-1,n}) - (J_{1n} \omega_{1n} + \cdots + J_{n-1,n} \omega_{n-1,n}) \omega_{in},$$

or, in the vector form,

$$\Lambda \dot{\sigma} = (\sigma \wedge \mathcal{J}) \sigma.$$

(4.12)

The equations for the remaining components $\omega_{ij}$ determine the multipliers $\lambda_{ij}$. Equation (4.11) conserve the constrained energy

$$E = \frac{1}{2} \langle \Lambda \sigma, \sigma \rangle = \frac{1}{2} \langle \mathcal{M}, \Lambda^{-1} \mathcal{M} \rangle,$$

(4.13)

where $\mathcal{M} = (M_{1n}, \ldots, M_{n-1,n})$. Since $\Lambda$ is positive-definite, we obtain a dynamical system on an $(n-2)$-dimensional ellipsoid $Q = \{E(\sigma) = \text{const}\} \subset \mathfrak{d}$.

In the general case, when $\mathcal{J} \neq 0$, system (4.12) has a line of equilibria

$$\{\omega_{1n} = I_{1n} \tau, \ldots, \omega_{n-1,n} = I_{n-1,n} \tau \mid \tau \in \mathbb{R}\},$$

(4.14)

This line intersects the ellipsoid $Q$ at two points, $S^+$ and $S^-$, which correspond to the stable and unstable steady-state rotations of the body in certain two-dimensional planes, fixed in both space and body. As shown in [7], all non-equilibrium solutions of system (4.12) lying on the same ellipsoid form heteroclinic connections from $S^-$ to $S^+$, i.e. they approach $S^-$ as $t \to -\infty$ and $S^+$ as $t \to \infty$. The motion of the $n$-dimensional body in space is an asymptotic evolution from a steady-state rotation in a two-dimensional plane fixed in the body, with angular velocity $-\omega$, to a steady-state rotation in the same plane, with angular velocity $\omega$. The spatial orientations of the two-planes corresponding to the above steady-state rotations are typically not the same.

In the special case when $\mathcal{J} = 0$, i.e. when the linear space $\mathfrak{d} \subset \mathfrak{so}(n)$ is an eigenspace for the inertia operator $\mathbb{I}$, all of the solutions of systems (4.11) and (4.12) are equilibria. Thus, every motion of the body in space is a steady-state rotation. The reconstructed motion of the Suslov top on the group $SO(n)$ was studied in [27].

5. The Chaplygin sleigh

The mechanical system reviewed in this section was introduced and studied in 1911 by Chaplygin [5] (the work had actually been finished in 1906). See [2,5] for a detailed exposition.

The configuration space. The sleigh is a rigid body moving on a horizontal plane supported at three points, two of which slide freely without friction, whereas the third is a knife edge which allows no motion orthogonal to its direction. The configuration space of this dynamical system is $SE(2)$, the group of Euclidean motions of the two-dimensional plane $\mathbb{R}^2$, which we parametrize with coordinates $\theta$, the angular orientation of the blade, and $(x, y)$, the position of the contact point of the blade on the plane.

The Lagrangian and constraint in the body frame. Introduce a coordinate system called the body frame by placing the origin at the contact point and choosing the first coordinate axis in the direction of the knife edge and the second coordinate axis in the orthogonal direction.
Denote the angular velocity of the body by $\omega = \dot{\theta}$ and the components of the linear velocity of the contact point relative to the body frame by $v_1$ and $v_2$. The vector $(\omega, v_1, v_2)$ is regarded as an element of the Lie algebra $se(2)$.

The Lagrangian equals the kinetic energy of the body, which is the sum of the kinetic energy of the centre of mass and the rotational kinetic energy of the body. The position of the centre of mass is specified by the coordinates $(a, b)$ relative to the body frame. We do not assume here that $b = 0$ as in some models. We will see that $a$ is crucial to the qualitative behaviour of the system, whereas $b$ is irrelevant. Let $m$ and $J$ denote the mass and moment of inertia of the sleigh relative to the contact point, respectively.

The system is invariant with respect to the action of $SE(2)$ on $TSE(2)$ induced by the left action of $SE(2)$ on itself. The reduced Lagrangian is
\[
 l = \frac{1}{2}(J + m(a^2 + b^2))\omega^2 + m(v_1^2 + v_2^2) - 2mbv_1 - 2ma\omega v_2. 
\] (5.1)

The blade constraint reads
\[
v_2 = -\dot{x}\sin \theta + \dot{y}\cos \theta = 0. 
\] (5.2)

The dynamics of the Chaplygin sleigh. For the constrained motion, the angular momentum relative to the vertical axis through the contact point, $M$, and the components of the linear momentum relative to the moving frame, $(\Pi_1, \Pi_2)$, are computed to be
\[
 M = \frac{\partial l}{\partial \omega} = (J + m(a^2 + b^2))\omega - 2mbv_1, \quad \Pi_1 = \frac{\partial l}{\partial v_1} = m(v_1 - b\omega),
\]
\[
 \Pi_2 = \frac{\partial l}{\partial v_2} = ma\omega. 
\]

The reduced dynamics of the Chaplygin sleigh is governed by the momentum equations (see, e.g., [2])
\[
 \dot{M} = -\frac{a}{(J + ma^2)^2}(M + b\Pi_1)(mbM + (J + m(a^2 + b^2))\Pi_1), 
\]
\[
 \Pi_1 = \frac{ma}{(J + ma^2)^2}(M + b\Pi_1)^2, 
\] (5.3)

which are obtained from (2.6) by eliminating the Lagrange multiplier. In the particular case $b = 0$ they become
\[
 M = -\frac{aM\Pi_1}{J + ma^2}, \quad \Pi_1 = \frac{maM^2}{(J + ma^2)^2}. 
\] (5.4)

Equations (5.3) preserve the reduced constrained energy
\[
 \frac{mM^2 + 2mbM\Pi_1 + (J + m(a^2 + b^2))\Pi_1^2}{2m(J + ma^2)}, 
\] (5.5)

which is a positive-definite quadratic form.

We emphasize that the phase portrait of (5.3) is identical to that of the Suslov problem. Indeed, if $a = 0$, the nonholonomic momentum $(M, \Pi_1)$ is conserved. Therefore, the body angular velocity $\omega$ and the linear velocity along the blade $v_1$ are constants. The evolution of the configuration variables $(\theta, x, y)$ is determined from the reconstruction equation (2.7), which reads
\[
 \dot{\theta} = \omega, \quad \dot{x}\cos \theta + \dot{y}\sin \theta = v_1, \quad -\dot{x}\sin \theta + \dot{y}\cos \theta = 0. 
\] (5.6)

The solutions of (5.6) are
\[
 \theta = \theta_0 + \omega t, \quad x = x_0 + \frac{v_1}{\omega}\sin(\theta_0 + \omega t), \quad y = y_0 - \frac{v_1}{\omega}\cos(\theta_0 + \omega t) \quad \text{if } \omega \neq 0 
\]
Figure 1. The momentum dynamics and the contact point trajectory for the Chaplygin sleigh.

\[ \theta = \theta_0, \quad x = x_0 + t v_1 \cos \theta_0, \quad y = y_0 + t v_1 \sin \theta_0 \quad \text{if} \quad \omega = 0. \]

Therefore, the contact point of the blade and the plane moves generically along a circle at a uniform rate.

If \( a \neq 0 \), the dynamics of (5.3) is integrable as the reduced energy is conserved. The trajectories are either equilibria situated on the line \( M + b \Pi_1 = 0 \), or elliptic arcs, as shown in figure 1, left. Assuming \( a > 0 \), the equilibria located in the upper half plane are asymptotically stable (filled dots in figure 1, left), whereas the equilibria in the lower half plane are unstable (empty dots). The elliptic arcs form heteroclinic connections between the pairs of equilibria.

As the momentum evolves along an elliptic arc, the contact point traces an interesting trajectory shown in figure 1, right. This trajectory has a cusp as the speed of the contact point, \( |v_1| \), momentarily vanishes when the momentum trajectory intersects the line \( mb M + (J + m(a^2 + b^2)) \Pi_1 = 0 \), and asymptotically approaches uniform straight line motions as \( t \to \pm \infty \).

The shape of the generic trajectory of the contact point is predetermined by the inertia of the body and the position of the centre of mass relative to the blade, and is independent of the initial conditions. In particular, if \( b = 0 \), the trajectory of the contact point becomes axially-symmetric as shown in figure 7. Although the dynamics of the group variables (\( \theta, x, y \)) cannot be explicitly written, it is possible to compute the angle between the asymptotic directions of the dynamics of the contact point. See [5, 20] for details.

**The multidimensional Chaplygin sleigh.** We now briefly discuss the generalized Chaplygin sleigh, which is an \( n \)-dimensional rigid body moving in \( \mathbb{R}^n \) in the presence of certain nonholonomic constraints.

The configuration space of this dynamical system is the group \( SE(n) \), which has the structure of a semidirect product, \( SE(n) = SO(n) \circ\mathbb{R}^n \). The elements of \( SE(n) \) are written as \((g, x)\), where \( g \in SO(n) \) is the orthogonal rotation matrix that represents the orientation of the body and \( x \in \mathbb{R}^n \) is the position of a reference point of the body.\(^7\)

The elements of the Lie algebra \( se(n) \) are written \((\xi, v)\), where \( \xi \in so(n) \), \( v \in \mathbb{R}^n \) and the Lie bracket operation in \( se(n) \) is given by the formula \([ (\xi_1, v_1), (\xi_2, v_2)] = ( [\xi_1, \xi_2], \xi_1 v_2 - \xi_2 v_1 ) \).

