Abstract

In this paper we study stochastic control problems with delayed information, that is, the control at time $t$ can depend only on the information observed before time $t-h$ for some delay parameter $h$. Such delay occurs frequently in practice and can be viewed as a special case of partial observation. When the time duration $T$ is smaller than $h$, the problem becomes a deterministic control problem in stochastic setting. While seemingly simple, the problem involves certain time inconsistency issue, and the value function naturally relies on the distribution of the state process and thus is a solution to a nonlinear master equation. Consequently, the optimal state process solves a McKean-Vlasov SDE. In the general case that $T$ is larger than $h$, the master equation becomes path-dependent and the corresponding McKean-Vlasov SDE involves the conditional distribution of the state process. We shall build these connections rigorously, and obtain the existence of classical solution of these nonlinear (path-dependent) master equations in some special cases.

Keywords: Information delay, partial observation, master equation, McKean-Vlasov SDE, functional Itô formula.

1 Introduction

Consider a stochastic control problem:

$$V_0 = \sup_{\alpha \in A} \mathbb{E}\left[ g(X_T^\alpha) + \int_0^T f(t, X_t^\alpha, \alpha_t)dt \right],$$

where $X_t^\alpha = x + \int_0^t b(s, X_s^\alpha, \alpha_s)ds + \int_0^t \sigma(s, X_s^\alpha, \alpha_s)dW_s$, (1.1)

and $A$ is an appropriate set of $A$-valued admissible controls. It is well known that, under mild conditions, $V_0 = u(0, x)$, where $u$ is the solution of an HJB equation. One standard but crucial condition in the literature is that the admissible control is $\mathbb{F}$-progressively measurable, where $\mathbb{F} = \{\mathcal{F}_t\}_{0 \leq t \leq T}$ is a filtration under which $W$ is a Brownian motion.

Our paper is mainly motivated by the following practical consideration. Note that $\mathcal{F}_t$ stands for the information the player observes over time period $[0, t]$. In many practical situations, the player needs some time to collect and/or to analyze the information, including numerical computations. Thus, the control $\alpha_t$ the player needs to act at time $t$ may not be able to utilize the most recent information, or say, there is some information delay. To be precise, let $h > 0$ be a fixed constant standing for the delay

parameter. In this paper we shall study the control problem (1.1) by restricting the admissible control $\alpha$ in $A^0_0$, i.e. such that $\alpha_t \in F_{t-\omega}$, for all $t \in [0, T]$. This can be viewed as a special case of stochastic controls with partial observation. For a literature review, see Section 1.1.

We first consider the simple case that $T \leq \infty$. Then $\alpha_t \in L^0(F_0)$ for all $t \in [0, T]$, and thus this is a deterministic control problem (assuming $F_0$ is degenerate), but in a stochastic framework. While seemingly simpler, the constraint that the control is deterministic actually makes the problem more involving. The main reason is that such a problem is time inconsistent if one follows the standard seemingly simpler, the constraint that the control is deterministic actually makes the problem more involving.

When one considers a dynamic problem over time period $[0, T]$, will become $\tilde{\alpha}$, and thus typically $\tilde{\alpha} = \tilde{\alpha}(t, x)$ should typically depend only on the initial value $x$ for all $t \in [0, T]$. When one considers a dynamic problem over time period $[t_0, T]$, the new “deterministic” optimal control will become $\tilde{\alpha} = \alpha^* (t, X_t^*)$ for all $t \in [t_0, T]$, which will be $F_{t_0}$-measurable rather than $F_0$-measurable, and thus typically $\tilde{\alpha}^* \neq \alpha^*$ for $t \geq t_0$. That is, the problem is time inconsistent.

We aim to solve the problem in a time consistent way. Note again that, in standard control problem, the optimal control reacts to the state process $X^*_t$ and thus typically $\tilde{\alpha}^* = \alpha^*(t, X^*_t)$ for all $t \in [0, T]$, which will be $F_0$-measurable, and the function $V$ satisfies an appropriate dynamic programming principle and is the solution of a so-called master equation. Moreover, $V_0 = V(0, \delta_x)$, where $x$ is the initial value $X_{t_0}$ and $\delta_x$ is the Dirac-measure of $x$.

To understand the master equation, we remark that $V : [0, T] \times P_2(\mathbb{R}^d) \rightarrow \mathbb{R}$ is a deterministic function, where $P_2(\mathbb{R}^d)$ is the set of square-integrable probability measures on $\mathbb{R}^d$. It is known that the derivative of $V$ in terms of $\mu \in P_2(\mathbb{R}^d)$ takes the form $\frac{\partial V}{\partial \mu}(t, x) \in [0, T] \times P_2(\mathbb{R}^d) \times \mathbb{R}^d \rightarrow \mathbb{R}^d$. Denote by $\frac{\partial V}{\partial \mu}$ the standard derivative of $V$ with respect to $x$. Then the optimization problem (1.1) with deterministic control is associated with the following HJB type of master equation:

$$\frac{\partial V}{\partial t}(t, \mu) + H(t, \mu, \frac{\partial V}{\partial \mu}, \frac{\partial^2 V}{\partial \mu^2}) = 0, \quad V(T, \mu) = \mathbb{E}[g(\xi)],$$

where, for $p : [0, T] \times P_2(\mathbb{R}^d) \times \mathbb{R}^d \rightarrow \mathbb{R}$ and $q : [0, T] \times P_2(\mathbb{R}^d) \times \mathbb{R}^d \rightarrow \mathbb{R}^{d \times d}$, $H(t, \mu, p, q) := \sup_{a \in A} h(t, \mu, p, q, a)$,

$$h(t, \mu, p, q, a) := \mathbb{E}\left[ b(t, \xi, a) \cdot p(t, \mu, \xi) + \frac{1}{2} \sigma^T(t, \xi, a) \cdot q(t, \mu, \xi) + f(t, \xi, a) \right].$$

Here $\xi$ is a random variable with law $\mu$. We shall prove the existence of classical solutions for a special case of (1.2), which to our best knowledge is new in the literature.

Assume further that the Hamiltonian $H$ has optimal argument $a^* = I(t, \mu)$ for some function $I : [0, T] \times P_2(\mathbb{R}^d) \rightarrow A$, then the optimal control is $\alpha^* = I(t, \mathcal{L}_\xi)$, where $\mathcal{L}_\xi$ is the law of the random variable $\xi$ and $X^*$ solves the following McKean-Vlasov SDE (assuming its wellposedness):

$$X_t^* = x + \int_0^t b(s, X_s^*, I(s, \mathcal{L}_\xi)) \, ds + \int_0^t \sigma(s, X_s^*, I(s, \mathcal{L}_\xi)) \, dW_s.$$  

We shall carry out the verification theorem rigorously when $I$ is continuous.

We finally consider the general case $T > \infty$. In this case, for $t > \infty$, the control $\alpha_t$ is required to be $F_{t-w}$-measurable. Motivated by both theoretical and practical considerations, we shall use closed-loop controls, namely $\alpha_t = \alpha_t(X_{[0,t-w]})$ is $F_{t-w}$-measurable. Then the value function, $V(t, \mu_{[0,t]})$, will be path-dependent in the sense that $\mu_{[0,t]}$ denotes the law of the stopped process $X_{[0,t]}$, and the master equation (1.2) becomes a path-dependent equation. Consequently, the McKean-Vlasov SDE (1.4) will involve the conditional law of $X^*_t$.

We finish this section with a thoroughly comparison of different problems and methods that relates to the ones proposed here, which is further developed in Appendix B. The rest of the paper will be organized as follows. We discuss the deterministic case in Section 2. Moreover, a special case is fully developed in Section 3 and the general theory is presented in Section 4.
1.1 Comparison to Similar Control Problems and Methods

As mentioned above, problem (1.1) with $\alpha \in A^0_h$ might be seen as a special case of stochastic controls with partial observation. Generally, these stochastic control problems assume that the admissible controls are adapted to a smaller filtration $\mathcal{G}$, i.e. $\mathcal{G}_t \subset \mathcal{F}_t$, for all $t \in [0,T]$. Few papers have tackled this problem under this generality, see, for instance, Christopeit [1980], where the existence of the optimal control is studied, and Baghery and Øksendal [2007], where a maximum principle was derived under the more general Lévy processes.

Additionally to the delayed case studied in our paper, a very important example of the partial observation problem is the case of noisy observation. This situation has drawn significantly more attention than the other types of partially observed systems. For references, see Bensoussan [1992], Fleming and Pardoux [1982], Fleming [1980, 1982], Bismut [1982], Tang [1998], and the more recent Bandini et al. [2016a,b]. On these aforesaid references, a separated control problem is proposed and studied. The optimal control problem of the partially observed system is connected to this separated problem, which is completely observed, using stochastic nonlinear filtering. It is worth noticing that, similarly to what we have found in the control with delayed information, the state variable of the separated control problem is an unnormalized conditional distribution measure and the class of admissible controls is a set of probability measures. Moreover, the dynamics of the aforementioned unnormalized conditional distribution measure is given by the so-called Zakai’s equation.

Moreover, in Bandini et al. [2016b], the authors have derived, in this context of noisy observation, the dynamic programming principle with flow of probability measures as state variable and the verification theorem of their master equation. Since the deterministic control problem studied in Section 2 is a particular case of the noisy observation problem, our master equation and the dynamic programming principle in this section could be seen as a special case of theirs. However, our arguments here are much simpler, due to our special setting, and will be important for the general case in Section 4, so we decide to report our proofs in details so that the readers can easily grasp the main ideas.

In a different direction, although analyzing the same control problem as in the references in the paragraph above, Mortensen [1966] and Beneš and Karatzas [1983] have studied the value of the control problem as a function of the initial conditional probability density and an HJB equation analogous to our master equation (1.2) was derived. Moreover, an Itô formula for functions of density-valued processes was proved, c.f. Lemma 2.7. Under the assumption that the agent observes pure independent noise, it turns out that their control problem is equivalent to our deterministic control problem in Section 2. Moreover, when restricting to only those measures with density, our master equation (1.2) is equivalent to Mortensen’s HJB equation. In order to verify this, one needs to understand the relation between Gâteaux derivatives with respect to the probability densities and $\partial \mu V$, see Bensoussan et al. [2017]. For more details, see Appendix B.

Furthermore, in the direction of applications of the delayed information setting to Mathematical Finance, Ichiba and Mousavi [2017] have proposed a discrete-time binomial model with delayed information for the price of asset. They studied the super-replication of derivatives with convex payoffs and also the convergence of their model to a continuous-time one (without delay).

A different aspect of delay in control problems is when the control chosen in a previous time, for instance at $t - h$, influences the dynamics and/or the cost function at time $t$. In the literature, this is usually called stochastic controls problems with delay in the control, see for example, Gozzi and Marinelli [2006], Gozzi and Masiero [2015], Alekal et al. [1971], Chen and Wu [2011]. More generally, path dependence in the control was studied in Saporito [2017] in the framework of functional Itô calculus. This type of delay in the control is fundamentally different than the one we study here. Notice that, although the control acts with delay, the agent has full information at time $t$ to choose $\alpha_t$. This deparls completely from the setting we are proposing in this paper. Moreover, as one could easily notice from the aforesaid references, the value function $V$ are not seen as function of probability measures, but a function of the history of the state process. This type of delay in the control was recently applied to the study of systemic risk of a system of banks in Carmona et al. [2016].

We remark that the McKean-Vlasov SDE (for forward state process) and the master equation (for
backward value function) have received very strong attention in recent years, mainly due to its application in mean field games and systemic risk, see Caines et al. [2006], Larys and Lions [2007], as well as Cardaliaguet [2013], Bensoussan et al. [2013], Carmona and Delarue [2017a,b], and the references therein. In those applications, a large number of players are involved and the measure \( \mu \) is introduced to characterize the aggregate behavior of the players. Our motivation here is quite different. We also remark that our paper deals with control problems and the master equation is nonlinear in \( \partial_\mu V \) (and/or \( \partial_x \partial_\mu V \)). For mean field game problems, the master equation involves \( V(t, x, \mu) \) and has quite different nature. On one hand those master equations are nonlocal, and on the other hand they are typically nonlinear in \( \partial_x V \) but linear in \( \partial_\mu V \). In fact, in some literature master equations refer to only those for mean field games while the equations for control problems are called HJB equations in Wasserstein space. We nevertheless call both master equations since they share many features. In a special case, we will prove the existence of classical solutions for the nonlinear master equation (1.2). In general it is difficult to obtain classical solutions for master equations, some positive results include Buckdahn et al. [2017], Cardaliaguet et al. [2015], and Chassagneux et al. [2015] where the equations are linear in \( \partial_\mu V \) and \( \partial_x \partial_\mu V \), and Gangbo and Swiech [2015] and Bensoussan and Yam [2018] where the equations are of first order (without involving \( \partial_x \partial_\mu V \)). We also refer to Pham and Wei [2015] and Wu and Zhang [2018] for viscosity solutions of master equations.

Furthermore, although we are considering control problems, the delayed observation aspect of our setting is present in Bensoussan et al. [2015] and Bensoussan et al. [2017] which study Stackelberg stochastic games with delayed information. A simple version of these games can be described by two players: a leader and a follower. The leader has full information of both players’ states and the follower has delayed information of the leader state variable (and full information of himself/herself). In aforesaid references, the authors study the convergence of the system of \( N \)-players to its mean field counterpart. Moreover, in the linear-quadratic case, they were able to analyze and derive exact formulas for the mean field game.

2 The Deterministic Control Problem

We remark that this case is the intersection of several related works. For example, Hu and Tang [2017] studied the linear quadratic case by using the stochastic maximum principle, see Appendix A; Beneš and Karatzas [1983] derived a similar equation when the measures have a density, see Appendix B; in particular, our master equation (2.12)-(2.13) and the DPP Theorem 2.3 below are already covered by Bandini et al. [2016b] as a special case. However, since the arguments here are much simpler due to the special structure, which could be helpful for readers to grasp the main ideas, and more importantly since these arguments will be important for the general case in Section 4, we still provide the details.

Let \( T > 0 \) be a fixed time horizon, \( (\Omega, \mathcal{F}, \mathbb{P}) \) a filtered probability space on \([0, T]\), and \( W \) an \( \mathcal{F} \)-Brownian motion under \( \mathbb{P} \). In this section we assume \( T \leq h \) and thus the controls are deterministic. Denote by \( \mathcal{P}_2(\mathbb{R}^d) \) the set of square-integrable measures on \( \mathbb{R}^d \), and for each \( \mu \in \mathcal{P}_2(\mathbb{R}^d) \), denote \( L^2_\mu(\mathcal{F}_t) := \{ \xi \in L^2(\mathcal{F}_t) : \mathcal{L}_\xi = \mu \} \), where \( \mathcal{L}_\xi \) denotes the law of \( \xi \) and \( L^2(\mathcal{F}_t) \) is the space of \( \mathcal{F}_t \)-measurable square-integrable random variables. For technical convenience, we shall assume \( \mathcal{F}_0 \) is rich enough such that \( L^2_\mu(\mathcal{F}_0) \neq \emptyset \) for all \( \mu \in \mathcal{P}_2(\mathbb{R}^d) \). However, in this and the next section we nevertheless assume the controls are deterministic, rather than \( \mathcal{F}_0 \)-measurable. Finally, denote \( \Theta := [0, T] \times \mathcal{P}_2(\mathbb{R}^d) \) and \( \mathcal{F} := \{(t, \xi) : t \in [0, T], \xi \in L^2(\mathcal{F}_t)\} \).
2.1 The control problem

Let $A$ be an (arbitrary) measurable set in certain Euclidian space, and $\mathcal{A}_t$ the set of all Borel measurable functions $\alpha : [t, T] \rightarrow A$. For any $(t, \xi) \in \Theta$ and $\alpha \in \mathcal{A}_t$, define

$$X^{t, \xi, \alpha}_s = \xi + \int_t^s b(r, X^{r, \xi, \alpha}_r, \alpha_r)dr + \int_t^s \sigma(r, X^{r, \xi, \alpha}_r, \alpha_r)dW_r, \quad s \in [t, T],$$

$$J(t, \xi, \alpha) := \mathbb{E} \left[ g(X^T_T, \alpha_T) + \int_t^T f(s, X^{s, \xi, \alpha}_s, \alpha_s)ds \right],$$

(2.1)

where $b, \sigma, f, g$ are deterministic functions with appropriate dimensions.

**Assumption 2.1** (i) $b, \sigma, f, g$ are measurable in all their variables, and $b(t, 0, a), \sigma(t, 0, a), f(t, 0, a)$ are bounded;
(ii) $b, \sigma$ are uniformly Lipschitz continuous in $x$, and uniformly continuous in $t$;
(iii) $f$ is uniformly continuous in $(t, x)$, and $g$ is uniformly continuous in $x$.

Under Assumption 2.1, clearly the SDE in (2.1) is wellposed and

$$|J(t, \xi, \alpha)| \leq C[1 + \|\xi\|^2].$$

(2.2)

Moreover, the following result is obvious:

**Lemma 2.2** Under Assumption 2.1, the mapping $\xi \mapsto J(t, \xi, \alpha)$ is law invariant. That is, if $\mathcal{L}_\xi = \mathcal{L}_\xi'$, then $J(t, \xi, \alpha) = J(t, \xi', \alpha)$.

We are now ready to introduce the optimization problem:

$$V(t, \mu) := \sup_{\alpha \in \mathcal{A}_t} J(t, \xi, \alpha), \quad (t, \mu) \in \Theta \text{ and } \xi \in \mathbb{L}^2_\mu(\mathcal{F}_t).$$

(2.3)

By (2.2), $V(t, \mu)$ is finite. We emphasize that $V$ does not depend on the choice of $\xi$, thanks to Lemma 2.2. Throughout this section, when there is no confusion, for a given $(t, \mu) \in \Theta$ we shall always use $\xi$ to denote some random variable in $\mathbb{L}^2_\mu(\mathcal{F}_t)$, and the claimed results will not depend on the choice of $\xi$.

We next establish the dynamic programming principle for $V$.

**Theorem 2.3** Let Assumption 2.1 hold. Then, for any $(t_1, \mu) \in \Theta$, $t_2 \in (t_1, T]$,

$$V(t_1, \mu) = \sup_{\alpha \in \mathcal{A}_{t_1}} \left[ V(t_2, \mathcal{L}_{X^{t_1, \xi, \alpha}_r}) + \int_{t_1}^{t_2} \mathbb{E}[f(s, X^{s, \xi, \alpha}_s, \alpha_s)]ds \right].$$

(2.4)

**Proof.** For notational simplicity, we assume $t_1 = 0$ and $t_2 = t$, then (2.4) becomes:

$$V(0, \mu) = \tilde{V}(0, \mu) := \sup_{\alpha \in \mathcal{A}_0} \left[ V(t, \mathcal{L}_{X^{0, \xi, \alpha}_r}) + \int_0^t \mathbb{E}[f(s, X^{s, \xi, \alpha}_s, \alpha_s)]ds \right].$$

(2.5)

On one hand, for any $\alpha \in \mathcal{A}_0$, by the flow property for the SDE we have

$$X^{0, \xi, \alpha}_s = X^{t, X^{0, \xi, \alpha}_r, \alpha'}_s, \quad s \in [t, T],$$

where $\alpha' := \alpha|_{[t, T]} \in \mathcal{A}_t$. Then,

$$J(0, \xi, \alpha) = \mathbb{E} \left[ g(X^T_T, \alpha_T) + \int_t^T f(s, X^{s, X^{0, \xi, \alpha}_r, \alpha'}_s, \alpha'_s)ds + \int_0^t f(s, X^{0, \xi, \alpha}_s, \alpha_s)ds \right]$$

$$= J(t, X^{0, \xi, \alpha}_r, \alpha') + \int_0^t \mathbb{E}[f(s, X^{0, \xi, \alpha}_s, \alpha_s)]ds$$

(2.6)

$$\leq V(t, \mathcal{L}_{X^{0, \xi, \alpha}_r}) + \int_0^t \mathbb{E}[f(s, X^{0, \xi, \alpha}_s, \alpha_s)]ds \leq \tilde{V}(0, \mu).$$
By the arbitrariness of \( \alpha \), we obtain \( V(0, \mu) \leq \tilde{V}(0, \mu) \).

On the other hand, for any \( \varepsilon > 0 \), by the definition of \( \tilde{V}(0, \mu) \), there exists \( \alpha^\varepsilon \in \mathcal{A}_0 \) such that

\[
V(t, \mathcal{L}_{X_t^{0,\xi,\alpha^\varepsilon}}) + \int_0^t \mathbb{E}[f(s, X_s^{0,\xi,\alpha^\varepsilon}, \alpha_s^\varepsilon)]ds \geq \tilde{V}(0, \mu) - \frac{\varepsilon}{2}.
\]

Moreover, by the definition of \( V(t, \mathcal{L}_{X_t^{0,\xi,\alpha^\varepsilon}}) \) there exists \( \tilde{\alpha}^\varepsilon \in \mathcal{A}_t \) such that

\[
J(t, X_t^{0,\xi,\tilde{\alpha}^\varepsilon}, \tilde{\alpha}^\varepsilon) \geq V(t, \mathcal{L}_{X_t^{0,\xi,\tilde{\alpha}^\varepsilon}}) - \frac{\varepsilon}{2}.
\]

Note that \( \tilde{\alpha}^\varepsilon := \alpha 1_{[0,t]} + \alpha^\varepsilon 1_{[t,T]} \in \mathcal{A}_0 \). Then, by the middle line of (2.6),

\[
V(0, \mu) \geq J(0, \xi, \tilde{\alpha}) = J(t, X_t^{0,\xi,\tilde{\alpha}^\varepsilon}, \tilde{\alpha}^\varepsilon) + \int_0^t \mathbb{E}[f(s, X_s^{0,\xi,\alpha^\varepsilon}, \alpha_s^\varepsilon)]ds \\
\geq V(t, \mathcal{L}_{X_t^{0,\xi,\alpha^\varepsilon}}) + \int_0^t \mathbb{E}[f(s, X_s^{0,\xi,\alpha^\varepsilon}, \alpha_s^\varepsilon)]ds - \frac{\varepsilon}{2} \geq \tilde{V}(0, \mu) - \varepsilon.
\]

Because \( \varepsilon > 0 \) is arbitrary, we obtain \( V(0, \mu) \geq \tilde{V}(0, \mu) \).

\[\square\]

**Remark 2.4** Since we are in the simple setting of deterministic control, no regularity or even measurability of \( V \) in terms of \((t, \mu)\) is needed in the above result.

### 2.2 The master equation

In this subsection we derive the master equation associated with the value function \( V \). For this purpose, we first introduce the 2-Wasserstein distance on \( \mathcal{P}_2(\mathbb{R}^d) \): for \( \mu, \mu' \in \mathcal{P}_2(\mathbb{R}^d) \),

\[
\mathcal{W}_2(\mu, \mu') := \inf \left\{ \| \xi - \xi' \|_{L^2} : \xi \in L^2_0(F_T), \xi' \in L^2_0(F_T) \right\}.
\]

Let \( V : \Theta \rightarrow \mathbb{R} \). The time derivative of \( V \) is defined in the standard way:

\[
\partial_t V(t, \mu) := \lim_{\delta \downarrow 0} \frac{V(t + \delta, \mu) - V(t, \mu)}{\delta},
\]

provided the limit exists. Notice that the above is actually the right time derivative. The derivative in terms of \( \mu \) is much more involved. We first lift the function \( V \):

\[
U(t, \xi) := V(t, \mathcal{L}_\xi), \quad \xi \in L^2(F_T).
\]

Assume \( U \) is continuously Fréchet differentiable in \( \xi \), then the Fréchet derivative \( DU(t, \xi) \) can be identified as an element in \( L^2(F_T) \). By Cardaliaguet [2013] (based on Lions’ lecture), there exists a deterministic function \( \partial_\mu V : \Theta \times \mathbb{R}^d \rightarrow \mathbb{R}^d \) such that \( DU(t, \xi) = \partial_\mu V(t, \mu, \xi) \). See also Wu and Zhang [2017] for an elementary proof. This function \( \partial_\mu V \) is our spatial derivative, which is called \( L \)-derivative or Wasserstein gradient. In particular, the \( L \)-derivative is also a Gâteaux derivative:

\[
\mathbb{E} \left[ \partial_\mu V(t, \mu, \xi) \cdot \xi' \right] = \lim_{\varepsilon \downarrow 0} \frac{V(t, \mathcal{L}_\xi + \varepsilon \xi') - V(t, \mu)}{\varepsilon},
\]

for all \( \xi \in L^2_0(F_T) \) and \( \xi' \in L^2(F_T) \).

**Remark 2.5** We shall remark that \( \partial_\mu V(t, \mu, \cdot) : \mathbb{R}^d \rightarrow \mathbb{R} \) is unique only in the support of \( \mu \). Assume \( \partial_\mu V \) exists and can be extended to \( \mathbb{R}^d \) continuously, then we may define \( \partial_\xi \partial_\mu V \) as the standard derivative of \( \partial_\mu V \) in terms of the third variable. Obviously, \( \partial_\xi \partial_\mu V(t, \mu, \cdot) \) is also well defined only in the support of \( \mu \). In this paper we shall always understand \( \partial_\mu V \) in this way. In particular, we emphasize that the possible non-uniqueness of \( \partial_\mu V(t, \mu, \cdot) \) outside of the support of \( \mu \) does not affect the Itô formula (2.11) below, which is what we will actually need in the paper.
Definition 2.6 (i) Let $C^1_{Lip,b}(P_2(\mathbb{R}^d))$ denote the space of functions $f : P_2(\mathbb{R}^d) \rightarrow \mathbb{R}$ such that $\partial_\mu f$ exists everywhere and $\partial_f : P_2(\mathbb{R}^d) \times \mathbb{R}^d \rightarrow \mathbb{R}^d$ is bounded and Lipschitz continuous.

(ii) Let $C^2_{Lip,b}(P_2(\mathbb{R}^d))$ denote the subset of $C^1_{Lip,b}(P_2(\mathbb{R}^d))$ such that

- For each $x \in \mathbb{R}$, all components of $\partial_\mu f(\cdot, x)$ belongs to $C^1_{Lip,b}(P_2(\mathbb{R}^d))$;
- $\partial^2 f : P_2(\mathbb{R}^d) \times \mathbb{R}^d \rightarrow \mathbb{R}^{d \times d}$ is bounded and Lipschitz continuous;
- $\partial_x \partial_\mu f : P_2(\mathbb{R}^d) \times \mathbb{R}^d \rightarrow \mathbb{R}^{d \times d}$ exists and it is bounded and Lipschitz continuous.

(iii) Let $C^{1,2}(\Theta) := C^1_{Lip,b}(\Theta)$ denote the space of $V : \Theta \rightarrow \mathbb{R}$ such that

- $V(\cdot, \mu) \in C^1([0,T])$, for any $\mu \in P_2(\mathbb{R}^d)$;
- $V(t, \cdot) \in C^2_{Lip,b}(P_2(\mathbb{R}^d))$, for any $t \in [0,T]$.

The following Itô formula is crucial for the results developed here, see e.g. Buckdahn et al. [2017] and Chassagneux et al. [2015].

Lemma 2.7 Let $V \in C^{1,2}(\Theta)$ and $dX_t = bdt + \sigma dW_t$, for some $\mathbb{F}$-progressively measurable processes $b$ and $\sigma$ such that $\mathbb{E}[^T_0 |b|^2 + |\sigma|^4] < \infty$. Then

$$\frac{d}{dt} V(t, \mathcal{L}_{X_t}) = \partial_t V(t, \mathcal{L}_{X_t}) + \mathbb{E} \left[ b \cdot \partial_\mu V + \frac{1}{2} \sigma \sigma^\top : \partial_x \partial_\mu V \right] (t, \mathcal{L}_{X_t}, X_t).$$

(2.11)

The main result of this section is the following verification theorem.

Theorem 2.8 Let Assumption 2.1 hold and $V \in C^{1,2}(\Theta)$. Then $V$ is the value function defined by (2.3) if and only if $V$ is a classical solution to the master equation:

$$\partial_t V(t, \mu) + H(t, \mu, \partial_\mu V, \partial_x \partial_\mu V) = 0, \quad V(T, \mu) = \mathbb{E}[g(\xi)],$$

(2.12)

where, for $p : \Theta \times \mathbb{R}^d \rightarrow \mathbb{R}^d$ and $q : \Theta \times \mathbb{R}^d \rightarrow \mathbb{R}^{d \times d}$,

$$H(t, \mu, p, q) := \sup_{a \in A} h(t, \mu, p, q, a),$$

(2.13)

$$h(t, \mu, p, q, a) := \mathbb{E} \left[ b(t, \xi, a) \cdot p(t, \mu, \xi) + \frac{1}{2} \sigma \sigma^\top (t, \xi, a) \cdot q(t, \mu, \xi) + f(t, \xi, a) \right].$$

Consequently, the above master equation has at most one classical solution in $C^{1,2}(\Theta)$.