\(^7\) The velocity of the reference point is typically constrained, as in the classical Chaplygin sleigh. For this reason the reference point is also called the contact point.
It is often convenient to represent the elements of $SE(n)$ by means of $(n+1) \times (n+1)$ matrices of the form
\[
\begin{pmatrix}
g & x \\
0 & 1
\end{pmatrix}.
\] (5.7)

The group operations in $SE(n)$ are represented by products and inversions of matrices (5.7).

The Lie algebra $se(n)$ of the group $SE(n)$ has the structure of a semidirect product $so(n) \circledast \mathbb{R}^n$. The elements of $se(n)$ are written $(\xi, v)$, where $\xi \in so(n)$ and $v \in \mathbb{R}^n$. The algebra $se(n)$ is isomorphic to the set of $(n+1) \times (n+1)$ matrices
\[
\begin{pmatrix}
\xi v & 0 \\
0 & 0
\end{pmatrix},
\] $\xi \in so(n)$, $v \in \mathbb{R}^n$
and the Lie bracket operation in $se(n)$ is given by the formula
\[
[(\xi_1, v_1), (\xi_2, v_2)] = ([\xi_1, \xi_2], \xi_1 v_2 - \xi_2 v_1).
\]

For a trajectory $(g(t), x(t)) \subset SE(n)$, the quantities $\omega = g^{-1} \dot{g}$ and $v = g^{-1} \dot{x}$ are the angular velocity of the body and the linear velocity of the reference point relative to the body frame, respectively. Let $a \in \mathbb{R}^n$ be the coordinates, relative to the body frame, of the centre of mass of the body, which in general is located off the reference point. Denote the mass of the body and the inertia operator with respect to the centre of mass by $m$ and $I$, respectively (recall that $I\omega = J\omega + \omega J$).

Then the reduced Lagrangian is
\[
l(\omega, v) = -\frac{1}{4} \text{Tr} (\eta J \eta^T) = \frac{1}{2} (I \omega, \omega) + m \|oa + v\|^2
\]
\[
= -\frac{1}{4} \text{Tr} (\omega(J + ma \otimes a)\omega) + m (ao, v) + \frac{m}{2} \langle v, v \rangle,
\] (5.8)
where
\[
\eta = \begin{pmatrix}
\omega & v \\
0 & 0
\end{pmatrix} \in se(n),
\]
\[\mathbb{J} = S \begin{pmatrix}
J & 0 \\
0 & m
\end{pmatrix} S^T
\]
\[S = \begin{pmatrix}
e & a \\
0 & 1
\end{pmatrix} \in SE(n).
\]

The body momentum $p = (M, \Pi)$ is an element of the dual Lie algebra $se^\ast(n)$ whose components are
\[
M = \frac{\partial l}{\partial \omega} \in so^\ast(n),
\]
\[\Pi = \frac{\partial l}{\partial v} \in \mathbb{R}^n,
\] (5.9)
that is, $M$ and $\Pi$ are the body angular and linear momenta, respectively. Straightforward evaluation of (5.9) leads to the formulæ
\[
M = (J + ma \otimes a)\omega + \omega(J + ma \otimes a) + m(v \otimes a - a \otimes v),
\]
\[\Pi = m(v + aoa).
\] (5.10)

Left-invariant constraints on $SE(n)$. There are numerous ways to introduce nonholonomic constraints for the generalized Chaplygin sleigh. For example, one can require that the velocity of the reference point be restricted to a subspace fixed in the body. For $n = 3$, systems with such constraints were studied in [20, 28].

Another natural choice is to define the constraint subspace $\mathfrak{d} \in se(n)$ to be the set of matrices of the form
\[
\begin{pmatrix}
0 & -\omega_{12} & \ldots & -\omega_{1n} & v_1 \\
\omega_{12} & 0 & \ldots & 0 & 0 \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
\omega_{1n} & 0 & \ldots & 0 & 0 \\
0 & 0 & \ldots & 0 & 0
\end{pmatrix}
\] (5.11)
that is, to impose Chaplygin-like constraints on the linear velocity and Suslov-like constraints on the angular velocity of the body. In particular, for $n = 2$ we obtain the classical Chaplygin constraint $v_2 = 0$, and (5.11) becomes

$$\begin{pmatrix} 0 & -\omega & v_1 \\
\omega & 0 & 0 \\
0 & 0 & 0 \end{pmatrix}.$$  

(5.12)

6. The discrete Suslov problem

Here we use the discrete Euler–Poincaré–Suslov equations (3.10) to construct the discretization of the Suslov problem considered in section 4.

The discrete Lagrangian. Let $g_k \in SO(n)$ be the orthogonal matrix that represents the position of the $n$-dimensional body.

Introduce the incremental finite rotation $\Omega_k = g_k^{-1} g_{k+1}$, which should be interpreted as the discrete analogue of the body angular velocity $\omega = g^{-1} \dot{g}$, as discussed in section 3. If $g_k = g$ and $g_{k+1} = g + h \dot{g} + O(h^2)$, then

$$\lim_{h \to 0} \frac{\Omega_k - e}{h} = \lim_{h \to 0} \frac{g_k^{-1} g_{k+1} - e}{h} = g^{-1} \dot{g} = \omega.$$  

(6.1)

Using the general approach, we compute the discrete Lagrangian and the reduced discrete Lagrangian for the Suslov problem to be

$$L_d(g_k, g_{k+1}) = \frac{1}{2} \text{Tr} (g_k J g_{k+1}^T),$$  

$$l_d(\Omega_k) = \frac{1}{2} \text{Tr} (\Omega_k J),$$  

(6.2)

where $J$ represents the mass tensor. According to definition (3.2), the discrete body angular momentum of the top is

$$M_k = \Omega_k J - J \Omega_k^T \in so(n).$$  

(6.3)

Using (6.1), one obtains $\lim_{h \to 0} M_k / h = \omega J + J \omega = M$, i.e. the angular momentum of the continuous-time Suslov problem.

The discrete constraints. Following the approach of section 2, we impose the discrete left-invariant constraints on $SO(n) \times SO(n)$ in the form of restrictions on the finite rotations $\Omega_k \in SO(n)$. In agreement with the continuous constraints (4.9), we assume that constrained rotations are the exponentials of the elements of the linear subspace

$$\mathfrak{d} = \text{span} \{e_1 \wedge e_n, \ldots, e_{n-1} \wedge e_n \} \subset so(n).$$

The properties of the incremental finite rotations for the discrete Suslov problem are stated in the following lemma.

Lemma 6.1. Let $\mathcal{S} = \text{exp} \mathfrak{d}$ and $\Omega \in \mathcal{S}$. Then:

(i) The components of the constrained finite rotation matrices $\Omega$ relative to the basis $e_1, \ldots, e_n$ satisfy the conditions

$$\Omega_{ij} = \Omega_{ji}, \quad \Omega_{in} = -\Omega_{ni}, \quad 1 \leq i, j \leq n - 1.$$  

(6.4)

(ii) The subvariety $\mathcal{S}$ is diffeomorphic to the projective space $\mathbb{P}^{n-1} = S^{n-1}/\mathbb{Z}^2$.

Given a point $(z_0, z_1, \ldots, z_{n-1})$ on the unit sphere $S^{n-1}$, the components $\Omega_{ij}$ are

$$\Omega_{ij} = \delta_{ij} - 2z_i z_j, \quad \Omega_{in} = -\Omega_{ni} = 2z_0 z_i, \quad \Omega_{mn} = 2z_0^2 - 1, \quad 1 \leq i, j \leq n - 1.$$  

(6.5)

8 Definitions (6.2) and (6.3) were originally introduced in [19].
Proof. (i) Any vector from the subspace \( \mathfrak{d} \subset \mathfrak{so}(n) \) can be represented as \( \theta u \wedge e_n \), where \( \theta \) is a scalar constant and \( u = (u_1, \ldots, u_{n-1}) \) is a unit vector in \( \text{span}(e_1, \ldots, e_{n-1}) \). The odd powers of matrices \( e_i \wedge e_n \) are skew-symmetric and have an \( (n-1) \times (n-1) \) zero block in the upper left corner, whereas the even powers are symmetric, with zero elements in the last row and last column. Hence, the exponential of any linear combination of \( e_i \wedge e_n \) satisfies (6.4).

(ii) The operator \( \exp(\theta u \wedge e_n) \subset \mathfrak{so}(n) \) represents the rotation by the angle \( \theta \) in the two-dimensional plane spanned by \( u \) and \( e_n \). Therefore,

\[
\exp(\theta u \wedge e_n) u = u \cos \theta - e_n \sin \theta,
\]

\[
\exp(\theta u \wedge e_n) e_j = e_j - u(e_j, u) + (u \cos \theta - e_n \sin \theta)(e_j, u), \quad 1 \leq j \leq n - 1,
\]

\[
\exp(\theta u \wedge e_n) e_n = e_n \cos \theta + u \sin \theta.
\]

The right-hand sides of the above formulae are the columns of the matrix \( \exp(\theta u \wedge e_n) \). Then, identifying \( \exp(\theta u \wedge e_n) \) with \( \Omega \) and setting

\[
\cos \frac{\theta}{2} = z_0, \quad u_i \sin \frac{\theta}{2} = z_i, \quad 1 \leq i, j \leq n - 1
\]

we arrive at expressions (6.5).