Proof. We first assume $V \in C^{1,2}(\Theta)$ is defined by (2.3). Then clearly $V$ satisfies the terminal condition in (2.12). Now fix $(t, \mu) \in \Theta$ and $\xi \in L^2_{\mathbb{P}}(\mathcal{F}_t)$. Recall (2.13) and apply Itô formula (2.11) on (2.4) with $t_1 = t$, $t_2 = t + \delta$, we have

$$\sup_{a \in A} \int_{t}^{t+\delta} \left[ \partial_t V(s, \mathcal{L}_{X^t_{s+t}, \xi}) + h(s, \mathcal{L}_{X^t_{s+t}, \xi}, \partial_\mu V, \partial_x \partial_\mu V, \alpha_s) \right] ds = 0.$$ 

(2.14)

Under Assumption 2.1, $W_2(\mathcal{L}_{X^t_{s+t}, \xi}, \mu) \leq \|X^t_{s+t, \xi} - \xi\|_{L^2} \leq C \sqrt{\delta}$, for $s \in [t, t + \delta]$, where $C$ may depend on $\|\xi\|_{L^2}$. By the required regularity on $V$, there exists a modulus of continuity function $\rho$ such that, again for $a \in A_t$ and $s \in [t, t + \delta]$,

$$|\partial_t V(s, \mathcal{L}_{X^t_{s+t}, \xi}) - \partial_t V(t, \mu)| + |\partial_\mu V(s, \mathcal{L}_{X^t_{s+t}, \xi}, X^t_{s+t, \xi}) - \partial_\mu V(t, \mu, \xi)| + |\partial_\mu \partial_\mu V(s, \mathcal{L}_{X^t_{s+t}, \xi}, X^t_{s+t, \xi}) - \partial_\mu \partial_\mu V(t, \mu, \xi)| \leq \rho(C \sqrt{\delta} + |X^t_{s+t, \xi} - \xi|),$$

(2.15)

$$|b(s, X^t_{s+t, \xi}, \alpha_s) - b(t, \xi, \alpha_s)| + |\sigma(s, X^t_{s+t, \xi}, \alpha_s) - \sigma(t, \xi, \alpha_s)| + |f(s, X^t_{s+t, \xi}, \alpha_s) - f(t, \xi, \alpha_s)| \leq \rho(\delta + |X^t_{s+t, \xi} - \xi|).$$

These lead to, for a possibly different modulus of continuity function $\rho'$,

$$|h(s, \mathcal{L}_{X^t_{s+t, \xi}}, \partial_\mu V, \partial_x \partial_\mu V, \alpha_s) - h(t, \mu, \partial_\mu V, \partial_x \partial_\mu V, \alpha_s)| \leq \rho'(\delta).$$

(2.16)
Then, by (2.14) we have, when $\delta \to 0$,
\[
\partial_t V(t, \mu) + \sup_{\alpha \in A_t} \frac{1}{\delta} \int_t^{t+\delta} h(t, \mu, \partial_\mu V, \partial_s \partial_\mu V, \alpha_s) ds = o(1).
\]

On one hand, this clearly implies $\partial_t V(t, \mu) + H(t, \mu, \partial_\mu V, \partial_s \partial_\mu V) \geq 0$. On the other hand, by restricting the above $\alpha$ to constant functions we obtain $\partial_t V(t, \mu) + H(t, \mu, \partial_\mu V, \partial_s \partial_\mu V) \leq 0$. That is, $V$ satisfies (2.12).

We now assume $V \in C^{1,2}(\Theta)$ is a classical solution of (2.12), and want to verify (2.3). Fix $(t, \mu) \in \Theta$ and $\xi \in B_{2C}(F_t)$. For any $\alpha \in A_t$, by Itô formula (2.11) we have
\[
J(t, \xi, \alpha) = \mathbb{E}[g(X^{t, \xi, \alpha}_T)] + \int_t^T \mathbb{E}[f(s, X^{t, \xi, \alpha}_s, \alpha_s)] ds
\]
\[
= V(T, \mathcal{L}_{X^{t, \xi, \alpha}_T}) + \int_t^T \mathbb{E}[f(s, X^{t, \xi, \alpha}_s, \alpha_s)] ds
\]
\[
= V(t, \mu) + \int_t^T \left[ \partial_t V(s, \mathcal{L}_{X^{t, \xi, \alpha}_s}) + h(s, \mathcal{L}_{X^{t, \xi, \alpha}_s}, \partial_\mu V, \partial_s \partial_\mu V, \alpha_s) \right] ds
\]
\[
\leq V(t, \mu) + \int_t^T \left[ \partial_h V(s, \mathcal{L}_{X^{t, \xi, \alpha}_s}) + H(s, \mathcal{L}_{X^{t, \xi, \alpha}_s}, \partial_\mu V, \partial_s \partial_\mu V) \right] ds
\]
\[
= V(t, \mu).
\]
(2.17)

On the other hand, fix $\varepsilon > 0$ and $n \geq 1$, and denote $t_i := t + \frac{i}{n}[T - t]$, $i = 0, \ldots, n$. We construct an $\alpha^{n, \varepsilon} : A_t$ as follows. First, there exists $a_0^* \in A$ such that
\[
h(t, \mu, \partial_\mu V, \partial_s \partial_\mu V, a_0^*) \geq H(t, \mu, \partial_\mu V, \partial_s \partial_\mu V) - \frac{\varepsilon}{T - t},
\]
Define $\alpha^{n, \varepsilon}_0 := a_0^*$ for $s \in [t_0, t_1)$. Next, there exists $a_1^* \in A$ such that
\[
h(t_1, \mathcal{L}_{X^{t_1, \xi, \alpha^{n, \varepsilon}_0}_s}, \partial_\mu V, \partial_s \partial_\mu V, a_1^*) \geq H(t_1, \mathcal{L}_{X^{t_1, \xi, \alpha^{n, \varepsilon}_0}_s}, \partial_\mu V, \partial_s \partial_\mu V) - \frac{\varepsilon}{T - t},
\]
Define $\alpha^{n, \varepsilon}_1 := a_1^*$ for $s \in [t_1, t_2)$. Repeat the procedure and define $\alpha^{n, \varepsilon}_i$ for $s \in [t_i, t_{i+1})$ for $i = 1, \ldots, n - 1$. Clearly $\alpha^{n, \varepsilon} \in A_t$. Now, by the second equality of (2.17) and then by (2.15) and (2.16), as $n \to \infty$, we have
\[
J(t, \xi, \alpha^{n, \varepsilon}) - V(t, \mu)
\]
\[
= \sum_{i=0}^{n-1} \int_{t_i}^{t_{i+1}} \left[ \partial_t V(s, \mathcal{L}_{X^{t, \xi, \alpha^{n, \varepsilon}}_s}) + h(s, \mathcal{L}_{X^{t, \xi, \alpha^{n, \varepsilon}}_s}, \partial_\mu V, \partial_s \partial_\mu V, \alpha^{n, \varepsilon}_s) \right] ds
\]
\[
= \sum_{i=0}^{n-1} \int_{t_i}^{t_{i+1}} \left[ \partial_t V(s, \mathcal{L}_{X^{t, \xi, \alpha^{n, \varepsilon}}_s}) + h(s, \mathcal{L}_{X^{t, \xi, \alpha^{n, \varepsilon}}_s}, \partial_\mu V, \partial_s \partial_\mu V, \alpha^{n, \varepsilon}_s) \right] ds + o(1)
\]
\[
\geq \sum_{i=0}^{n-1} \int_{t_i}^{t_{i+1}} \left[ \partial_t V(s, \mathcal{L}_{X^{t, \xi, \alpha^{n, \varepsilon}}_s}) + H(s, \mathcal{L}_{X^{t, \xi, \alpha^{n, \varepsilon}}_s}, \partial_\mu V, \partial_s \partial_\mu V) - \varepsilon \right] ds + o(1)
\]
\[
= o(1) - \varepsilon.
\]
Here the $o(1)$ may depend on $\|\xi\|_{L^2}$ and we have used the fact that
\[
\sup_{t \leq s \leq T} \|X^{t, \xi, \alpha^{n, \varepsilon}}_s\|_{L^2} \leq C[1 + \|\xi\|_{L^2}].
\]
Sending $n \to \infty$, we see that
\[
\sup_{\alpha \in A_t} J(t, \xi, \alpha) \geq V(t, \mu) - \varepsilon.
\]
By the arbitrariness of $\varepsilon$, we obtain the desired inequality, and hence $V$ is indeed the value function defined by (2.3).

\[ \text{Remark 2.9} \] While we shall provide some positive results in the next section, in general it is difficult to expect classical solutions for nonlinear master equations. There have been some studies on viscosity solutions to such master equations. For example, Pham and Wei [2015] proposed a notion of viscosity solution by first lifting the function $V$ to $U$ in the sense of (2.9) and then studying the viscosity property of $U$ in the Hilbert space $L_2^2(\mathcal{F}_T)$. More recently, Wu and Zhang [2018] proposed an intrinsic notion of viscosity solutions in the Wasserstein space directly, which, in particular, is consistent with the classical solution in Theorem 2.8 when $V$ is smooth.

### 2.3 The optimal control

We now turn to the optimal control.

**Theorem 2.10** Let Assumption 2.1 hold and $V \in C^{1,2}(\Theta)$ be the classical solution to the master equation (2.12)-(2.13). Assume further that

(i) the Hamiltonian $H(t, \mu, \partial_\nu V, \partial_\mu V)$ defined by (2.13) has an optimal control $a^* = I(t, \mu) \in A$, for any $(t, \mu) \in \Theta$, where $I : [0, T] \times \mathcal{P}_2(\mathbb{R}^d) \rightarrow A$ is measurable;

(ii) for a fixed $(t, \mu) \in \Theta$ and $\xi \in L_2^2(\mathcal{F}_t)$, the McKean-Vlasov SDE,

\[
X^*_t = \xi + \int_t^s b(r, X^*_r, I(r, \mathcal{L}X^*_r))dr + \int_t^s \sigma(r, X^*_r, I(r, \mathcal{L}X^*_r))dW_r.
\]

has a (strong) solution $X^*$;

Then $\alpha^*_s := I(s, \mathcal{L}X^*_s), s \in [t, T]$, is an optimal control for the optimization problem (2.3) with this fixed $(t, \mu)$.

**Proof.** Note that $X^* = X^t, \xi, \alpha^*$. Set $\alpha = \alpha^*$ in (2.17). By optimality condition (i) we see that equality holds for (2.17), namely $J(t, \xi, \alpha^*) = V(t, \mu)$, implying that $\alpha^*$ is optimal.

As in standard control theory, in general, the existence of the classical solution $V$ is not sufficient for the existence of the optimal control. In particular, the McKean-Vlasov SDE (2.18) may not have a solution, even if $I$ exists. At below we provide a sufficient condition.

**Theorem 2.11** Let all the conditions in Theorem 2.10 hold true, except possibly the (ii) there. Assume further $b, \sigma$ are bounded and continuous in $a$, and $I : \Theta \rightarrow A$ is continuous. Then the McKean-Vlasov SDE (2.18) has a strong solution for any $(t, \mu)$, and hence the optimization problem (2.3) has an optimal control.

**Proof.** Without loss of generality, we prove the result only at $(0, \mu)$. Fix $\xi \in L_2^2(\mu)$. For any $\alpha \in \mathcal{A}_0$, denote

\[
X^\alpha_t = \xi + \int_0^t b(s, X^\alpha_s, \alpha_s)ds + \int_0^t \sigma(s, X^\alpha_s, \alpha_s)dW_s.
\]

Under Assumption 2.1, it is clear that

\[
\mathbb{E}[|X^\alpha_t - X^\beta_t|^2] \leq C_\alpha|t - s|, \quad \text{and thus} \quad \mathcal{W}_2(\mathcal{L}X^\alpha_t, \mathcal{L}X^\beta_t) \leq C_\alpha \sqrt{|t - s|},
\]

where the constant $C_\alpha$ may depend on $\mu$, but does not depend on $\alpha$. Moreover, assume $|b|, |\sigma| \leq L$. Let $\mathcal{D}_\alpha(\mu)$ denote the set of $\mathcal{L}X_t$, where $t \in [0, T], X_t = X^\alpha_0 + \int_0^t b ds + \int_0^t \sigma dW_s$ in some arbitrary probability
space with $L_{X_t} = \mu$ and $|\hat{b}|, |\hat{\sigma}| \leq L$. As in Wu and Zhang [2018] Lemma 3.1, one can easily show that $\mathcal{D}_L(\mu)$ is compact under $\mathcal{W}_2$. Since $I$ is continuous in $\Theta$, then it is uniformly continuous on $[0, T] \times \mathcal{D}_L(\mu)$ with certain modulus of continuity function $\rho_\mu$, which may depend on $\mu$. Clearly $L_{X_t^0} \in \mathcal{D}_L(\mu)$ for all $\alpha \in \mathcal{A}_0$ and $t \in [0, T]$. Then we have

$$\left| I(t, L_{X_t^0}) - I(s, L_{X_s^0}) \right| \leq \rho_\mu(|t - s|), \quad \text{for all } \alpha \in \mathcal{A}_0. \quad (2.20)$$

Denote

$$\mathcal{A}_0(\rho_\mu) := \left\{ \alpha \in \mathcal{A}_0 : |\alpha_t - \alpha_s| \leq \rho_\mu(t - s), \quad 0 \leq s < t \leq T \right\}. \quad (2.21)$$

We now define a mapping $\Phi : \mathcal{A}_0(\rho_\mu) \to \mathcal{A}_0(\rho_\mu)$ by $\Phi_t(\alpha) := I(t, L_{X_t^\alpha})$, where (2.20) ensures that $\Phi(\alpha) \in \mathcal{A}_0(\rho_\mu)$ for all $\alpha \in \mathcal{A}_0(\rho_\mu)$. One can easily show that $\mathcal{A}_0(\rho_\mu)$ is convex and compact under the uniform norm, and $\Phi$ is continuous. Then, applying the Schauder’s fixed point theorem, $\Phi$ has a fixed point $\alpha^* \in \mathcal{A}_0(\rho_\mu)$: $\Phi(\alpha^*) = \alpha^*$. Now it is clear that $X^* := X^{\alpha^*}$ satisfies (2.18), and hence $\alpha^*$ is an optimal control. 

**Remark 2.12** In this section, we used the dynamic programming principle. Since the control here is deterministic and thus falls in strong formulation, one may also use the stochastic maximum principle, provided the optimal control exists. We will present heuristic arguments in Appendix A to show how the McKean-Vlasov SDEs come to play naturally.

### 3 Classical solution of a nonlinear master equation

The existence of classical solutions for nonlinear master equations is a very challenging problem. We shall leave the general case to future research. In this section we study a special type of master equations. Consider the equation (2.12)-(2.13) with

$$\sigma = I_d, \quad b = b(t, a), \quad f = f(t, a).$$

Then (2.12) becomes:

$$\partial_t V(t, \mu) + \frac{1}{2} \mathbb{E} \left[ \text{tr} (\partial_x \partial_\mu V(t, \mu, \xi)) \right] + \sup_a \left[ b(t, a) \cdot \mathbb{E} [\partial_\mu V(t, \mu, \xi)] + f(t, a) \right] = 0. \quad (3.1)$$

This is a special case of the following nonlinear master equation:

$$\partial_t V(t, \mu) + \frac{1}{2} \mathbb{E} \left[ \text{tr} (\partial_x \partial_\mu V(t, \mu, \xi)) \right] + F(t, \mathbb{E} [\partial_\mu V(t, \mu, \xi)]) = 0, \quad V(T, \mu) = \mathbb{E} [g(\xi)]. \quad (3.1)$$

**Theorem 3.1** Let $F$ and $g$ be smooth enough with bounded derivatives. Assume one of the following two conditions hold true:

(i) $T$ is sufficiently small;

(ii) $d = 1$; and either $\partial_{xx} g > 0 > \partial_{xx} F$, or $\partial_{xx} g < 0 < \partial_{xx} F$.

Then the master equation (3.1) has a classical solution $V \in C^{1,2}(\Theta)$.

**Proof.** We shall proceed in two steps.

**Step 1.** Consider the following master equation which is linear in $\partial_\mu \tilde{V}$:

$$\partial_t \tilde{V}(t, \mu) + \frac{1}{2} \mathbb{E} \left[ \text{tr} (\partial_x \partial_\mu \tilde{V}(t, \mu, \xi)) \right] + \partial_\mu F(t, \tilde{V}(t, \mu)) \mathbb{E} [\partial_\mu \tilde{V}(t, \mu, \xi)] = 0, \quad \tilde{V}(T, \mu) = \mathbb{E} [\partial_\mu g(\xi)].$$

**Step 2.**
We shall prove in Step 2 below that, under (i) or (ii) the above master equation has a unique classical solution $\tilde{V}$. We next consider the linear master equation:

$$\partial_t V(t, \mu) + \frac{1}{2} \mathbb{E} \left[ \text{tr} \left( \partial_\mu \partial_\mu V(t, \mu, \xi) \right) \right] + F(t, \tilde{V}(t, \mu)) = 0,$$

(3.3)

Then clearly $V$ is also smooth. It remains to verify that the above $V$ satisfies (3.1). Indeed, by (3.3) we see that,

$$V(t, \mu) = \mathbb{E}[g(X_t^\xi)] + \int_t^T F(s, \tilde{V}(s, \mathcal{L}_{X_s^\xi}))ds,$$

(3.4)

where $X_t^\xi := \xi + W_s - W_t$. Differentiating with respect to $\mu$, we obtain

$$\mathbb{E}[\partial_\mu V(t, \mu, \xi)] = \mathbb{E} \left[ \partial_x g(X_t^\xi) \right] + \left[ \int_t^T \partial_x F(s, \tilde{V}(s, \mathcal{L}_{X_s^\xi})) \cdot \partial_\mu \tilde{V}(s, \mathcal{L}_{X_s^\xi}, X_s^\xi) ds \right].$$

(3.5)

That is, $\nabla(t, \mu) := \mathbb{E}[\partial_\mu V(t, \mu, \xi)]$ satisfies the following linear master equation:

$$\partial_t \nabla(t, \mu) + \frac{1}{2} \mathbb{E} \left[ \text{tr} \left( \partial_\mu \partial_\mu \nabla(t, \mu, \xi) \right) \right] + \partial_\mu F(t, \tilde{V}(t, \mu)) \cdot \mathbb{E}[\partial_\mu \tilde{V}(t, \mu, \xi)] = 0,$$

$$\nabla(T, \mu) = \mathbb{E}[\partial_\mu g(\xi)].$$

However, by (3.2), $\tilde{V}$ also satisfies the above master equation. Then by the uniqueness of classical solutions, we have $\tilde{V}(t, \mu) = \nabla(t, \mu) = \mathbb{E}[\partial_\mu V(t, \mu, \xi)]$. Plugging this into (3.3), we see that $V$ satisfies (3.1).

Step 2. We now prove the wellposedness of (3.2) under (i) or (ii). When $T$ is small, the arguments are rather standard, see e.g. Chassagneux et al. [2015]. We now assume (ii) holds true. Without loss of generality, we assume $F$ is convex in $x$ and $g$ is concave. For any $y \in \mathbb{R}$, define

$$\Phi(y; t, \mu) := \mathbb{E} \left[ \partial_x g(x + W_T - W_t + \int_t^T \partial_x F(s, y) ds) \right],$$

(3.6)

$$\Psi(y, t, \mu) := \Phi(y; t, \mu) - y,$$

where $\mathcal{L}_\xi = \mu$ and $W_T - W_t$ is independent of $\xi$. It is straightforward to show that $\Phi$ is smooth in $(y, t, \mu)$ and, for any $y$, $\Phi(y; \cdot)$ solves the following linear master equation:

$$\partial_t \Phi(y; t, \mu) + \frac{1}{2} \mathbb{E} \left[ \text{tr} \left( \partial_x \partial_x \Phi(y; t, \mu, \xi) \right) \right] + \partial_x F(t, y) \mathbb{E}[\partial_\mu \Phi(y; t, \mu, \xi)] = 0.$$

(3.7)

Under our conditions, $\partial_x g$ is decreasing and $\partial_x F$ is increasing in $y$, then by (3.6) $\Phi$ is decreasing in $y$ and thus $\partial_\mu \Psi \leq -1$, so $y \rightarrow \Psi(y, t, \mu)$ has an inverse function $\Psi^{-1}$, which is also smooth. Since $\partial_x g$ is bounded by some constant $C_0$, then $|\Phi(y; t, \mu)| \leq C_0$, and thus $\Psi(0, t, \mu) \leq 0 \leq \Psi^{-1}(0, t, \mu)$ for any fixed $(t, \mu)$. In particular, 0 is in the range of $\Psi(:, t, \mu)$ for any fixed $(t, \mu)$. Define $U(t, \mu) := \Psi^{-1}(0, t, \mu)$, then $U$ is smooth. Note that $U(t, \mu) = \Phi(U(t, \mu); t, \mu)$. Apply the chain rule (which is obvious from the definitions), we have

$$\partial_t U = \partial_t \Phi + \partial_y \Phi \partial_\mu U, \quad \partial_\mu U = \partial_\mu \Phi + \partial_y \Phi \partial_\mu U, \quad \partial_x \partial_\mu U = \partial_x \partial_y \Phi + \partial_y \Phi \partial_\mu U.$$

Namely, denoting $c := 1 - \partial_\mu \Phi(U(t, \mu); t, \mu) \geq 1$,

$$\partial_t U(t, \mu; t, \mu) = c \partial_t U(t, \mu), \quad \partial_\mu U(t, \mu; t, \mu) = c \partial_\mu U(t, \mu, \cdot),$$

$$\partial_x \partial_\mu U(t, \mu; t, \mu) = c \partial_x \partial_\mu U(t, \mu, \cdot).$$

Plug these into (3.7) with $y = U(t, \mu)$, we obtain that $U$ satisfies (3.2).
3.1 An example

We now consider a special case. For some \( R > 0 \), which will be specified later, set
\[
d = 1, \quad A = [-R, R], \quad b(t, x, a) = a, \quad \sigma = 1, \quad f(t, x, a) = -\frac{1}{2}a^2.
\]
(3.8)

Then
\[
h(t, \mu, p, q, a) = \frac{1}{2}E[q(t, \mu, \xi)] + aE[p(t, \mu, \xi)] - \frac{1}{2}a^2,
\]
\[
H(t, \mu, p, q) = \frac{1}{2}E[q(t, \mu, \xi)] + F(E[p(t, \mu, \xi)]),
\]
where \( F(x) = \frac{1}{2}|x|^21_{\{|x| \leq R\}} + |R|x| - \frac{1}{2}R^21_{\{|x| > R\}} \).
\]

and thus (2.12) becomes:
\[
\partial_t V + \frac{1}{2}E[\partial_x \partial_x V(t, \mu, \xi)] + F(E[\partial_x V(t, \mu, \xi)]) = 0, \quad V(T, \mu) = E[g(\xi)].
\]
(3.10)

Notice that \( F \) is convex, however, it is in \( C^1(\mathbb{R}) \) but not in \( C^2(\mathbb{R}) \).

**Theorem 3.2** Assume \( g \) is smooth enough with bounded derivatives, and in particular \( |\partial_x g| \leq C_0 < R \). Then, either for \( T \) small enough, or \( d = 1 \) and \( g \) is concave,

(i) the master equation (3.10) has a unique classical solution \( V \) such that
\[
\left| E[\partial_x V(t, \mu, \xi)] \right| \leq C_0, \quad (t, \mu) \in \Theta, \xi \in \mathbb{L}_2^2(F_t);
\]
(3.11)

(ii) for any \( (t, \mu) \in \Theta \) and \( \xi \in \mathbb{L}_2^2(F_t) \), the McKean-Vlasov SDE (2.18) with \( I(t, \mu) := E[\partial_x V(t, \mu, \xi)] \)
has a solution \( X^* \);

(iii) for any \( (t, \mu) \in \Theta \), the optimization problem (2.3) has an optimal control: \( \alpha^*_s := I(s, \mathcal{L}_X) \).

**Proof.** Let \( \tilde{F} : \mathbb{R} \to \mathbb{R} \) be a smooth function such that
\[\tilde{F} \] is convex and \( \tilde{F}(x) = F(x) \) for \( |x| \leq C_0 \) or \( |x| \geq R \).

Applying Theorem 3.1, the master equation (3.10) corresponding to \( \tilde{F} \) has a classical solution \( V \). Introduce the conjugate of \( \tilde{F} \): \( \tilde{f}(a) := \sup_{x \in \mathbb{R}} |ax - \tilde{F}(x)|, \quad a \in A \). By the convexity of \( \tilde{F} \), we have \( \tilde{F}(x) = \sup_{a \in A} |ax - \tilde{f}(a)| \). Then by Theorem 2.8 we see that
\[
V(t, \mu) = \sup_{a \in A} \tilde{J}(t, \xi, \alpha), \quad \text{where}
\]
(3.12)
\[
\tilde{X}^{t, \xi, \alpha} := \xi + \int_t^T \alpha_s dr + W_s - W_t, \quad \tilde{J}(t, \xi, \alpha) := E[g(\tilde{X}^{t, \xi, \alpha})] - \int_t^T \tilde{f}(\alpha_s)ds.
\]

For any \( t \in [0, T], \xi, \xi' \in \mathbb{L}^2(F_t) \), and \( \alpha \in A \), under our conditions it is clear that
\[
|\tilde{J}(t, \xi, \alpha) - \tilde{J}(t, \xi', \alpha)| \leq C_0 E[|\xi - \xi'|].
\]

Since \( \xi, \xi' \) are arbitrary, then it follows from (3.12) that
\[
|V(t, \mu) - V(t, \mu')| \leq C_0 W_2(\mu, \mu'),
\]
which implies (3.11) immediately. Since \( \tilde{F}(x) = F(x) = \frac{1}{2}x^2 \) for \( |x| \leq C_0 \), then (3.11) implies further that \( V \) is a classical solution to master equation (3.10) corresponding to \( F \).

(ii) Clearly in this case the optimal argument of the Hamiltonian \( F \) leads to \( I(t, \mu) = E[\partial_x V(t, \mu, \xi)] \), which is continuous. Then (ii) follows from Theorem 2.11.

Finally, (iii) follows directly from Theorem 2.10.

We remark that in this example it is more natural to set \( A = \mathbb{R} \) and all the results still hold true. The constraint \( A = [-R, R] \) is to ensure the uniform requirement in Assumption 2.1 (i), which is more convenient for establishing the general theory, but can be relaxed.

12
4 The General Case

In this section we investigate the general case \( T > \mu \).

4.1 Strong formulation with closed loop controls

In this subsection we illustrate how the information delay naturally lead to the path dependence of the value function, even if the coefficients \( b, \sigma, f, g \) in (2.1) depend only on the current state of \( X \). It is easier to show the idea in strong formulation, namely we fix a probability space and the state process \( X^\alpha \) is controlled, but we emphasize that we shall use closed loop controls, both for practical and for theoretical reasons.

As in Section 2, let \((\Omega, \mathcal{F}, \mathbb{P})\) be a filtered probability space on \([0, T]\), and \(W\) an \(\mathbb{F}\)-Brownian motion under \(\mathbb{P}\). For simplicity, in this subsection we assume \( T \leq 2\mu \), which will not be required in later subsections. Let \( t \in (\mu, T]\), and \( \xi \) be an \(\mathbb{F}\)-progressively measurable process on \([0, t]\). Consider the following counterpart of (2.1):

\[
X_s^{t,\xi,\alpha} = \xi_t + \int_t^s b(r, X_r^{t,\xi,\alpha}, \alpha_r(\xi_{[r,r-\mu]}))dr + \int_t^s \sigma(r, X_r^{t,\xi,\alpha}, \alpha_r(\xi_{[r,r-\mu]}))dW_r;
\]

\[
J(t, \xi, \alpha) := \mathbb{E} \left[ g(X_T^{t,\xi,\alpha}) + \int_t^T f(s, X_s^{t,\xi,\alpha}, \alpha_s(\xi_{[s,s-\mu]}))ds \right].
\]

(4.1)

Similar to Lemma 2.2, \( J(t, \xi, \alpha) \) depends on \( \xi \) only through the law of the stopped process \( \xi_{[0,t]} \). That is, if \( \xi' \) is another process such that \( \mathcal{L}_{\xi_{[0,t]}} = \mathcal{L}_{\xi'_{[0,t]}} \), then \( J(t, \xi, \alpha) = J(t, \xi', \alpha) \). Consequently, the following value function is also law invariant:

\[
\tilde{V}(t, \xi) := \sup_{\alpha \in \mathcal{A}_t} J(t, \xi, \alpha).
\]

(4.2)

We emphasize that the above law invariant property relies on the law of the stopped process \( \xi_{[0,t]} \), rather than the law of the current state \( \xi_t \).