Formulae (6.6) and the trigonometric identities

\[
\sin \frac{\theta}{2} = -\sin \left( \pi - \frac{\theta}{2} \right), \quad \cos \frac{\theta}{2} = -\cos \left( \pi - \frac{\theta}{2} \right)
\]

imply that the opposite points \( z \) and \( -z \) on the unit sphere \( S^{n-1} \) correspond to the same constrained rotation \( \exp(\theta u \wedge e_n) \). Therefore, \( S = \exp \mathfrak{d} \) is diffeomorphic to \( \mathbb{R}^{n-1} \).

Remark. Conditions (6.4) are equivalent to the discrete left-invariant constraints

\[
\text{Tr}(g_k^{-1} e_j \wedge e_n g_{k+1} - g_{k+1}^{-1} e_j \wedge e_n g_k) = 0, \quad j = 1, \ldots, n - 1,
\]

on \( \mathfrak{so}(n) \times \mathfrak{so}(n) \).

The discrete constraints for the classical Suslov problem. Conditions (6.4) and formulae (6.5) in the three-dimensional case state that \( \Omega \) is a finite rotation about an axis parallel to the vector

\[(z_2, -z_1, 0) \in \text{span}(e_1, e_2) \subset \mathbb{R}^3.\]

Indeed, the group \( \mathfrak{so}(3) \) is covered twice by the unit sphere \( S^3 = \{q_0^2 + q_1^2 + q_2^2 + q_3^2 = 1\} \), where \( (q_0, q_1, q_2, q_3) \) are the Euler–Rodriguez parameters. Any matrix \( W \in \mathfrak{so}(3) \) can be written as

\[
W = \begin{pmatrix}
q_0^2 + q_1^2 - q_2^2 - q_3^2 & 2(q_1 q_2 + q_3 q_0) & -2(q_1 q_3 - q_2 q_0) \\
2(q_1 q_2 - q_3 q_0) & q_0^2 + q_2^2 - q_1^2 - q_3^2 & -2(q_2 q_3 + q_0 q_1) \\
-2(q_1 q_3 + q_2 q_0) & -2(q_2 q_3 - q_0 q_1) & q_0^2 + q_1^2 - q_2^2 - q_3^2
\end{pmatrix};
\]

see [26] for details. If \( q_0 = \cos \theta/2 \), the matrix \( W \) represents a rotation in \( \mathbb{R}^3 \) about the vector \( e = (q_1, q_2, q_3) \) by the angle \( \theta \).

Setting \( \Omega_{12} = \Omega_{23} \) in (6.7) implies \( q_3 = 0 \), and hence \( W \) is a rotation about an axis in the plane \( \text{span}(e_1, e_2) \). Therefore, the constrained rotations \( \Omega \in S \subset \mathfrak{so}(3) \) become

\[
\Omega = \begin{pmatrix}
2(q_0^2 + q_1^2) - 1 & 2q_1 q_2 & 2q_0 q_2 \\
2q_1 q_2 & 2(q_0^2 + q_2^2) - 1 & -2q_0 q_1 \\
-2q_0 q_2 & 2q_0 q_1 & 2q_0^2 - 1
\end{pmatrix}.
\]
After the substitution $q_1 = -z_2$, $q_2 = z_1$, $q_0 = z_0$, formula (6.8) becomes identical to parametrization (6.5). As a result, the set of constrained rotations in the three-dimensional space is diffeomorphic to the real projective plane $\mathbb{RP}^2 = S^2/\mathbb{Z}^2$. We emphasize that, in general, the $k$th position of the body, $g_k = \Omega_{k-1} \cdots \Omega_0$, is not a rotation in the plane span($e_1, e_2$).

Discrete momentum locus $U \subset so^\ast(3)$. In contrast to the continuous case, the discrete momentum $M_k$ does not evolve in a linear subspace in the dual Lie algebra $so^\ast(3)$. Instead, it belongs to the nonlinear algebraic variety $U \subset so^\ast(3)$ defined by equations (6.3) and (6.8).

If the tensor $J$ is diagonal in the frame $e_1, e_2, e_3$; $J = \text{diag}(J_1, J_2, J_3)$, then, in view of (4.8), the vector representation $M = \varphi(I/\Omega_1) = (M_{32}, M_{13}, M_{21})$ of the angular momentum reads

$$M = 2((J_2 + J_3)q_0q_1, (J_1 + J_3)q_0q_2, (J_1 - J_2)q_1q_2),$$

where the discrete time index $k$ has been omitted to avoid tedious notation. Here and below, without loss of generality, we always assume $q_0 \geq 0$.

As a result, $U$ coincides with the Steiner Roman surface in $\mathbb{R}^3$ given by the quartic equation

$$\frac{J_1 - J_2}{(J_2 + J_3)(J_1 + J_3)}M_1^2M_2^2 + \frac{J_1 + J_3}{(J_2 + J_3)(J_1 - J_2)}M_1^2M_3^2$$

$$+ \frac{J_2 + J_3}{(J_1 + J_3)(J_1 - J_2)}M_2^2M_3^2 - 2M_1M_2M_3 = 0$$

(6.9)

(see, e.g., [9, 21]).

In the general case, when $J$ is not diagonal, one recovers the parametrization

$$M = 2 \begin{pmatrix}
(J_{22} + J_{33})q_0q_1 - J_{12}q_0q_2 - (J_{13}q_1 + J_{23}q_2)q_2 \\
(J_{11} + J_{33})q_0q_2 - J_{12}q_0q_1 + (J_{13}q_1 + J_{23}q_2)q_1 \\
(J_{11} - J_{22})q_1q_2 - J_{12}(q_1^2 - q_2^2) - (J_{13}q_1 + J_{23}q_2)q_0
\end{pmatrix}.$$  

(6.10)

One can show that the components of $M$ satisfy an algebraic equation of the fourth degree, which generalizes (6.9) and is not shown here. The corresponding algebraic surface $U$ in $\mathbb{R}^3 = \{(M_1, M_2, M_3)\}$ has pinch points and self-intersections. One can show that if the quadratic form $(J_{22} + J_{33})q_1^2 - 2J_{12}q_1q_2 + (J_{33} + J_{11})q_2^2$ is positive-definite, any point $(M_1, M_2)$ has at most two real inverse images in $U$. An example of the surface $U$ and its circular section for an unbalanced inertia tensor is given in figure 2.
Discrete Euler–Poincaré–Suslov equations on $so^*(3)$.

In the case $G = SO(3)$, the discrete momentum equation with multipliers (3.10) becomes
\[
M_{k+1} = \Omega_k^T M_k \Omega_k + \lambda_k \begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix},
\]
where $M_k = \Omega_k J - J \Omega_k^T$ and the components of $\Omega_k$ are subject to the discrete constraint $\Omega_{12,k} = \Omega_{21,k}$. Equation (6.11) represents the dynamics of the discrete Suslov problem and defines the maps $B : \mathbb{R}^2 \to \mathbb{R}^2$ and $B^* : \mathcal{U} \to \mathcal{U}$, which are generally multi-valued. For $(q_1 : q_2 : q_0) \in \mathbb{R}^2$, we write $B(q_1 : q_2 : q_0) = (\tilde{q}_1 : \tilde{q}_2 : \tilde{q}_0)$.

To study map (6.11), we note that
\[
\psi(\Omega_k^T M_k \Omega_k) = \psi(J \Omega_k - \Omega_k^T J) = \Omega_k^T M_k
\]
where $M_k$ denotes the vector representation of the discrete momentum 10. Using (6.10), we rewrite (6.11) in the vector form
\[
M_{k+1} = M_k + 4 \begin{pmatrix} (J_{12} q_1 + J_{23} q_2) q_2 \\ -(J_{13} q_1 + J_{23} q_2) q_1 \\ -(J_{11} - J_{22}) q_1 q_2 + J_{12}(q_1^2 - q_2^2) - (J_{13} q_1 + J_{23} q_2) q_0 \end{pmatrix},
\]
which is a discrete analogue of equations (4.3). This also shows that the momentum increment $M_{k+1} - M_k$ is orthogonal to the axis of rotation directed along the vector $(q_1, q_2, 0) \in \mathbb{R}^3$.