Example 4.1 Let \( d = 1 \), \( A = [-1, 1] \), \( b(t, x, a) = a \), \( \sigma(t, x, a) = 1 \), \( f(t, x, a) = 0 \), \( g(x) = x^2 \), \( T = 2\mu \), \( t = \frac{T}{2} \). Set

\[
\xi_s = W_s, 0 \leq s \leq t, \quad \xi'_s := W_{3(s-t)}1_{[s,t]}(s).
\]

(4.3)

Then \( \xi_t = \xi'_t = W_t \) but in general \( \tilde{V}(t, \xi) \neq \tilde{V}(t, \xi') \).

Proof. First, since \( \xi'_t = 0 \), \( s \leq \mu \), then \( \alpha_r(\xi'_{[0,r-\mu]}) = \alpha_r(0) \) is deterministic. Thus

\[
J(t, \xi', \alpha) = \mathbb{E} \left[ |W_t + \int_t^T \alpha_r(0)dr + W_T - W_t|^2 \right] = \int_t^T \alpha_r(0)dr^2 + T.
\]

This implies

\[
\tilde{V}(t, \xi') = T + (T - t)^2 = 2\mu + \frac{1}{4}t^2.
\]

On the other hand, denote \( \beta_r := \alpha_{r+\mu}(W_{[0,r]}) \) which is \( \mathcal{F}_r \)-measurable, then

\[
J(t, \xi, \alpha) = \mathbb{E} \left[ |W_t + \int_{t-\mu}^{T-\mu} \beta_r dr + W_T - W_t|^2 \right]
\]

\[
= \mathbb{E} \left[ |\int_{t-\mu}^{T-\mu} \beta_r dr|^2 + 2 \int_{t-\mu}^{T-\mu} W_r \beta_r dr \right] + T \geq 2\mathbb{E} \left[ \int_{t-\mu}^{T-\mu} W_r \beta_r dr \right] + 2\mu.
\]

13
By choosing $\beta_r = \text{sign}(W_r)$, we have

$$\tilde{V}(t, \xi) \geq 2\mathbb{E}\left[\int_{\frac{h}{2}}^{h} |W_r| dr\right] + 2h = 2h + ch^2,$$

where $c > 0$ is a generic constant independent of $h$. Then clearly $\tilde{V}(t, \xi) > \tilde{V}(t, \xi')$, when $h$ is small enough. 

We also remark that it is crucial to use closed loop controls. If we use open loop controls with delay, namely $\alpha_s = \alpha_s(W_{[0,s-n]})$, then for each $\alpha$, obviously $J(t, \xi, \alpha)$ would depend on the joint law of $(\xi, W)$ on $[0, t]$. The following example shows that the corresponding value function $\tilde{V}(t, \xi)$ may also violate the law invariant property.

**Example 4.2** Consider the same setting in Example 4.1, but replace (4.3) with

$$\tilde{\xi}_s = [W_s - W_n]1_{[n,t]}(s), \quad \tilde{\xi}'_s = W_{s-n}1_{[n,t]}(s), \quad 0 \leq s \leq t.$$

Then $L_{\tilde{\xi}_{[0,t]}} = L_{\tilde{\xi}'_{[0,t]}}$. However, if we use open loop controls but still denote the value function as $\tilde{V}$, then $\tilde{V}(t, \xi) \neq \tilde{V}(t, \xi')$.

**Proof.** First, note that $\alpha_s = \alpha_s(W_{[0,s-n]})$ is $\mathcal{F}_n$-measurable. Then

$$J(t, \xi, \alpha) = \mathbb{E}\left[|W_t - W_n + \int_t^T \alpha_s ds + W_T - W_t|^2\right] = \mathbb{E}\left[\int_t^T \alpha_s ds^2\right] + T - h.$$

This implies

$$\tilde{V}(t, \xi) = T - h + (T - t)^2 = h + \frac{1}{4}h^2.$$ 

On the other hand, denote $\beta_r := \alpha_{r+h}(W_{[0,r]})$ which is $\mathcal{F}_r$-measurable, then

$$J(t, \xi', \alpha) = \mathbb{E}\left[|W_{\bar{t}} + \int_{t-h}^{T-h} \beta_r dr + W_T - W_{\bar{t}}|^2\right] = \mathbb{E}\left[|W_{\bar{t}} + \int_{t-h}^{T-h} \beta_r dr|^2\right] + \frac{h}{2}.$$ 

By choosing $\beta_r = \text{sign}(W_{\bar{t}})$, we have

$$\tilde{V}(t, \xi) \geq \mathbb{E}\left[|W_{\bar{t}} + \frac{h}{2}|^2\right] + \frac{h}{2} = h + \frac{1}{4}h^2 + h\mathbb{E}[|W_{\bar{t}}|] > \tilde{V}(t, \xi).$$

This completes the proof. 

### 4.2 Weak formulation in path-dependent setting

Both for closed loop controls and for path-dependent problems, it is a lot more convenient to use the weak formulation on canonical space. We shall follow the setting of Wu and Zhang [2018].

Let $\Omega := C([0, T]; \mathbb{R}^d)$ be the canonical space equipped with the metric $\|\omega\|_T := \sup_{0 \leq t \leq T} |\omega_t|$, $X$ the canonical process, and $\mathbb{F} = \mathbb{F}^X = \{\mathcal{F}_t\}_{t \in [0, T]}$ the natural filtration generated by $X$. Denote by $\mathcal{P}_2(\mathcal{F}_T)$ the set of probability measures $\mathbb{P}$ on $\mathcal{F}_T$ such that $\mathbb{E}^\mathbb{P}[\|X\|_T^2] < \infty$ and $\Theta_T := [0, T] \times \mathcal{P}_2(\mathcal{F}_T)$. Quite often we will also use $\mu$ to denote elements of $\mathcal{P}_2(\mathcal{F}_T)$. We equip $\mathcal{P}_2(\mathcal{F}_T)$ with the 2-Wasserstein distance $W_2$ which extends (2.7):

$$W_2(\mu, \mu') := \inf \left\{ \left( \mathbb{E} \sup_{0 \leq t \leq T} |\eta_t - \eta'_t|^2 \right)^{\frac{1}{2}} : \mathcal{L}_\eta = \mu, \mathcal{L}_{\eta'} = \mu' \right\},$$

(4.4)
for $\mu, \mu' \in \mathcal{P}_2(\mathcal{F}_T)$, where $\mathcal{L}_n$ is the law of the process $\eta$.

Given $\mu \in \mathcal{P}_2(\mathcal{F}_T)$, let $\mu_{[0,t]}$ denote the $\mu$-distribution of the stopped process $X_{[0,t]}$. For a function $V : \Theta_T \to \mathbb{R}$, we say $V$ is $\mathbb{F}$-adapted if $V(t, \mu) = V(t, \mu_{[0,t]})$ for any $(t, \mu) \in \Theta_T$. For such $V$, we define its time derivative as:

$$
\partial_t V(t, \mu) := \lim_{\delta \to 0} \frac{V(t + \delta, \mu_{[0,t]}) - V(t, \mu_{[0,t]})}{\delta},
$$

where we are freezing the law of $X$ from $t$ to $t+\delta$. The spacial derivative takes the form $\partial_\mu V : \Theta_T \times \Omega \to \mathbb{R}^d$ and is $\mathbb{F}$-progressively measurable, namely measurable in all variables and $\mathbb{F}$-adapted. We emphasize that, as in Dupire [2009], $\partial_\mu V$ is not a Fréchet derivative with respect to the law of the whole stopped process $X_{[0,t]}$, but a derivative with respect to $\mathcal{L}_X$, only. Roughly speaking, by extending the whole setting to the space of càdlàg paths, let $\xi$ be a process on $[0, t]$ such that $\mathcal{L}_\xi = \mu_{[0,t]}$, and $\xi' \in \mathcal{F}_T$-measurable random variable. Then

$$
\mathbb{E}^\mu \left[ \partial_\mu V(t, \mu, \xi) \cdot \xi' \right] := \lim_{\varepsilon \to 0} \frac{V(t, \mathcal{L}_{\xi+\varepsilon[1]}(\xi)) - V(t, \mathcal{L}_\xi)}{\varepsilon}.
$$

Moreover, for the process $\partial_\mu V(t, \mu, X)$, we may introduce the path derivative $\partial_\omega \partial_\mu V$ in the spirit of Dupire [2009]. When $V$ is smooth enough in these senses, the functional Itô formula (4.7) below holds true. We refer to Wu and Zhang [2018] for details. In this section, to avoid the technical details, we take the approach in Ekren et al. [2016] and use the functional Itô formula directly to define the smoothness of $V$.

**Definition 4.3** Let $C^{1,2}(\Theta_T)$ denote the space of functions $V : \Theta_T \to \mathbb{R}$ such that there exist functions $\partial_\mu V : \Theta_T \times \Omega \to \mathbb{R}^d$ and $\partial_\omega \partial_\mu V : \Theta_T \times \Omega \to \mathbb{R}^{d \times d}$ satisfying:

(i) the $\partial_t V$ defined by (4.5) exists, and $V, \partial_t V, \partial_\mu V, \partial_\omega \partial_\mu V$ are all $\mathbb{F}$-adapted and uniformly continuous;

(ii) for any semimartingale measure $\mathbb{P}$, namely $X$ is a semimartingale under $\mathbb{P}$, the following functional Itô formula holds:

$$
dV(t, \mathbb{P}) = \partial_t V(t, \mathbb{P}) dt + \mathbb{E}^\mathbb{P} \left[ \partial_\mu V(t, \mathbb{P}, X) : dX_t + \frac{1}{2} \partial_\omega \partial_\mu V(t, \mathbb{P}, X) : d\langle X \rangle_t \right].
$$

By Lemma 2.7 and Wu and Zhang [2018], the spatial derivatives there coincide with the above $\partial_\mu V, \partial_\omega \partial_\mu V$ (with $\partial_\omega \partial_\mu V = \partial_\omega \omega \partial_\mu V$ in Markovian case). We remark that, for the purpose of viscosity solutions, in Wu and Zhang [2018], (4.7) is required only for semimartingale measures whose drift and diffusion characteristics are bounded. In that case, the regularity requirements on $V$ are weaker than the corresponding conditions in Lemma 2.7. It is not difficult to extend the functional Itô formula in Wu and Zhang [2018] to allow for more general semimartingale measures. Nevertheless, it is more convenient to define the derivatives through the functional Itô formula directly as we do here.

**Lemma 4.4** For any $V \in C^{1,2}(\Theta_T)$, the derivatives $\partial_\mu V$ and $\partial_\omega \partial_\mu V$ are unique in the sense that $\partial_\mu V(t, \mu, X)$ and $\frac{1}{2} \partial_\omega \partial_\mu V + (\partial_\omega \partial_\mu V)^\top(t, \mu, X)$ are $\mathbb{P}$-a.s. unique for any $(t, \mu) \in \Theta_T$.

We remark that, since $\langle X \rangle$ is symmetric, so the uniqueness of $\frac{1}{2} \partial_\omega \partial_\mu V + (\partial_\omega \partial_\mu V)^\top(t, \mu, X)$ implies that uniqueness of $\partial_\omega \partial_\mu V(t, \mathbb{P}, X) : d\langle X \rangle_t$ in (4.7).

**Proof.** First let $\mu \in \mathcal{P}_2(\mathcal{F}_T)$ be a semimartingale measure. For any $t \in [0, T]$ and any $\mathcal{F}_T$-measurable and bounded random variables $b_t$ and $\sigma_t > 0$, let $\mathbb{P} \in \mathcal{P}_2(\mathcal{F}_T)$ be such that

$$
\mathbb{P}_{[0,t]} = \mu_{[0,t]} \quad \text{and} \quad X_s - X_t = b_t[s - t] + \sigma_t[W_s - W_t], \quad t \leq s \leq T, \quad \mathbb{P}\text{-a.s.,}
$$

for some $\mathbb{P}$-Brownian motion $W$. Then, by (4.7), we see that

$$
\mathbb{E}^\mathbb{P} \left[ b_t : \int_t^s \partial_\mu V(r, \mathbb{P}, X) dr + \frac{1}{2} \sigma_t \sigma_t^\top : \int_t^s \partial_\omega \partial_\mu V(r, \mathbb{P}, X) dr \right]
$$
is unique. By the uniform continuity of $\partial_\mu V$ and $\partial_\eta \partial_\mu V$, this implies that
\[
\mathbb{E}^\mu \left[ b_t \cdot \partial_\mu V(t, \mu, X) + \frac{1}{2} \sigma_t \sigma_t^\top : \partial_\omega \partial_\mu V(t, \mu, X) \right]
\]
is unique. Here we rewrite $\mathbb{P}$ as $\mu$ since $\mathbb{P}_{[0,t]} = \mu_{[0,t]}$ and the integrand at above is $\mathcal{F}_t$-measurable. Since $b_t$ and $\sigma_t$ are arbitrary, we obtain the desired uniqueness.

Now assume $\mu \in \mathcal{P}_2(\mathcal{F}_T)$ is arbitrary. For any $\varepsilon > 0$, denote $X_\varepsilon^t := \frac{1}{\varepsilon} \int_{(t-\varepsilon)}^t X_s ds$ and $\mu^\varepsilon := \mu \circ (X^\varepsilon)^{-1}$. Then
\[
\mathcal{W}_2^2(\mu, \mu^\varepsilon) \leq \mathbb{E}^\mu \left[ ||X - X^\varepsilon||_2^2 \right] \to 0, \quad \text{as } \varepsilon \to 0,
\]
which implies that $\mu^\varepsilon \to \mu$ weakly. Clearly $X^\varepsilon$ is an $\mu$-semimartingale, then $\mu^\varepsilon$ is a semimartingale measure. Thus $\partial_\mu V(t, \mu^\varepsilon, X)$ is $\mu^\varepsilon$-a.s. unique. Let $\eta$ be $\mathcal{F}_t$-measurable, bounded, and continuous in $\omega$ (under $|| \cdot ||_T$). Note that, denoting by $\rho$ the modulus of continuity function of $\partial_\mu V$,
\[
\mathbb{E}^\mu \left[ \partial_\mu V(t, \mu^\varepsilon, X) \eta \right] - \mathbb{E}^\mu \left[ \partial_\mu V(t, \mu, X) \eta \right] \leq \mathbb{E}^\mu \left[ \partial_\mu V(t, \mu^\varepsilon, X) \eta \right] - \mathbb{E}^\mu \left[ \partial_\mu V(t, \mu, X) \eta \right] + \mathbb{E}^\mu \left[ \partial_\mu V(t, \mu^\varepsilon, X) \eta \right] - \mathbb{E}^\mu \left[ \partial_\mu V(t, \mu^\varepsilon, X) \eta \right]
= C(\rho(W_2(\mu, \mu^\varepsilon))) + \mathbb{E}^\mu \left[ \partial_\mu V(t, \mu^\varepsilon, X) \eta \right] - \mathbb{E}^\mu \left[ \partial_\mu V(t, \mu, X) \eta \right].
\]
Sending $\varepsilon \to 0$, by the weak convergence of $\mu^\varepsilon \to \mu$, we see that
\[
\mathbb{E}^\mu \left[ \partial_\mu V(t, \mu, X) \eta \right] = \lim_{\varepsilon \to 0} \mathbb{E}^\mu \left[ \partial_\mu V(t, \mu^\varepsilon, X) \eta \right]
\]
is unique. Since $\eta$ is arbitrary, we obtain the desired uniqueness of $\partial_\mu V(t, \mu, X)$. Similarly we have the uniqueness of $\partial_\eta \partial_\mu V$.

4.3 The control problem in weak formulation

Since the value function depends on the path of the state process $X$ anyway, we shall work on path-dependent setting directly, i.e. we will allow $b, \sigma, f, \mu$ and $g$ to depend on the paths of $X$, namely $b, \sigma, f$ are functions on $[0,T] \times \Omega \times A$ and $g$ is a function on $\Omega$, so as to have a more general result. Let $\mathcal{A}_t^\mu$ denote the set of $\mathbb{P}$-progressively measurable $\mu$-valued processes $\alpha$ on $[t,T]$ such that $\alpha_s = X_{(s-t)^+}$ measurable, namely $\alpha_s = \alpha_s(X_{(s-t)^+})$. Given $(t, \mu) \in \Theta_T$ and $\alpha \in \mathcal{A}_t^\mu$, denote by $\mathbb{P}^{t,\mu,\alpha}$ the unique probability measure $\mathbb{P} \in \mathcal{P}_2(\mathcal{F}_T)$ such that $\mathbb{P}_{[0,t]} = \mu_{[0,t]}$ and $\mathbb{P}$ is the strong solution of the following SDE on $[t,T]$: \[
dX_s = b(s, X_s, \alpha_s) ds + \sigma(s, X_s, \alpha_s) dW_s, \ t \leq s \leq T, \mathbb{P} \text{-a.s.} \] (4.8)
We emphasize again that at above $\alpha_s = \alpha_s(X_{(s-t)^+})$. We then define
\[
V(t, \mu) := \sup_{\alpha \in \mathcal{A}_t^\mu} J(t, \mu, \alpha) := \sup_{\alpha \in \mathcal{A}_t^\mu} \mathbb{E}^{\mu,\alpha}_{t} \left[ g(X_T) + \int_t^T f(s, X_s, \alpha_s) ds \right]. \] (4.9)

Remark 4.5 When $T \leq h, \alpha_t$ is $\mathcal{F}_0$-measurable for $t \in [0,T]$. Since $\mathcal{F}_0$ is not degenerate here, so in general $\alpha$ may not be deterministic, and thus rigorously speaking the formulation here is slightly different from that in Sections 2 and 3. However, they are equivalent when $\mu_0$ is degenerate, namely $X_0$ is a constant, $\mu$-a.s.

Alternatively, following the rationale of information delay, one may require $\alpha_t$ to be $\mathcal{F}_{0-} := \{\emptyset, \Omega\}$-measurable for $t < h$, and thus is deterministic. One minor disadvantage of this reformulation is that the information flow will have a jump at $t = h$. Again, this discontinuity disappears when $\mu_0$ is degenerate.
Similar to Assumption 2.1, we shall assume:

**Assumption 4.6** (i) \( b, \sigma, f \) are \( \mathbb{F} \)-adapted, and \( b(t, 0, a), \sigma(t, 0, a), \) and \( f(t, 0, a) \) are bounded;
(ii) \( b \) and \( \sigma \) are uniformly Lipschitz continuous in \( \omega \), uniformly continuous in \( t \), and continuous in \( a \);
(iii) \( f \) is uniformly continuous in \( (t, \omega) \) and continuous in \( a \), and \( g \) is uniformly continuous in \( \omega \).

Under the above assumptions, it is clear that (4.8) is wellposed, \( V \) is \( \mathbb{F} \)-adapted, and analogous to Theorem 2.3 one can easily prove

\[
V(t, \mu) = \sup_{\alpha \in A^t} \left[ V(t + \delta, \mathbb{P}^{t, \mu, \alpha}) + \int_t^{t + \delta} \mathbb{E}^{p, \mu, \alpha} [f(s, X_s, \alpha_s)] \, ds \right]. \tag{4.10}
\]

Now assume \( V \in C^{1,2}(\Theta_T) \) in the sense of Definition 4.3. By (4.10), similar to Theorem 2.8 one can easily derive

\[
\partial_t V(t, \mu) + H(t, \mu, \partial_t V, \partial_x \partial_t V) = 0, \tag{4.11}
\]

where, for \( p : \Theta_T \times \Omega \to \mathbb{R}^d \) and \( q : \Theta_T \times \Omega \to \mathbb{R}^{d \times d} \),

\[
H(t, \mu, p, q) := \sup_{\alpha \in A^t} h(t, \mu, p, q, \alpha_t), \quad h(t, \mu, p, q, \alpha_t) := \mathbb{E}^\mu \left[ b(\cdot) \cdot p(t, \mu, X) + \frac{1}{2} \sigma \sigma^\top(\cdot) : q(t, \mu, X) + f(\cdot) \right](t, \alpha_t). \tag{4.12}
\]

Note that \( \alpha_t \) is \( \mathcal{F}_{(t-h)} \)-measurable. Denote \( \mathcal{T} := (t - H)^+ \) and let \( \mu^{\mathcal{T}} \omega \) denote the regular conditional probability distribution of \( \mu \) given \( \mathcal{F}_\mathcal{T} \), i.e. \( \mu^{\mathcal{T}} \omega(E) = \mathbb{E}^\mu[1_{E}(X_{\mathcal{T}, \omega}) | \mathcal{F}_\mathcal{T}(\omega)] \) for \( \mu \)-a.e. \( \omega \in \Omega \). Then,

\[
h(t, \mu, p, q, \alpha_t) := \mathbb{E}^\mu \left[ \mathcal{H}(t, X_{\mathcal{T}, \omega}, \mu, p, q, \alpha_t(X_{\mathcal{T}, \omega})) \right], \quad \text{where}
\]

\[
\mathcal{H}(t, \omega, \mu, p, q, a) := \mathbb{E}^{\mu^{\mathcal{T}} \omega} \left[ b(\cdot) \cdot p(t, \mu, X) + \frac{1}{2} \sigma \sigma^\top(\cdot) : q(t, \mu, X) + f(\cdot) \right](t, \alpha_t). \tag{4.13}
\]

We remark that in (4.12) \( h \) depends on the whole random variable \( \alpha_t \), while in (4.13) \( \mathcal{H} \) depends on the realized value \( a \in A \). We have the following result:

**Theorem 4.7** Let Assumption 4.6 hold.

(i) For any \( p : \Theta_T \times \mathbb{R}^d \to \mathbb{R}^d, q : \Theta_T \times \mathbb{R}^d \to \mathbb{R}^{d \times d} \) uniformly continuous, the Hamiltonian \( H \) in (4.12) becomes

\[
H(t, \mu, p, q) = \mathbb{E}^\mu \left[ \sup_{\alpha \in A} \mathcal{H}(t, X_{\mathcal{T}, \omega}, \mu, p, q, a) \right]. \tag{4.14}
\]

(ii) Assume \( V \in C^{1,2}(\Theta_T) \). Then \( V \) is the value function in (4.9) if and only if \( V \) satisfies the following path-dependent master equation:

\[
\partial_t V(t, \mu) + \mathbb{E}^\mu \left[ \sup_{\alpha \in A} \mathcal{H}(t, X_{\mathcal{T}, \omega}, \mu, \partial_t V, \partial_x \partial_t V, \alpha) \right] = 0, \quad V(T, \mu) = \mathbb{E}^\mu[g(X_T)]. \tag{4.15}
\]

**Proof.** (i) Define

\[
\tilde{H}(t, \mu, p, q) := \mathbb{E}^\mu \left[ \sup_{a \in A} \mathcal{H}(t, X_{\mathcal{T}, \omega}, \mu, p, q, a) \right].
\]

It is clear that \( H \leq \tilde{H} \). To see the opposite inequality, fix \((t, \mu, p, q)\) as specified in (i). By our conditions, it is obvious that \( \omega \mapsto \mathcal{H}(t, \omega, \mu, p, q, a) \) is \( \mathcal{F}_\mathcal{T} \)-measurable for each \( a \), and \( a \mapsto \mathcal{H}(t, \omega, \mu, p, q, a) \) is continuous for each \( \omega \). Then \((\omega, a) \mapsto \mathcal{H}(t, \omega, \mu, p, q, a) \) is \( \mathcal{F}_\mathcal{T} \times \mathcal{B}(A) \)-measurable. By the standard measurable
selection theorem, see e.g. [El Karoui and Tan, 2013, Proposition 2.21], for any \( \varepsilon > 0 \), there exists an \( \mathcal{F}_t^{\varepsilon} \)-measurable random variable \( a^\varepsilon \) such that

\[
\tilde{H}(t, X_{[0,t]}, \mu, p, q, a^\varepsilon) \geq \sup_{\alpha \in A} \tilde{H}(t, X_{[0,t]}, \mu, p, q, \alpha) - \varepsilon, \quad \mu\text{-a.s.,}
\]

where \( \mathcal{F}_t^{\varepsilon} \) denotes the \( \mu \)-augmentation of \( \mathcal{F}_t \). By [Zhang, 2017, Proposition 1.2.2], there exists \( \mathcal{F}_t \)-measurable \( \alpha_t^\varepsilon \) such that \( \alpha_t^\varepsilon = a^\varepsilon, \mu\text{-a.s.} \). Then

\[
\tilde{H}(t, \mu, p, q) \leq \mathbb{E}^\mu [\tilde{H}(t, X_{[0,t]}, \mu, p, q, \alpha_t^\varepsilon)] + \varepsilon \leq H(t, \mu, p, q) + \varepsilon.
\]

By the arbitrariness of \( \varepsilon \), we obtain \( \tilde{H} \leq H \), and thus the equality holds.

(ii) follows from similar arguments as in Theorem 2.8.

Assume further that the following Hamiltonian \( \overline{H} \) has an optimal argument \( a^* \):

\[
\overline{H}(t, \omega, \mu, \partial_p V, \partial_\omega V, \partial_\mu V, a) := \sup_{\alpha \in A} \tilde{H}(t, \omega, \mu, \partial_p V, \partial_\omega V, \partial_\mu V, a).
\]  

(4.16)

By (4.13), we see that \( a^* \) takes the form \( I(t, \mu^{\omega}, \omega_{[0,t]}) \). Then (4.8) becomes a McKean-Vlasov SDE again:

\[
dX^*_s = b(s, X^*_s, I(s, \mathbb{P}^*, X^*_s, \omega_{[0,t]}))ds + \sigma(s, X^*_s, I(s, \mathbb{P}^*, X^*_s, \omega_{[0,t]}))dW_s, \mathbb{P}\text{-a.s.}
\]

(4.17)

Similar to Theorem 2.10, one can easily prove:

**Theorem 4.8** Let Assumption 4.6 hold and \( V \in C^{1,2}(\Theta_T) \) be the classical solution to the master equation (4.15). Assume further that

(i) the Hamiltonian \( \overline{H} \) defined by (4.16) has an optimal control \( a^* = I(t, \mu^{\omega}, \omega_{[0,t]}), \) for any \( (t, \mu) \in \Theta_T \), where \( I : \Theta_T \times \Omega \to A \) is measurable;

(ii) for a fixed \( (t, \mu) \in \Theta_T \), the McKean-Vlasov SDE (4.17) on \([t,T]\) has a (strong) solution \( \mathbb{P}^* \) such that \( \mathbb{P}^*_{[0,t]} = \mu_{[0,t]} \).

Then \( \alpha^*_s := I(s, (\mathbb{P}^*)^{\omega}, \omega_{[0,t]}), \) \( s \in [t,T] \), is an optimal control for the optimization problem (4.9) with this fixed \( (t, \mu) \).

It will be interesting to extend Theorems 2.11 and 3.1 to this case. This requires the measurability and/or regularity in terms of the paths and is more challenging. We shall leave a more systematic study on these issues in future research. In the subsection below, we shall solve the linear quadratic case which extends the example in Subsection 3.1.