The map $B : \mathbb{R}^2 \to \mathbb{R}^2$ given by (6.11) is evaluated as follows:

1. Given the input $(q_1, q_2, q_0), q_0 = \sqrt{1 - q_1^2 - q_2^2} \geq 0$, one uses (6.10) and (6.12) to find the components of $M_k$ and of $\psi(\Omega_k^T M_k \Omega_k)$, respectively.
2. Using the first two components of $M_{k+1}$, one evaluates $\tilde{q}_1$ and $\tilde{q}_2$ by solving the system of two algebraic equations
\[
M_{1,k+1} = (J_{12} \tilde{q}_1 + J_{23} \tilde{q}_2) \sqrt{1 - \tilde{q}_1^2 - \tilde{q}_2^2} - (J_{13} \tilde{q}_1 + J_{23} \tilde{q}_2) \tilde{q}_2,
\]
\[
M_{2,k+1} = (J_{11} + J_{23}) \tilde{q}_1 \tilde{q}_2 - J_{12} \tilde{q}_1 \tilde{q}_1 \sqrt{1 - \tilde{q}_1^2 - \tilde{q}_2^2} + (J_{13} \tilde{q}_1 + J_{23} \tilde{q}_2) \tilde{q}_1,
\]
which are derived from (6.10). These equations define two quadratic surfaces $Q_1$ and $Q_2$ in $\mathbb{R}^3 = \{(q_1, q_2, q_0)\}$ that are symmetric about the origin of $\mathbb{R}^3$. These surfaces intersect the unit sphere $|q_1|^2 + |q_2|^2 + |q_0|^2 = 1$ along certain curves $C_1$ and $C_2$, respectively. Each curve is a union of two ovals, which are symmetric about the origin of $\mathbb{R}^3$. One can show that the intersection of the curves $C_1$ and $C_2$ consists of four complex points and two or no real points in $\mathbb{C}P^2$. Thus, there are at most two distinct real solutions $(\tilde{q}_1^{(1)}, \tilde{q}_2^{(1)}, \tilde{q}_0^{(1)})$ with $\tilde{q}_0^{(1)} > 0$.

3. One chooses a solution $(\tilde{q}_1^{(1)}, \tilde{q}_2^{(1)}, \tilde{q}_0^{(1)})$, with positive $\tilde{q}_0^{(1)}$, and then finds the last component of $M_{k+1}$ by the formula
\[
M_{3,k+1} = (J_{11} - J_{22}) \tilde{q}_1 \tilde{q}_2 - J_{12} (\tilde{q}_1^2 - \tilde{q}_2^2) - (J_{13} \tilde{q}_1 + J_{23} \tilde{q}_2) \tilde{q}_0,
\]
which is obtained from (6.14) by replacing $k$ with $k + 1$ and $q$ with $\tilde{q}$.

---

9 The homogeneous coordinates on $\mathbb{RP}^n$ are written as $(q_1 : \ldots : q_n : q_0)$ in this paper.
10 Here and later, to simplify notation, we omit the discrete time index $k$ in the components of $q$. 
In summary, the map $M_k \mapsto M_{k+1}$ given by (6.11) has in general four complex and two real values. In order to select one of these two real branches, we either use some extra arguments, like the existence of a conservation law, or restrict ourselves to the case of sufficiently small $q_1$ and $q_2$, which correspond to the small rotations $\Omega$. In the latter case only one of the real solutions $(q_1^{(1)}, q_2^{(1)})$ is small, and it is natural to choose this small solution.

We now prove that the constrained energy (4.6) of the continuous Suslov system is preserved by the discrete system as well.

**Theorem 6.2.** The discrete Suslov system (6.11) preserves the reduced constrained energy

$$E_c(M_1, M_2) = (J_{11} + J_{33})M_1^2 + 2J_{12}M_1M_2 + (J_{22} + J_{33})M_2^2.$$  \hspace{1cm} (6.15)

Written as a function of $(q_0, q_1, q_2)$, (6.15) becomes the quartic conserved quantity

$$H = ((J_{22} + J_{33})q_1^2 - 2J_{12}q_1q_2 + (J_{11} + J_{33})q_2^2)$$

$$\times ((J_{13}q_1 + J_{23}q_2)^2 + [(J_{11} + J_{33})(J_{22} + J_{33}) - J_{12}^2]q_0^2).$$  \hspace{1cm} (6.16)

The proof is straightforward: substituting (6.10) into (6.15) and (6.12) into (6.15) produce identical outcomes.

The independence of the conservation law (6.15) from $M_3$ is quite natural because all of the branches of the map (6.11) belong to the same level of the reduced constrained energy. We emphasize that the (unconstrained) energy $\frac{1}{2}(M, I^{-1}M)$ of the continuous Suslov problem is not preserved in the discrete setting.

*The invariant curves on $\mathbb{R}P^2.*$ As follows from theorem 6.2, the map $B$ has invariant curves, which are either the intersections of the sphere $q_1^2 + q_2^2 + q_0^2 = 1$ with quartic surfaces $H(q) = c$ or, in the momentum space $so^*(3)$, intersections of the generalized quartic Steiner surface $\mathcal{U}$ and the elliptic cylinders defined by (6.15). Thus, the invariant varieties are algebraic curves of order eight.

Assume that the kinetic energy metric is positive-definite, then the quadratic form $(J_{22} + J_{33})q_1^2 - 2J_{12}q_1q_2 + (J_{11} + J_{33})q_2^2$ is also positive-definite and, as follows from (6.16), the real invariant curves on the upper hemisphere $0 \leq q_0 \leq 1$ are unions of two branches. For small positive values of $c$ one branch is a small oval around the origin $(0, 0)$, whereas the other branch is an oval close to the equator $[q_0 = 0]$ of the sphere. It may or may not intersect the equator. In the former case, the opposite points of intersection are identified. The above branches correspond to the two connected components of the intersection of the Steiner surface $\mathcal{U}$ and the cylinder.

As the energy value increases, the branches approach each other: the smaller one grows and the bigger one shrinks. At a certain critical value $c = c^*$, the branches touch at the two ‘saddle points’ and form two separatrices. At the next critical value $c^{**} > c^*$, the two branches shrink to the two ‘centre points’. There are no real invariant curves for $c > c^{**}$. Note that if $c = c^*$ or $c = c^{**}$, the elliptic cylinder (6.15) is tangent to the surface $\mathcal{U}$. The foliation of $\mathbb{R}P^2$ by invariant curves is illustrated in figure 3.

**Remark.** As pointed out in [19], in the absence of nonholonomic constraints, the map $M_k \mapsto M_{k+1}$ given by the discrete Euler–Poincaré equations (6.11) is multi-valued because, generically, the equation $M_k = \Omega_{12}J - J\Omega_{12}^T$ has multiple solutions. In the presence of the discrete constraint $\Omega_{12,k} = \Omega_{21,k}$, the equation $M_k = \Omega_{k}J - J\Omega_{k}^T$ generally has a unique solution (excluding the self-intersection points of $\mathcal{U}$). However, as we saw earlier, the choice of $\lambda_{k+1}$ or $M_{k+1}$ is not unique, and the map governing the dynamics of the discrete Suslov problem is multi-valued as well.

---

11 To simplify the exposition, we omit the denominator in (4.6).
The relative equilibria of the discrete Suslov problem. According to (6.13), if the initial values $q_1$ and $q_2$ satisfy the condition $J_{13}q_1 + J_{23}q_2 = 0$, then
\[ M_{1,k+1} = M_{1,k}, \quad M_{2,k+1} = M_{2,k}, \quad \psi(\Omega^T_k M_k \Omega_k)_3 = -M_{3,k}, \]
that is, the coadjoint action $M_k \mapsto \Omega^T_k M_k \Omega_k$ is the reflection with respect to the plane $\{M_3 = 0\}$. Therefore, it is natural to assign to the multiplier $\lambda_k$ the value that makes $M_{3,k+1}$ equal to $M_{3,k}$. Consequently, one of the branches of the map $B$ has a one-parameter family of equilibria. These equilibria are the points of the line
\[ \mathcal{P} = (S^2 \cap \{J_{13}q_1 + J_{23}q_2 = 0\})/\mathbb{Z}^2. \]

They represent the discrete analogues of the steady-state rotations of the body in the classical Suslov problem. According to (6.8), the points $(q_1, q_2, q_0)$ and $(-q_1, -q_2, q_0)$ on $\mathcal{P}$ correspond to the finite rotations $\Omega_1$ and $\Omega_1^T$, respectively. It follows from (6.13) that there are no equilibrium points outside the line $\mathcal{P}$. In particular, neither the saddle points nor the centres of the invariant foliation of $\mathbb{R}P^2$ are equilibria.

Finally, as in the continuous case, the only trajectories of the discrete Suslov problem with a balanced inertia tensor $J_{13} = J_{23} = 0$ are the equilibria, i.e. the discrete body momentum $M_k$ is preserved.

Remark. The geometry of the foliation of $\mathbb{R}P^2$ by invariant curves suggests a natural way of selecting a branch of the map $B$ in the general case. Namely, if the initial point $(q_1, q_2)$ lies in the open region $\mathcal{N} \subset \mathbb{R}P^2$ distinguished by the condition $0 < c < c^*$, i.e. $(q_1, q_2)$ represents either a relatively small, or a sufficiently large finite rotation $\Omega$, then the points $(q_1, q_2)$ and $(\tilde{q}_1, \tilde{q}_2)$ belong to the same connected component of the invariant curve. In other words, if the initial point lies in $\mathcal{N}$, one should select a real solution of (6.14) that has either the smallest or the largest norm $\tilde{q}_1^2 + \tilde{q}_2^2$. On the other hand, a real initial point $(q_1, q_2)$ that is located between the separatrices (i.e. $(q_1, q_2) \in \mathbb{R}P^2 \setminus \mathcal{N}$) necessarily produces a complex output $(\tilde{q}_1, \tilde{q}_2)$. In particular, when the initial point is at a centre, the next point is necessarily complex, although the value of the conservation law remains real.