Finally, consider a special case where \( b, \sigma, f \) do not depend on \( X \). Then

\[
\overline{H}(t, \omega, \mu, p, q, a) = \frac{1}{2} \sigma \sigma^\top (t, a) \cdot \mathbb{E}^\mu [g(t, \mu, X_t)|\mathcal{F}_t] + b(t, a) \cdot \mathbb{E}^\mu [p(t, \mu, X_t)|\mathcal{F}_t] + f(t, a),
\]

thus \( a^* \) takes the form: \( a^* = I(t, \mathbb{E}^\mu [p(t, \mu, X_t)|\mathcal{F}_t], \mathbb{E}^\mu [g(t, \mu, X_t)|\mathcal{F}_t]) \). Therefore, (4.17) becomes:

\[
\begin{align*}
\frac{dX^*_s}{ds} & = b(s, X^*_s, I(s, \mathbb{E}[\partial_p V|\mathcal{F}_s], \mathbb{E}[\partial_\omega V|\mathcal{F}_s]) ds \\
& + \sigma(s, X^*_s, I(s, \mathbb{E}[\partial_p V|\mathcal{F}_s], \mathbb{E}[\partial_\omega V|\mathcal{F}_s]) )dW_s, \quad \mathbb{P}\text{-a.s.}
\end{align*}
\]

(4.18)

where \( \partial_p V \) and \( \partial_\omega \partial_p V \) are computed at \( (s, \mathcal{L}_{X^*_s:[0,t]}, X_s) \).
4.4 The linear-quadratic example

Consider the path-dependent setting of the example in Section 3:

\[ d = 1, \ A = \mathbb{R}, \ b(t, x, a) = a, \ \sigma = 1, \ f(t, x, a) = -\frac{1}{2}a^2, \ g(x) = x^2, \ T = 2h. \]  

(4.19)

In this case (4.11) becomes: recalling \( \overline{\mathcal{T}} := (t - h)^+ \),

\[
\partial_t V(t, \mu) + \frac{1}{2} \mathbb{E}^\mu \left( \partial_{\mu} \partial_{\mu} V(t, \mu, X) \right) + \frac{1}{2} \mathbb{E}^\mu \left[ \mathbb{E}^\mu \left( \partial_{\mu} V(t, \mu, X) \right) | \mathcal{F}_T \right]^2 = 0, 
\]

(4.20)

Moreover, provided (4.20) has a classical solution, then (4.18) reduces to:

\[ dX^*_s = \mathbb{E}\left[ \partial_{\mu} V(s, \mathbb{E}^*, X_s) | \mathcal{F}_s \right] ds + dW_s, \quad \mathbb{P}\text{-a.s.} \]

(4.21)

We shall show that (4.20) has a classical solution \( V \) and that it is indeed path-dependent.

**Theorem 4.9** Let (4.19) hold. Assume \( h < \frac{1}{4} \) and denote \( \overline{\mathcal{T}} := \frac{1}{2} - h \).

(i) The \( V \) defined by (4.9) is equal to

\[
V(t, \mu) = \begin{cases} 
   \mathbb{E}^\mu \left[ |X_t|^2 \right] + \frac{1}{2} \int_{t-h}^t \mathbb{E}^\mu \left[ |X_s|^2 \right] ds + T - t, & t \in [h, 2h]; \\
   \frac{\mathbb{E}^\mu \left[ |X_t|^2 \right]}{2(\overline{\mathcal{T}} + t)} + \frac{1}{2} \mathbb{E}^\mu \left[ \mathbb{E}^\mu \left[ |X_t|^2 \right] | \mathcal{F}_s \right] ds + h + \frac{1}{2} \ln \frac{1}{\overline{\mathcal{T}} + t}, & t \in [0, h]. 
\end{cases} 
\]

(4.22)

It is in \( C^{1,2}(\overline{\mathcal{T}}) \) and is a classical solution to the path-dependent master equation (4.20);

(ii) For any \( (t, \mu) \in \overline{\mathcal{T}}, \) the SDE (4.21) on \([t, T]\) with initial condition \( \mathbb{P} \circ (X^*_{[0,t]})^{-1} = \mu_{[0,t]} \) has a strong solution \( X^* \), and the optimal control takes the form:

\[
\alpha^*_s = \mathbb{E}^\mu \left[ \partial_{\mu} V(s, \mathbb{E}^*, X_s) | \mathcal{F}_s \right], \quad \mathbb{P}^* = \mathbb{P} \circ (X^*)^{-1}. 
\]

(4.23)

**Proof.** We proceed in several steps. Recall that \( \overline{\mathcal{T}} := (t - h)^+ \).

Step 1. We first prove (4.22) for \( t \in [h, 2h] \). Let \( \mu \in \mathcal{P}_2(\mathcal{F}_t), \ \alpha \in \mathcal{A}_t \). Denote \( \beta^* := \alpha^{s \mapsto h}, s \in [0, h] \). Then \( \beta \) is \( \mathbb{F} \)-progressively measurable. Denote by \( \mu \otimes \mathbb{P}_0 \) the probability measure \( \mathbb{P} \) such that \( \mathbb{P}_{[0,t]} = \mu_{[0,t]} \) and \( X_s = X_t + W_s - W_t, \mathbb{P}\text{-a.s.} \) for a \( \mathbb{P} \)-Brownian motion \( W \). By (4.8) and (4.9) one can easily see that

\[
J(t, \mu, \alpha) = \mathbb{E}^{\mu \otimes \mathbb{P}_0} \left[ \left( X_t + \int_t^h \beta^*_s dr + W_t - W_t \right)^2 - \frac{1}{2} \int_t^h \beta^*_s dr \right] 
\]

\[
= \mathbb{E}^{\mu} \left[ \left( X_t + \int_t^h \beta^*_s dr \right)^2 - \frac{1}{2} \int_t^h \beta^*_s dr \right] + T - t. 
\]

(4.24)

Since \( h < \frac{1}{4} \) and \( \beta \) is \( \mathbb{F} \)-progressively measurable, one can easily show that the optimal \( \beta^* \) is the unique fixed point satisfying:

\[
\beta^*_s = 2 \mathbb{E}^{\mu} \left[ X_t + \int_t^\tau \beta^*_r dr \right], \quad \tau \leq s \leq h. 
\]

This implies that \( \beta^* \) is a \( \mu \)-martingale. Then

\[
\beta^*_s = 2 \mathbb{E}^{\mu} \left[ X_t + \int_0^s \beta^*_r dr + 2[H - s] \beta^*_s \right]. 
\]
Solving this ODE, we obtain:

\[ \beta_s^* = \int_T^s \frac{\mathbb{E}_\mu [X_t]}{H + r} dr + \frac{\mathbb{E}_\mu [X_t]}{H + s}. \] (4.25)

Then by (4.9) and (4.24) we have

\[ V(t, \mu) = \mathbb{E}_\mu \left[ |X_t| + \int_T^t \beta_s^* ds \right]^2 - \frac{1}{2} \int_T^t |\beta_s^*|^2 ds \] + T - t. \] (4.26)

Note that (4.25) implies

\[ \int_T^s \beta_s^* dr = (H + s) \int_T^s \frac{\mathbb{E}_\mu [X_t]}{(H + r)^2} dr, \] (4.27)

and thus

\[
\mathbb{E}_\mu \left[ |X_t| + \int_T^t \beta_s^* ds \right]^2 = \mathbb{E}_\mu \left[ |X_t| + \int_T^t \frac{\mathbb{E}_\mu [X_t]}{2(H + r)^2} ds \right]^2 \\
= \mathbb{E}_\mu \left[ |X_t|^2 + X_t \int_T^t \frac{\mathbb{E}_\mu [X_t]}{H + s} ds + \int_T^t \frac{\mathbb{E}_\mu [X_t]}{2(H + s)^2} ds \right]^2 \\
= \mathbb{E}_\mu \left[ |X_t|^2 + \int_T^t \frac{\mathbb{E}_\mu [X_t]^2}{2(H + s)^2} ds + \int_T^t \frac{\mathbb{E}_\mu [X_t]^2}{2(H + r)^2 dr ds} \right] \\
= \mathbb{E}_\mu \left[ |X_t|^2 + \int_T^t \frac{\mathbb{E}_\mu [X_t]^2}{2(H + s)^3} ds \right].
\]

Moreover, note that

\[
\mathbb{E}_\mu [|\beta_s^*|^2] = \mathbb{E}_\mu \left[ \frac{\mathbb{E}_\mu [X_t]}{H + s} \right]^2 + \frac{2\mathbb{E}_\mu [X_t]}{H + s} \int_T^T \frac{\mathbb{E}_\mu [X_t]}{H + r}^2 dr + \frac{\mathbb{E}_\mu [X_t]}{H + r} \int_T^t \frac{\mathbb{E}_\mu [X_t]}{(H + r)^2} dr \\
= \mathbb{E}_\mu \left[ \frac{\mathbb{E}_\mu [X_t]}{H + s} \right]^2 + \frac{2\mathbb{E}_\mu [X_t]}{H + s} \int_T^T \frac{\mathbb{E}_\mu [X_t]}{(H + r)^3} dr + \frac{\mathbb{E}_\mu [X_t]}{(H + r)^2} \int_T^t \frac{\mathbb{E}_\mu [X_t]}{(H + r)^2} \left[ \frac{1}{H + r} - \frac{1}{H + s} \right] dr \\
= \mathbb{E}_\mu \left[ \frac{\mathbb{E}_\mu [X_t]}{H + s} \right]^2 + 2 \int_T^T \frac{\mathbb{E}_\mu [X_t]}{(H + r)^3} dr,
\]

and thus

\[
\mathbb{E}_\mu \left[ \int_T^t |\beta_s^*|^2 ds \right] = \mathbb{E}_\mu \left[ \int_T^T \frac{\mathbb{E}_\mu [X_t]}{H + s}^2 ds + 2 \int_T^T \frac{(H - s)|\mathbb{E}_\mu [X_t]|^2}{(H + s)^3} ds \right] \\
= \mathbb{E}_\mu \left[ \int_T^T \frac{\mathbb{E}_\mu [X_t]}{(H + s)^3} ds \right].
\]

Plug these into (4.26), we obtain

\[ V(t, \mu) = \mathbb{E}_\mu \left[ |X_t|^2 + \int_T^t \frac{\mathbb{E}_\mu [X_t]^2}{2(H + r)^3} ds - \int_T^t \frac{(H + s)|\mathbb{E}_\mu [X_t]|^2}{2(H + s)^3} ds \right] + T - t, \]

which implies the first equality of (4.22) immediately.

**Step 2.** We next prove (4.22) for \( t < H \). Set \( t = H \) in Step 1, we have

\[ V(H, \mu) = \mathbb{E}_\mu \left[ |X_H|^2 + \int_0^H \frac{\mathbb{E}_\mu [X_H]^2}{2(H + s)^3} ds \right] + H. \]
Fix \( \mu \in \mathcal{P}_2(\mathcal{F}_T) \) and recall \( \mu \otimes_t \mathbb{P}_0 \). Note that \( \alpha \in \mathcal{A}^\mu_t \) is \( \mathcal{F}_0 \)-measurable. Then,

\[
V(\mathbb{H}, \mathbb{P}^{t, \mu, \alpha}) = \mathbb{E}^{\mu \otimes \mathbb{P}_0} \left[ |X_t + \int_t^H \alpha_r dr + W_H| - W_t^2 \right] + \int_0^H \mathbb{E}^{\mu \otimes \mathbb{P}_0} \left[ |X_t + \int_t^H \alpha_r dr + W_H| - W_t^2 \right] ds + H
\]

\[
= \mathbb{E}^{\mu} \left[ |X_t + \int_t^H \alpha_r dr|^2 \right] + 2H - t
\]

\[
+ \mathbb{E}^{\mu} \left[ \int_0^t \mathbb{E}^{\mu} \left[ |X_t + \int_t^H \alpha_r dr|^2 \right] ds + \int_t^H |X_t + \int_t^H \alpha_r dr|^2 + s - t ds \right]
\]

\[
= \Gamma_t + \frac{1}{2H} \mathbb{E}^{\mu} \left[ 2\mathbb{E}^{\mu}_0 [X_t] \int_t^H \alpha_r dr + | \int_t^H \alpha_r dr |^2 - H \int_t^H |\alpha_r|^2 ds \right].
\]

where \( \Gamma_t := \frac{\mathbb{E}^{\mu} \|X_t\|^2}{2(H + t)} + \int_t^H \mathbb{E}^{\mu} \|X_t\|^2 ds + H + \frac{1}{2} \ln \frac{1}{2(H + t)} \).

By the DPP (4.10), we have

\[
V(t, \mu) = \sup_{\alpha \in \mathcal{A}^\mu} \left[ V(\mathbb{H}, \mathbb{P}^{t, \mu, \alpha}) - \frac{1}{2} \int_t^H \mathbb{E}^{\mu} [\alpha_r^2] ds \right]
\]

\[
= \Gamma_t + \sup_{\alpha \in \mathcal{A}^\mu} \frac{1}{2H} \mathbb{E}^{\mu} \left[ 2\mathbb{E}^{\mu}_0 [X_t] \int_t^H \alpha_r dr + | \int_t^H \alpha_r dr |^2 - H \int_t^H |\alpha_r|^2 ds \right].
\]

One can easily see that the optimal \( \alpha^* \) satisfies:

\[
\mathbb{E}^{\mu}_0 [X_t] + \int_t^H \alpha_r^* dr = \mathbb{H} \alpha^*_r.
\]

This implies

\[
\alpha^*_r = c_t := \frac{\mathbb{E}^{\mu}_0 [X_t]}{H + t}, \quad t \leq s \leq H,
\]

and thus

\[
V(t, \mu) = \Gamma_t + \frac{1}{2H} \mathbb{E}^{\mu} \left[ 2\mathbb{E}^{\mu}_0 [X_t] \int_t^H \alpha_r^* dr + | \int_t^H \alpha_r^* dr |^2 - H \int_t^H |\alpha_r^*|^2 ds \right].
\]

which implies the second equality of (4.22) immediately.