If the branches of the map $B : \mathbb{R}P^2 \to \mathbb{R}P^2$ are chosen as just discussed, the discrete-time dynamics in the region $\mathcal{N}$ inherits all of the main properties of the continuous Suslov problem.
Namely, let $\Delta_-, \Delta_+, \Theta_-$ and $\Theta_+$ be the subsets of $\mathbb{R}^2$ defined by
\[
\Delta_- = \{J_{13}q_1 + J_{23}q_2 < 0\}, \\
\Delta_+ = \{J_{13}q_1 + J_{23}q_2 > 0\}, \\
\Theta_- = \{(J_{12}J_{13} + J_{22}J_{23} + J_{23}J_{33})q_1 - (J_{11}J_{13} + J_{12}J_{23} + J_{13}J_{33})q_2 < 0\}, \\
\Theta_+ = \{(J_{12}J_{13} + J_{22}J_{23} + J_{23}J_{33})q_1 - (J_{11}J_{13} + J_{12}J_{23} + J_{13}J_{33})q_2 > 0\}.
\]

**Theorem 6.3.** If the initial point $\mathbf{q} = (q_1, q_2)$ lies in $\mathcal{N} \subset \mathbb{R}^2$, then the sequence $\{\mathbf{q}_k\}$ belongs to the invariant curve through $\mathbf{q}$. As $k \to -\infty$, the sequence $\{\mathbf{q}_k\}$ approaches an unstable equilibrium on the half-line $\mathbb{P}_u = \mathbb{P} \cap \Theta_-$. As $k \to \infty$, the sequence $\{\mathbf{q}_k\}$ approaches a stable equilibrium on $\mathbb{P}_s = \mathbb{P} \cap \Theta_+$. Each sequence $\{\mathbf{q}_k\}$ lies entirely in either $\Delta_-$ or $\Delta_+$.

**Proof.** First, we describe the discrete dynamics in the subset $\mathcal{U}_0$ of the momentum surface $\mathcal{U}$ bounded by the condition
\[
(J_{11} + J_{33})M_1^2 + 2J_{12}M_1M_2 + (J_{22} + J_{33})M_2^2 < c^2.
\]
For this purpose we introduce new coordinates on the $M_1M_2$-plane:
\[
\mu_1 = (J_{11}J_{13} + J_{12}J_{23})M_1 + (J_{23}(J_{22} + J_{33}) + J_{12}J_{13})M_2, \\
\mu_2 = J_{23}M_1 - J_{13}M_2.
\]
Using parametrization (6.10), we rewrite $\mu_1$ and $\mu_2$ as
\[
\mu_1 = (J_{13}q_1 + J_{23}q_2)[Q + ((J_{11} + J_{33})(J_{22} + J_{33}) - J_{12}^2)q_0], \\
\mu_2 = Qq_0 - (J_{13}q_1 + J_{23}q_2)^2,
\]
where
\[
Q = (J_{12}J_{13} + J_{22}J_{23} + J_{23}J_{33})q_1 - (J_{11}J_{13} + J_{12}J_{23} + J_{13}J_{33})q_2.
\]
The inequalities $(J_{11} + J_{33})(J_{22} + J_{33}) - J_{12}^2 > 0$ and $q_0 \geq 0$ imply that the quantity in the square brackets in (6.17) is positive throughout the region $\mathcal{U}_0$. Hence, the segment of the straight line $\mu_1 = 0$ inside $\mathcal{U}_0$ is filled out with the equilibria of the map $\mathcal{B}$ as the quantity $J_{13}q_1 + J_{23}q_2$ vanishes from this segment. Points in $\mathcal{U}_0$ with positive (negative) values of $\mu_1$ correspond to the points in $\mathcal{N} \subset \mathbb{R}^2$ with positive (negative) values of $J_{13}q_1 + J_{23}q_2$.

Next, (6.13) implies
\[
\mu_{2,k+1} = \mu_{2,k} + 4(J_{13}q_{1,k} + J_{23}q_{2,k})^2
\]
and, therefore, the coordinate $\mu_2$ always increases, while the sequence $\{(\mu_{1,k}, \mu_{2,k})\}$ approaches the line $\mu_1 = 0$ along the ellipse $E_c(M_1, M_2) = \text{const}$. Then, as follows from (6.18), $\mu_2 < 0$, $Q < 0$ for $k \to -\infty$, and $\mu_2 > 0$, $Q > 0$ for $k \to \infty$. As a consequence, the unstable and stable equilibria fill out the sets $\mathbb{P}_u = \mathbb{P} \cap \Theta_-$ and $\mathbb{P}_s = \mathbb{P} \cap \Theta_+$, respectively.

From (6.13), $\mu_{1,k+1} - \mu_{1,k} = -(J_{13}q_{1,k} + J_{23}q_{2,k})Q$, and therefore,
\[
\mu_{1,k+1} = (J_{13}q_{1,k} + J_{23}q_{2,k})(J_{11} + J_{33})(J_{22} + J_{33}) - J_{12}^2)q_{0,k}.
\]
This formula and (6.17) imply that $\mu_{1,k}$ and $\mu_{1,k+1}$ are always of the same sign unless $J_{13}q_1 + J_{23}q_2 = 0$, i.e. the sequence $\{(\mu_{1,k}, \mu_{2,k})\}$ lies entirely in either $\mathcal{U}_0 \cap \{\mu_1 < 0\}$ or $\mathcal{U}_0 \cap \{\mu_1 > 0\}$.

Reformulating these properties for the dynamics in the region $\mathcal{N} \subset \mathbb{R}^2$, we arrive at the statement of the theorem. □
For the foliation in figure 3, the corresponding discrete-time dynamics in the neighbourhood of the origin of the $M_1M_2$-plane is shown in figure 4, where stable and unstable equilibria are the filled and empty dots, respectively. As follows from theorem 6.3,

$$\lim_{k \to \infty} \Omega_k = \left( \lim_{k \to -\infty} \Omega_k \right)^{-1} = \text{const},$$

i.e. the discrete trajectories in the group $SO(3)$ approach the discrete steady-state rotations as $k \to \pm \infty$, which agrees perfectly with the asymptotic behaviour of the continuous-time Suslov problem.

The discrete Euler–Poincaré–Suslov equations on $so^*(n)$. We now briefly discuss the case $G = SO(n)$, which retains all of the main features of the continuous $n$-dimensional Suslov problem.

The discrete momentum equation (3.10) is

$$M_{k+1} = \Omega_{k+1}^T M_k \Omega_k + \sum_{1 \leq i < j < n} \lambda_{ij} e^i \wedge e^j, \quad M_k = \Omega_k J - J \Omega_k^T,$$

(6.19)

where, as above, $e_1, \ldots, e_n$ is an orthonormal body frame, and the components of $\Omega_k$ are parameterized by the coordinates $(z_0 : z_1 : \ldots : z_{n-1})$ on $\mathbb{RP}^{n-1}$ as in (6.5). In this case, the momentum $M$ belongs to an $(n-1)$-dimensional algebraic surface $\mathcal{U}$ in $so^*(n) = \mathbb{R}^{n(n-1)/2}$.

Let $\pi$ be the projection $so^*(n) \to \mathbb{R}^{n-1} = \{ (M_{1n}, \ldots, M_{n-1,n}) \}$. The inverse image of a generic point in $\pi(\mathcal{U}) \subset \mathbb{R}^{n-1}$ is a union of a finite number of points in $\mathcal{U}$. Hence, one needs to choose one of many possible values of the multipliers $\lambda_{ij}$. Thus, (6.19) should be regarded as a multi-valued map $B : \mathbb{R}^{n-1} \to \mathbb{R}^{n-1}$.

Recall that $\Lambda : \mathfrak{d} \to \mathfrak{d}^*$ is the restriction of the inertia operator $\mathbb{I} : so(n) \mapsto so^*(n)$ onto the subspace $\mathfrak{d}$. It is nondegenerate and in the above basis in $\mathfrak{d}$ is given by the $(n-1) \times (n-1)$ matrix

$$\Lambda_{ij} = J_{ij} + J_{in} \delta_{ij}, \quad i, j = 1, \ldots, n - 1.$$
Next, equations (6.19) yield
\[ M_{k+1} = 2z_0 \Lambda Z_k + 2(Z_k \wedge J)Z_k = M_k + 4(Z_k \wedge J)Z_k. \] (6.21)

As seen from (6.21), the discrete Euler–Poincaré–Suslov equations on so^*(n) have a line \( \ell \) of equilibria, which is the image of the projective line \( \mathbb{P} \subset \mathbb{R}^{n+1} \) defined by the equation \( Z_k \wedge J = 0 \), or, in coordinates,
\[ (z_1 : z_2 : \ldots : z_{n-1}) = (J_{1n} : J_{2n} : \ldots : J_{n-1,n}). \]

Since for small \( Z \) its components approximate the angular velocities \( \omega_{1n}, \ldots, \omega_{n-1,n} \) of the continuous multidimensional system (4.12), the line \( \mathbb{P} \) approximates line (4.14) of equilibrium points in so(n).

**Theorem 6.4.** The generalized Euler–Poincaré–Suslov dynamics has the following properties:

(i) The multi-valued map \( B \) preserves the reduced constrained energy
\[ \frac{1}{2} \langle M, \Lambda^{-1}M \rangle, \] (6.22)
which, after using (6.20) and multiplying by \( 2 \det \Lambda \), yields the quartic conservation law
\[ H = \langle Z, \Lambda Z \rangle (\langle Z, J \rangle^2 + z_0^2 \det \Lambda). \] (6.23)

(ii) Regardless of which branch of the map \( B \) is chosen, the discrete dynamics evolves from unstable equilibria on \( \ell \cap \{ \langle J, M \rangle < 0 \} \) towards stable equilibria on \( \ell \cap \{ \langle J, M \rangle > 0 \} \).

**Proof.** (i) Substituting formulae (6.20) and (6.21) into (6.22) produces identical results in terms of \( z \)-variables. Transforming this expression into the form (6.23) is a pure calculation.

(ii) Using (6.21), we obtain
\[ \langle J, M_{k+1} \rangle = \langle J, M_k \rangle + 4 \sum_{1 < i < j < n} (Z_k \wedge J)^2_{ij}. \]

Hence, the quantity \( \langle J, M \rangle \) increases unless \( M \) belongs to the equilibrium set \( \ell \). \( \square \)

### 7. The discrete Chaplygin sleigh

In this section we study the discrete Euler–Poincare–Suslov equation (3.10) on the dual Lie algebra se^*(2). See [8] for an elementary exposition of this problem.

**The discrete Lagrangian.** Recall that the angular orientation and position of the contact point of the sleigh are \( \theta \) and \( (x, y) \), respectively. The two subsequent positions of the sleigh are given by the matrices
\[ g_k = \begin{pmatrix} \cos \theta_k & -\sin \theta_k & x_k \\ \sin \theta_k & \cos \theta_k & y_k \\ 0 & 0 & 1 \end{pmatrix}, \quad g_{k+1} = \begin{pmatrix} \cos \theta_{k+1} & -\sin \theta_{k+1} & x_{k+1} \\ \sin \theta_{k+1} & \cos \theta_{k+1} & y_{k+1} \\ 0 & 0 & 1 \end{pmatrix}. \]

The incremental displacement \( W_k = g_k^{-1}g_{k+1} \in SE(2) \) is computed to be
\[ W_k = \begin{pmatrix} \cos \Delta \theta_k & -\sin \Delta \theta_k & \cos \theta_k \Delta x_k + \sin \theta_k \Delta y_k \\ \sin \Delta \theta_k & \cos \Delta \theta_k & -\sin \theta_k \Delta x_k + \cos \theta_k \Delta y_k \\ 0 & 0 & 1 \end{pmatrix}, \] (7.1)

where \( \Delta \theta_k = \theta_{k+1} - \theta_k \), \( \Delta x_k = x_{k+1} - x_k \) and \( \Delta y_k = y_{k+1} - y_k \).
Following the general formula (3.1), we compute the left-invariant discrete Lagrangian on $SE(2) \times SE(2)$ by replacing the velocity operator with $g_k^{-1}(g_{k+1} - g_k)$ in (5.8). Up to an additive constant, we obtain

$$L_d(g_{k+1}, g_k) = \frac{1}{2} \text{Tr}(W_k W_k^T) - \frac{1}{2} \text{Tr}(J W_k^T + W_k J),$$

(7.2)

where

$$J = \begin{pmatrix}
\frac{J}{2} + ma^2 & mab & ma \\
mab & \frac{J}{2} + mb^2 & mb \\
ma & mb & m
\end{pmatrix}.$$

Recall that $J$ is the moment of inertia of the body relative to its centre of mass, $m$ is the mass and $(a, b)$ are the coordinates of the centre of mass of the body measured from the contact point in the directions along and orthogonal to the blade. Evaluating (7.2), we obtain

$$L_d = (J + ma^2 + mb^2)(1 - \cos \Delta \theta_k) + \frac{m}{2} \Delta x_k^2 + \frac{m}{2} \Delta y_k^2$$

$$+ am[(\cos \theta_{k+1} - \cos \theta_k)\Delta x_k + (\sin \theta_{k+1} - \sin \theta_k)\Delta y_k]$$

$$+ bm[-(\sin \theta_{k+1} - \sin \theta_k)\Delta x_k + (\cos \theta_{k+1} - \cos \theta_k)\Delta y_k].$$

(7.3)

Observe that setting

$$\sin \theta_{k+1} - \sin \theta_k = -h \omega \sin \theta + O(h^2),$$

$$\cos \theta_{k+1} - \cos \theta_k = h \omega \cos \theta + O(h^2),$$

(7.4)

and computing the limit

$$\lim_{h \to 0} \frac{L_d}{h^2}$$

produces the continuous-time Lagrangian of the Chaplygin sleigh (5.1).

According to definition (3.2), the components of the discrete momentum relative to the body frame, $p_k = (M_k, \Pi_1,k, \Pi_2,k) \in se^*(2)$, are

$$M_k = -\left. \frac{\partial}{\partial s} \right|_{s=0} L_d(\theta_k + s, \theta_{k+1}, x_k, x_{k+1}, y_k, y_{k+1}),$$

$$\Pi_{1,k} = -\left. \frac{\partial}{\partial s} \right|_{s=0} L_d(\theta_k, \theta_{k+1}, x_k + s \cos \theta_k, x_{k+1}, y_k + s \sin \theta_k, y_{k+1}),$$

$$\Pi_{2,k} = -\left. \frac{\partial}{\partial s} \right|_{s=0} L_d(\theta_k, \theta_{k+1}, x_k - s \sin \theta_k, x_{k+1}, y_k + s \cos \theta_k, y_{k+1}),$$

that is,

$$M_k = (J + ma^2 + mb^2) \sin \Delta \theta_k + amV_{2,k} - bmV_{1,k},$$

$$\Pi_{1,k} = mV_{1,k} - am(1 - \cos \Delta \theta_k) - bm \sin \Delta \theta_k,$$

$$\Pi_{2,k} = mV_{2,k} + am \sin \Delta \theta_k - bm(1 - \cos \Delta \theta_k),$$

(7.5)

where

$$V_{1,k} = \Delta x_k \cos \theta_k + \Delta y_k \sin \theta_k,$$

$$V_{2,k} = -\Delta x_k \sin \theta_k + \Delta y_k \cos \theta_k$$

(7.6)

are the components of the ‘discrete velocity’ of the centre of mass, relative to the body frame.

In the absence of constraints the dynamics of the two-dimensional body is represented by the discrete Euler–Poincaré equations

$$p_{k+1} = Ad^*_{W_k} p_k,$$

(7.7)
where
\[
\text{Ad}_{W_k}^p = \begin{pmatrix}
M_k - \Pi_{2,k} V_{1,k} + \Pi_{1,k} V_{2,k} \\
\Pi_{1,k} \cos \Delta \theta_k + \Pi_{2,k} \sin \Delta \theta_k \\
- \Pi_{1,k} \sin \Delta \theta_k + \Pi_{2,k} \cos \Delta \theta_k
\end{pmatrix}.
\] (7.8)

Equation (7.7) is just the momentum conservation law written in the body frame. In particular, if the centre of mass is at the contact point, that is \(a = b = 0\), (7.7) becomes
\[
\sin \Delta \theta_k = \sin \Delta \theta_{k-1},
\Delta x_{k+1} \cos \theta_{k+1} + \Delta y_{k+1} \sin \theta_{k+1} = \Delta x_k \cos \theta_{k+1} + \Delta y_k \sin \theta_{k+1},
-\Delta x_{k+1} \sin \theta_{k+1} + \Delta y_{k+1} \cos \theta_{k+1} = -\Delta x_k \sin \theta_{k+1} + \Delta y_k \cos \theta_{k+1}.
\]

If \(\Delta \theta\) is sufficiently small, the above formulae imply that the increments \(\theta_{k+1} - \theta_k, x_{k+1} - x_k\) and \(y_{k+1} - y_k\) are the same for any integer \(k\), the result one expects from studying the continuous problem.

The discrete constraint on \(SE(2)\). We now impose a discrete left-invariant constraint on \(SE(2)\) in the form of restrictions on the incremental displacements \(W_k = g_k^{-1} g_{k+1}\).

A tempting choice of a discrete constraint that mimics the non-slip condition (5.2) is
\[
V_2, k = -\sin \theta_k \Delta x_k + \cos \theta_k \Delta y_k = 0.
\] (7.9)

This choice, however, is not the right one. Indeed, following our general approach (3.4), constrained incremental displacements are the exponents of the matrices of the form (5.11). In this case, \(h\) generates the subgroup \(SE(n-1)\) and, according to proposition 3.1, \(\exp d\) covers the homogeneous space \(SE(n) / SE(n-1)\). For a matrix \(W \in SE(n)\), we write its components as \(W_{ij}\). In the case \(n = 2\), when \(W_k\) is given by (7.1), we have the following.

**Theorem 7.1.** The variety \(S = \exp d \subset SE(2)\) is diffeomorphic to the canonical line bundle \(\pi : \mathbb{M} \to \mathbb{R} P^1 = \{(z_1 : z_2)\} \) such that \(\pi^{-1}(z_1 : z_2)\) is a line \(\{(\tau z_1, \tau z_2) | \tau \in \mathbb{R}\} \subset \mathbb{R}^2\) (i.e. \(\mathbb{M}\) is an unbounded Möbius strip). Analytically, \(S\) is represented by the equation
\[
W_{23} W_{13} = \frac{1 - W_{11}}{W_{21}},
\] (7.10)
which defines the discrete constraint
\[
- (\Delta x_k \cos \theta_k + \Delta y_k \sin \theta_k) \sin \left(\frac{\Delta \theta_k}{2}\right) + (- \Delta x_k \sin \theta_k + \Delta y_k \cos \theta_k) \cos \left(\frac{\Delta \theta_k}{2}\right) = 0
\] (7.11)
or, equivalently,
\[
V_{1,k} (1 - \cos \Delta \theta_k) - V_{2,k} \sin \Delta \theta_k = 0.
\] (7.12)

**Proof.** For an element
\[
\xi = \begin{pmatrix} 0 & -\omega & \nu \\ \omega & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \in d
\]
we have
\[
W = \exp \xi = \begin{pmatrix} \cos \omega & -\sin \omega & \frac{\nu}{\omega} \sin \omega \\ \sin \omega & \cos \omega & \frac{\nu}{\omega} (1 - \cos \omega) \\ 0 & 0 & 1 \end{pmatrix},
\]
where $\omega$ and $v$ are arbitrary. As a result, (7.10) holds for $W_k \in S$. Next, for $\omega = \Delta \theta_k$ we obtain
\[
\frac{W_{23}}{W_{13}} = \frac{1 - \cos \omega}{\sin \omega} = \tan \frac{\Delta \theta_k}{2},
\] (7.13)
which implies (7.11) and (7.12).

Finally, formula (7.13) represents the slope of the line $W_{23}x - W_{13}y = 0$ in the plane $\mathbb{R}^2$. As $\Delta \theta_k$ increases from 0 to $2\pi$, this line rotates by the angle $\pi$. Hence, $S$ is diffeomorphic to the Möbius strip. □

**Corollary 7.2.** The discrete left-invariant Chaplygin constraint on $SE(2) \times SE(2)$ reads
\[
F = -\sin \left(\frac{\theta_{k+1} + \theta_k}{2}\right) \Delta x_k + \cos \left(\frac{\theta_{k+1} + \theta_k}{2}\right) \Delta y_k = 0.
\] (7.14)
The limit $\lim_{h \to 0} F/h$, with $\Delta \theta_k$, $\Delta x_k$ and $\Delta y_k$ defined as in (7.4), equals the continuous-time Chaplygin constraint (5.2).

**Remark.** As seen from (7.11), the matrices from $S \subset SE(2)$ represent ‘circular displacements’ of the sleigh: the points $(x_k, y_k)$ and $(x_{k+1}, y_{k+1})$ in $\mathbb{R}^2$ belong to a circle, with the blade directions at these points tangent to the same circle. This property also implies
\[
\Delta x_k \cos \theta_k + \Delta y_k \sin \theta_k = \Delta x_k \cos \theta_{k+1} + \Delta y_k \sin \theta_{k+1},
\]
\[
-\Delta x_k \sin \theta_k + \Delta y_k \cos \theta_k = \Delta x_k \sin \theta_{k+1} - \Delta y_k \cos \theta_{k+1},
\] (7.15)
see figure 5.

The discrete Chaplygin constraint (7.11) has also the following interpretation: in order to transfer the sleigh from $(\theta_k, x_k, y_k) \in SE(2)$ to $(\theta_{k+1}, x_{k+1}, y_{k+1}) \in SE(2)$ (assuming that this transition is possible), one needs first to perform the rotation by $\Delta \theta_k/2$ at $(x_k, y_k)$, which aims the sleigh towards $(x_{k+1}, y_{k+1})$, then slide the sleigh from $(x_k, y_k)$ to $(x_{k+1}, y_{k+1})$, and thereafter perform additional rotation by $\Delta \theta_k/2$ at $(x_{k+1}, y_{k+1})$.

The discrete momentum locus $U \subset se^*(2)$. One can show that in the presence of constraint (7.12) the image of the discrete Legendre transform (7.5) is an algebraic quartic
subvariety $\tilde{\mathcal{U}} \subset se^*(2) = \{(M, \Pi_1, \Pi_2)\}$ and that there are four inverse images of a generic point $(M, \Pi_1)$ in $S \subset SE(2)$. Here we concentrate on the important case $b = 0$, when the structure of the real surface $\mathcal{U} \subset se^*(2)$ becomes simpler. It is more convenient to study the image $\tilde{\mathcal{U}}$ of the surface $\mathcal{U}$ in $\mathbb{R}^3$ parametrized by the coordinates $(M, Y, Z)$, where

$$Y = a\Pi_1 + 2ma^2,$$

$$Z = \sin \Delta_1 \theta.$$

**Lemma 7.3.** Let $b = 0$. Then:

(i) The surface $\tilde{\mathcal{U}}$ is given by the cubic polynomial equation

$$J^2Z^3 - 2JMZ^2 + (Y^2 + 2JY + M^2)Z - 2MY = 0 \quad (7.16)$$

and lies between and is tangent to the planes $Z = \pm 1$ along the lines $\ell_{\pm} = \{\pm M - Y = J\}$. The $M$ and $Y$ axes belong entirely to $\tilde{\mathcal{U}}$.

(ii) For the parts of $\tilde{\mathcal{U}}$ over the quadrants $\{-Y + M > J\} \cap \{-Y - M > J\}$ and $\{-Y + M < J\} \cap \{-Y - M < J\}$ the quantity $\cos \Delta \theta$ is positive, i.e. $-\pi/2 < \Delta \theta < \pi/2$, and in the rest of the quadrants $\cos \Delta \theta$ is negative, i.e. $\pi/2 < \Delta \theta < 3\pi/2$.

(iii) The projection $\tilde{\pi} : \tilde{\mathcal{U}} \to \mathbb{R}^2 = \{(M, Y)\}$ is one-to-one everywhere but in the interior of the triangular region bounded by the discriminant curve

$$Y^4 + 6JY^3 + Y^2(12J^2 + 2M^2) - Y(10JM^2 - 8J^3) + M^4 - J^2M^2 = 0,$$

which is symmetric with respect to the $Y$-axis, is tangent to the $M$-axis at the origin $(0, 0)$, and has three cusp points. Within the region bounded by this curve the projection $\tilde{\pi}$ is three-to-one.

(iv) Let $\tilde{\mathcal{V}}$ be a subset of $\tilde{\mathcal{U}}$ defined by the condition $V_1 = 0$. Its projection onto the $MY$-plane is the ellipse

$$E = \{(M = (J + ma^2) \sin \Delta \theta, Y = ma^2(1 + \cos \Delta \theta) \mid \Delta \theta \in (0, 2\pi))\}. \quad (7.17)$$

The points of $\tilde{\mathcal{U}}$ with $V_1 < 0 (V_1 > 0)$ are projected inside (outside) the ellipse $E$.

Note that the point $(M, Y) = (0, 2ma^2)$ corresponds to the origin in the $M\Pi_1$-plane and that the projection $\tilde{\pi}$ is one-to-one in a neighbourhood of this point. An example of the surface $\tilde{\mathcal{U}}$ and its projection onto the $MY$-plane for $J = 1.5, m = 0.3$ and $a = 1$ is presented in figure 6. The shaded region in figure 6, right, represents the set where the projection $\tilde{\pi}$ is three-to-one.

**Figure 6.** The surface $\tilde{\mathcal{U}}$ and its projection onto the $MY$-plane.
Proof. (i) Using condition (7.12), we eliminate $\Pi_1$ and $\Pi_2$ from the first two equations of system (7.5) and obtain the following equation for $\Delta \theta_k$:

$$J \sin^2 \Delta \theta_k - M_k \sin \Delta \theta_k + (2ma^2 + a\Pi_{1,k})(1 - \cos \Delta \theta_k) = 0. \quad (7.18)$$

This equation always has trivial solutions $\Delta \theta_k = 2n\pi$, $n \in \mathbb{Z}$. Setting $\sin \Delta \theta_k = Z$, $\cos \Delta \theta_k = \sqrt{1 - Z^2}$ and $Y = a\Pi_1 + 2ma^2$, we arrive at a quartic polynomial equation with respect to $Z$, which has the root $Z = 0$. Factoring out $Z$ and omitting the index $k$, one obtains the cubic equation (7.16). By setting $z = \pm 1$ in (7.16) we obtain $(J + M + Y)^2 = 0$, which implies that $\mathcal{U}$ is, indeed, tangent to the planes $Z = \pm 1$ along the lines $\ell_{\pm}$. Finally, setting $Z = M = 0$ or $Z = Y = 0$, one sees that equation (7.16) becomes an identity for arbitrary $Y$ and $M$, respectively.

(ii) For a fixed $(M, \Pi_1)$, each root of (7.16) gives a solution of (7.18), with the sign of $\cos \Delta \theta_k$ appropriately chosen. As seen from (7.18), for $|\Pi_1|$ large and $z = \sin \Delta \theta$ small the value of $\cos \Delta \theta$ is close to 1, whereas for $M$ positive and large and $|\Pi_1|$ small the value of $\cos \Delta \theta$ is negative. The sign of $\cos \Delta \theta$ can change only when a point in the $\mathbb{M}\Pi_1$-plane moves from one quadrant to another. This finishes the proof of part (ii).

Parts (iii) and (iv) are verified by straightforward calculations. □

The discrete constrained dynamics on $se^*(2)$. According to (3.10), the discrete Euler–Poincaré–Suslov equations for the Chaplygin sleigh read

$$p_{k+1} = \text{Ad}_{\Pi_1, k}^* p_k + \lambda_k(0, 0, 1) \quad (7.19)$$

with $\text{Ad}_{\Pi_1, k}^* p_k$ given by formula (7.8). Eliminating the Lagrange multiplier $\lambda_k$ from (7.19), we obtain

$$M_{k+1} = (J + ma^2 + mb^2) \sin \Delta \theta_k - bm V_{1,k} + am[-\Delta x_k \sin \theta_{k+1} + \Delta y_k \cos \theta_{k+1}],$$

$$\Pi_{1,k+1} = m V_{1,k} - bm \sin \Delta \theta_k + am[\Delta x_k \cos \theta_{k+1} + \Delta y_k \sin \theta_{k+1}],$$

which when (7.15) and (7.5) are taken into account, yield

$$M_{k+1} = M_k - 2am V_{2,k}, \quad \Pi_{1,k+1} = \Pi_{1,k} + 2am(1 - \cos \Delta \theta_k). \quad (7.20)$$

Formulae (7.20) and (7.12) define multi-valued maps $\mathcal{U} \to \mathcal{U}$ and $\mathcal{S} \to \mathcal{S}$. These maps are evaluated as follows:

1. Given $\Delta \theta_k$ and $V_{1,k}$, one finds $V_{2,k}$ from constraint (7.12) and then computes $(M_k, \Pi_{1,k}, \Pi_{2,k})$ as an output of the Legendre transform (7.5).
2. Next, one finds $M_{k+1}$ and $\Pi_{1,k+1}$ from (7.20).
3. Finally, one finds $\Delta \theta_{k+1}$ and $V_{1,k+1}$ by solving the system of equations

$$M_{k+1} = (J + ma^2 + mb^2) \sin \Delta \theta_{k+1} + \left(\frac{am(1 - \cos \Delta \theta_{k+1}) - bm}{\sin \Delta \theta_{k+1}}\right) V_{1,k+1},$$

$$\Pi_{1,k+1} = m V_{1,k+1} - am(1 - \cos \Delta \theta_{k+1}) - bm \sin \Delta \theta_{k+1}$$

obtained from (7.5) and (7.12) by replacing $k$ with $k + 1$.

Theorem 7.4. Equations (7.20) preserve the reduced constrained energy of the continuous-time Chaplygin sleigh

$$E_c(M, \Pi_1) = \frac{mM^2 + 2bmM\Pi_1 + (J + m(a^2 + b^2))\Pi_1^2}{m(J + ma^2)}. \quad (7.21)$$
Proof. Evaluating $E_c(M_{k+1}, \Pi_{1,k+1})$ and $E_c(M_k, \Pi_{1,k})$ while taking into account equations (7.5), (7.20) and constraint (7.12), one recovers identical expressions in terms of $\Delta \theta_k, V_{1,k}$ and $V_{2,k}$.

Since the quadratic form (7.21) is positive-definite, the invariant manifolds of map (7.20) are the ellipses in the $M\Pi_1$-plane.

The relative equilibria of the discrete Chaplygin sleigh. As follows from (7.20), the initial conditions $\{\Delta \theta_k = 0, V_{2,k} = 0\}$ imply $M_{k+1} = M_k$ and $\Pi_{1,k+1} = \Pi_{1,k}$. Hence, it is natural to choose such $\lambda_k$ in (7.19) that $\Pi_{2,k+1} = \Pi_{2,k}$ as well. Thus, similar to the continuous system (5.3), for $a \neq 0$ the map (7.19) has a family of equilibria. These equilibria are situated on the line $\{M + b\Pi_1 = 0\}$ in the $M\Pi_1$-plane and correspond to the translations of the contact point in the $xy$-plane along the direction of the blade by constant increments.

On the other hand, for $a = 0$ every solution of (5.3) is an equilibrium. That is, contrary to the unconstrained case, the components of momentum relative to the body frame, rather than the spatial components, are preserved. Equations (7.5) in this case imply $\Delta \theta_{k+1} = \Delta \theta_k, V_{1,k+1} = V_{1,k}$ and hence the discrete trajectories of the contact point in the $xy$-plane are either straight lines or circles. In the latter case, the radius equals $V_{1,k}/\sin(\Delta \theta_k)$. The same behaviour occurs in the continuous-time, balanced $(a = 0)$ sleigh\(^{12}\).

The unbalanced case. In this case $a \neq 0$, and we set $b = 0$ for simplicity. Then the map $(M_k, \Pi_{1,k}) \mapsto (M_{k+1}, \Pi_{1,k+1})$ has a line of equilibria $M = 0$ and, by theorem 7.4, the non-equilibrium discrete trajectories lie on the invariant ellipses $mM^2 + (J + ma^2)\Pi_1^2 = \text{const}$. Without loss of generality, we assume $a > 0$. Then the following property holds.

Theorem 7.5. The map $(M_k, \Pi_{1,k}) \mapsto (M_{k+1}, \Pi_{1,k+1})$ is single-valued in the elliptic neighbourhood of the origin of the $M\Pi_1$-plane given by the condition

$$mM^2 + (J + ma^2)\Pi_1^2 < m^2a^2(J + ma^2).$$  \hspace{1cm} (7.22)

The orbits of this map form heteroclinic connections between the pairs of unstable and stable equilibria similar to that of the continuous-time Chaplygin sleigh. That is, the sequence $\{(M_k, \Pi_{1,k})\}$ approaches a stable (unstable) equilibrium along the corresponding invariant ellipse as $k \to \infty$ ($k \to -\infty$). In both cases the sequence $\{(M_k, \Pi_{1,k})\}$ remains in one of the half-planes $M < 0$ or $M > 0$.

Proof. Part (iii) of lemma 7.3 implies that the map is single-valued in the region (7.22). Next, as follows from the first formula in (7.20) for $a > 0$, the increment $\Pi_{1,k+1} - \Pi_{1,k}$ is always greater than or equal to zero. Thus, to prove the asymptotic behaviour one only needs to show that the sequence $\{(M_k, \Pi_{1,k})\}$ lies entirely in one of the half-planes $M < 0$ or $M > 0$. Indeed, assume first that the point $(M_k, \Pi_{1,k})$ from the neighbourhood (7.22) also lies inside the ellipse $E$ in (7.17) and that $M_k > 0$. Then equation (7.11) and parts (ii) and (iv) of lemma 7.3 imply that $V_{1,k}$ and $V_{2,k}$ are negative. According to (7.20), the increment $M_{k+1} - M_k$ is then positive. Similarly, for $M_k < 0$ one has $M_{k+1} - M_k < 0$. Hence, in this case $M_k$ and $M_{k+1}$ have the same sign.

Next, using (7.5) and (7.11), if the point $(M_k, \Pi_{1,k})$ lies in the region (7.22) but outside the ellipse $E$, then $2amV_{2,k} > M_k$ for $M_k > 0$ and $2amV_{2,k} < M_k$ for $M_k < 0$. Invoking (7.20), $M_k$ and $M_{k+1}$ again have the same sign, which completes the proof.  \hspace{1cm} $\Box$

Observe that the discrete-time momentum dynamics of the Chaplygin sleigh in the neighbourhood of the origin is similar to that of the Suslov problem, illustrated in figure 4.

\(^{12}\) Numerical simulations show that the choice of the ‘naive’ constraint (7.9) instead of (7.10) in the case $a = 0$ results in spiralling discrete trajectories in the $xy$-plane.
We conclude this section with an example of the discrete sleigh trajectory in the $xy$-plane. The dots in figure 7 represent the generic discrete trajectory of the contact point in this plane, whereas the continuous-time trajectory is the solid curve. The discrete dynamics captures the qualitative behaviour of the continuous-time Chaplygin sleigh. In particular, the discrete trajectory has a cusp and asymptotically approaches the straight line motions as $k \to \pm \infty$.

8. Conclusion

The discrete nonholonomic Suslov problem and the discrete Chaplygin sleigh that we introduced in this paper remarkably inherit all of the main properties of their corresponding continuous-time dynamical systems. In particular, they preserve the reduced constrained energy and, in the balanced case, the momentum. It is not currently clear if this behaviour is due to the low dimension of the systems, or if it is possible to construct completely solvable discretizations of the Suslov and Chaplygin problems. These issues will be addressed in future publications.

Our approach can be adapted to study discretizations of nonholonomic LR systems on Lie groups. For such systems, the Lagrangian is left-invariant, whereas the constraint distribution is right-invariant. The discrete dynamics of such systems, as well as the existence of their invariant measure, is currently being developed and will be exposed in a future publication.

Acknowledgments

YuNF’s research was partially supported by the Spanish Ministry of Science and Technology grant BFM 2003-09504-C02-02; DVZ’s research was partially supported by NSF grant DMS-0306017.