**Step 3.** We now verify that \( V \in C^{1,2}(\Theta_T) \) and satisfies (4.20). First consider \( t \in [H, 2H] \). By (4.22) one may verify straightforwardly that

\[
\partial_t V(t, \mu) = - \frac{\mathbb{E}^{\mu} \|X_t\|^2}{2(H + t)} - 1.
\]

To see \( \partial_\mu V \), we remark that the \( V \) in (4.22) is very smooth and actually one can use the stronger definition in the sprit of (4.6) instead of Definition 4.3. We will again refer to Wu and Zhang (2018) for details and will derive \( \partial_\mu V \) formally. Given a random variable \( X_t^\prime \in L^2(\mathcal{F}_T) \), in the sprit of (4.6) we have

\[
\mathbb{E} \left[ \partial_\mu V(t, \mu, X) X_t^\prime \right] = \mathbb{E}^{\mu} \left[ 2X_t^\prime X_t + \int_t^H \mathbb{E}^{\mu}_0 [X_t] \mathbb{E}^{\mu}_0 [X_t^\prime] ds \right]
\]

\[
= \mathbb{E}^{\mu} \left[ 2X_t + \int_t^H \mathbb{E}^{\mu}_0 [X_t] ds \right] X_t^\prime.
\]
Then

$$
\partial_\mu V(t, \mu, X) = 2X_t + \int_T^t \frac{\mathbb{E}_\mu^t[X_s]}{(\omega + s)^2} ds.
$$

(4.30)

Moreover, note that \( \int_T^t \frac{\mathbb{E}_\mu^t[X_s]}{(\omega + s)^2} ds \) is \( \mathcal{F}_t \)-measurable and \( H \leq t \), then its path derivative with respect to \( \omega \) is 0, and thus

$$
\partial_\omega \partial_\mu V(t, \mu, X) = 2.
$$

(4.31)

Note that, by (4.30),

$$
\mathbb{E}_\mu^t[\partial_\mu V(t, \mu, X)] = \mathbb{E}_\mu^t[X_t] \left[ 2 + \int_T^t \frac{1}{(\omega + s)^2} ds \right] = \frac{\mathbb{E}_\mu^t[X_t]}{\mu + t}.
$$

Then

$$
\partial_t V(t, \mu) + \frac{1}{2} \mathbb{E}_\mu^t \left[ \partial_\mu^2 V(t, \mu, X) \right] + \frac{1}{2} \mathbb{E}_\mu^t \left[ \mathbb{E}_\mu^t \left[ \partial_\mu V(t, \mu, X) \right] \right]^2 = 0.
$$

(4.32)

That is, \( V \) satisfies (4.20) for \( t \in [H, 2H] \).

Next consider \( t \in [0, H] \). By (4.22) one may verify directly that

$$
\partial_t V(t, \mu) = -\frac{\mathbb{E}_\mu^t[X_t^2]}{2(H + t)^2} - \frac{1}{2} \mathbb{E}_\mu^t \left[ \mathbb{E}_\mu^t \left[ \partial_\mu V(t, \mu, X) \right] \right]^2
$$

$$
\partial_\mu V(t, \mu, X) = \frac{X_t}{\mu + t} + \int_0^t \frac{\mathbb{E}_\mu^t[X_s]}{(\omega + s)^2} ds + \frac{(H - t)\mathbb{E}_\mu^t[X_t]}{\mu(H + t)};
$$

$$
\partial_\omega \partial_\mu V(t, \mu, X) = \frac{1}{\mu + t}.
$$

Note that

$$
\mathbb{E}_\mu^t \left[ \partial_\mu V(t, \mu, X) \right] = \frac{\mathbb{E}_\mu^t[X_t]}{H + t} + \int_0^t \frac{\mathbb{E}_\mu^t[X_s]}{(\omega + s)^2} ds + \frac{(H - t)\mathbb{E}_\mu^t[X_t]}{H(H + t)} = \frac{\mathbb{E}_\mu^t[X_t]}{H + t}.
$$

Therefore,

$$
\partial_t V(t, \mu) + \frac{1}{2} \mathbb{E}_\mu^t \left[ \partial_\mu^2 V(t, \mu, X) \right] + \frac{1}{2} \mathbb{E}_\mu^t \left[ \mathbb{E}_\mu^t \left[ \partial_\mu V(t, \mu, X) \right] \right]^2
$$

$$
= -\frac{\mathbb{E}_\mu^t[X_t^2]}{2(H + t)^2} - \frac{1}{2} \mathbb{E}_\mu^t \left[ \mathbb{E}_\mu^t \left[ \partial_\mu V(t, \mu, X) \right] \right]^2 = 0.
$$

That is, \( V \) is a classical solution to (4.20) on \([0, H]\) as well.

**Step 4.** Finally, we prove (ii). Note that in this case (4.21) can be rewritten as:

$$
dx^*_s = \alpha^*_s ds + dW_s.
$$

(4.32)

If \( t \geq H \), the optimal control is \( \alpha^*_s = \beta^*_s \) for the \( \beta^* \) defined by (4.25):

$$
\alpha^*_s = \int_T^s \frac{\mathbb{E}_\mu^t[X_s]}{(\omega + r)^2} dr + \frac{\mathbb{E}_\mu^t[X_s]}{\mu + r}, \quad t \leq s \leq 2H.
$$

(4.33)
The optimal control and the optimal state process are: noting that

\[ X_s^* = X_t + \left[ H + \mathbb{E} \right] \int_t^s \frac{\mathbb{E}_r^\mu[X_r]}{(\mathbb{H} + r)^2} dr + W_s - W_t, \quad t \leq s \leq 2H. \]  

(4.34)

Now assume \( t < H \). For \( s \in [t, H] \), we have \( \alpha^*_s = c_t \), where \( c_t \) is defined by (4.28). For \( s \in (H, 2H] \), the optimal \( \alpha^* \) is obtained through the optimization problem \( V(H, \mathbb{P}^{t, \mu, c_t}) \). By using (4.25), (4.27), (4.32), it follows from direct calculation that

\[
X_s^* = \left\{
\begin{array}{ll}
X_t + c_t[s - t] + W_s - W_t, & t \leq s \leq H; \\
X_t^H + (H + \mathbb{E}) \int_0^s \frac{\mathbb{E}_r^\mu[X_r] + c_t[H - t]}{(H + r)^2} dr + W_s - W_t^H, & H < s \leq t + H; \\
X_t^H + (H + \mathbb{E}) \left[ \int_0^t \frac{\mathbb{E}_r^\mu[X_r] + c_t[H - t]}{(H + r)^2} dr + \int_t^s X_r^* + c_t[H - r] \frac{dr}{(H + r)^2} \right] + W_s - W_t^H, & t + H < s \leq 2H;
\end{array}\right.
\]

(4.35)

\[
\alpha_s^* = \left\{
\begin{array}{ll}
\frac{\mathbb{E}_r^\mu[X_r] + c_t[H - t]}{H + \mathbb{E}} + \int_0^r \frac{\mathbb{E}_r^\mu[X_r] + c_t[H - t]}{(H + r)^2} dr, & H < s \leq t + H; \\
\frac{X_t^H + c_t[2H - s]}{H + \mathbb{E}} + \int_0^t \frac{\mathbb{E}_r^\mu[X_r] + c_t[H - t]}{(H + r)^2} dr + \int_t^s X_r^* + c_t[H - r] \frac{dr}{(H + r)^2}, & t + H < s \leq 2H.
\end{array}\right.
\]

(4.36)

This completes the proof.

**Remark 4.10** Consider the special case with \( t = 0 \) and \( \mu = \delta_{x_0} \).

(i) By the above results, we have

\[
V_0 = V(0, \delta_{x_0}) = \frac{x_0^2}{2H} + H + \frac{1}{2} \ln \left( \frac{1}{2H} \right) + \frac{H}{2H(\frac{1}{2} - 2H)} x_0^2
\]

(4.37)

\[ = \frac{x_0^2}{1 - 4H} + H - \frac{1}{2} \ln(1 - 2H). \]

The optimal control and the optimal state process are: noting that \( c_0 = \frac{x_0}{1 - 2H} \),

\[
\alpha_s^* = \left\{
\begin{array}{ll}
c_0, & 0 \leq s \leq H; \\
X_{s-H} + c_0[2H - s] \frac{X_r + c_0(H - r)}{(H + r)^2} dr, & H < s \leq 2H.
\end{array}\right.
\]

(4.38)

\[
X_s^* = \left\{
\begin{array}{ll}
x_0 + c_0s + W_s, & 0 \leq s \leq H; \\
X_t^H + (H + \mathbb{E}) \int_0^s X_r^* + c_0[H - r] \frac{dr}{(H + r)^2} + W_s - W_t^H, & H < s \leq 2H.
\end{array}\right.
\]

(4.39)
(ii) If the delay time is $2h$ (and $T$ is still $2t$), namely considering only deterministic controls $\alpha$, then

$$J(0, x_0, \alpha) = E^{\mathbb{P}_0} \left[ |x_0 + \int_0^T \alpha_s ds + W_T|^2 - \frac{1}{2} \int_0^T |\alpha_s|^2 ds \right]$$

$$= |x_0 + \int_0^T \alpha_s ds|^2 + T - \frac{1}{2} \int_0^T |\alpha_s|^2 ds.$$  

One can easily show that the optimal control and optimal values are, using superscript $2h$ to denote the delay time and recalling $T = 2h$,

$$\alpha_2^{2h} = \frac{2x_0}{1 - 4h}, \quad V_2^{2h} = \frac{x_0^2}{1 - 4h} + 2h. \quad (4.40)$$

(iii) If the delay time is 0, then we have a standard HJB equation:

$$\partial_t v(t, x) + \frac{1}{2} \partial_{xx} v + \frac{1}{2} |\partial_x v|^2 = 0, \quad v(T, x) = |x|^2.$$  

One can easily see that the above PDE has a classical solution

$$v(t, x) = \frac{x^2}{1 - 2T + 2t} - \frac{1}{2} \ln(1 - 2T + 2t).$$

This implies that, using superscript 0 to denote the delay time 0 and recalling $T = 2h$,

$$\alpha^0(s, x) = \partial_x v(t, x) = \frac{2x}{1 - 4h + 2t}, \quad V_0^0 = v(0, x_0) = \frac{x_0^2}{1 - 4h} - \frac{1}{2} \ln(1 - 4h). \quad (4.41)$$

(iv) One can verify straightforwardly that, for $0 < h < \frac{1}{4}$,

$$2h < h - \frac{1}{2} \ln(1 - 2h) < -\frac{1}{2} \ln(1 - 4h), \quad \text{which implies } V_0^{2h} < V_0 < V_0^0.$$  

This indicates that the information delay indeed decreases the value function, consistent with our intuition. \[\square\]

### A

In this appendix, we show heuristically how the stochastic maximum principle leads to the same structure as in Section 2. We remark that this approach has also been used by Hu and Tang [2017] recently for a mixture of deterministic and stochastic controls in a linear quadratic setting. To focus on the main idea and simplify the presentation, we consider the following simple case with deterministic controls $\alpha \in \mathcal{A}$:

$$V_0 := \sup_{\alpha \in \mathcal{A}} J(\alpha) := \sup_{\alpha \in \mathcal{A}} E \left[ g(X_T^\alpha) + \int_0^T f(t, \alpha_t) dt \right],$$

where $X_T^\alpha = x + \int_0^t b(s, \alpha_s) ds + W_t$, \quad (A.1)

where $\mathcal{A}$ is the set of all Borel measurable functions $\alpha : [0, T] \to A$.

Since $\mathcal{A}$ is convex, namely, for $\alpha, \alpha' \in \mathcal{A}$, we have $\alpha + \epsilon(\alpha' - \alpha) \in \mathcal{A}$ for all $\epsilon \in (0, 1)$. Fix $\alpha, \alpha' \in \mathcal{A}$ and denote $\Delta \alpha := \alpha' - \alpha$, $\alpha^\varepsilon := \alpha + \varepsilon \Delta \alpha$. Assume $b$ and $f$ are continuous differentiable in $a$ and $g$ is continuously differentiable in $x$. Then

$$\nabla X_t := \lim_{\varepsilon \to 0} \frac{X_t^{\alpha' \varepsilon} - X_t^{\alpha}}{\varepsilon} = \int_0^t \partial_b b(s, \alpha_s) \Delta \alpha_s ds,$$

$$\nabla J := \lim_{\varepsilon \to 0} \frac{J(\alpha^\varepsilon) - J(\alpha)}{\varepsilon} = E \left[ \partial_a g(X_T^\alpha) \nabla X_T + \int_0^T \partial_a f(s, \alpha_s) \Delta \alpha_s ds \right].$$

24
Let \((\tilde{Y}^\alpha, \tilde{Z}^\alpha)\) be the solution to the following BSDE:

\[
\tilde{Y}^\alpha_t = \partial_x g(X^\alpha_T) - \int_t^T \tilde{Z}^\alpha_s dW_s.
\]

We emphasize that \((\tilde{Y}^\alpha, \tilde{Z}^\alpha)\) depend on \(\alpha\), but not on \(\Delta \alpha\). Then

\[
\nabla J = \mathbb{E} \left[ \int_t^T \tilde{Y}^\alpha_s \partial_b(s, \alpha_s) + \partial_a f(s, \alpha_s) \Delta \alpha_s ds \right]
= \int_t^T \mathbb{E} [\tilde{Y}^\alpha_s] \partial_b(s, \alpha_s) + \partial_a f(s, \alpha_s) \Delta \alpha_s ds,
\]

where the second equality relies on the fact that \(\alpha\) and \(\Delta \alpha\) are deterministic. Now assume \(\alpha^* \in A_0\) is an optimal argument, then \(\Delta J \leq 0\) for all possible \(\Delta \alpha\). Assume further that \(\alpha^*\) is an inner point of \(\mathcal{A}\) in the sense that one may choose \(\Delta \alpha\) in all directions. Then

\[
\mathbb{E}[\tilde{Y}^{\alpha^*}_t] \partial_b(t, \alpha^*_t) + \partial_a f(t, \alpha^*_t) = 0.
\]

Assume \(b\) and \(f\) are such that the above equation determines a function \(\tilde{I}(t, x)\) such that \(\alpha^*_t = \tilde{I}(t, \mathbb{E}[\tilde{Y}^{\alpha^*}_t])\). Then, denoting \(X^* := X^{\alpha^*}, \tilde{Y}^* := \tilde{Y}^{\alpha^*}, \tilde{Z}^* := \tilde{Z}^{\alpha^*}\), we obtain the following coupled forward backward SDE:

\[
X^*_t = x + \int_0^t b(s, \tilde{I}(s, \mathbb{E}[\tilde{Y}^{\alpha^*}_s])) ds + W_t, \quad \tilde{Y}^*_t = \partial_x g(X^*_T) - \int_t^T \tilde{Z}^*_s dW_s.
\]

We emphasize that the above FBSDE is of McKean-Vlasov type because the forward one includes \(\mathbb{E}[\tilde{Y}^{\alpha^*}_t]\), which is determined by the law of \(X^*\) rather than the value of \(Y^*\). Assume the above FBSDE is well-posed and we have the decoupling field: \(\tilde{Y}^*_t = \tilde{V}(t, \mathcal{L}^t_{\xi^*}, X^*_t)\), which without surprise involves the law of \(X^*\). Denote \(I(t, \mu) := \tilde{I}(t, \mathbb{E}[\tilde{V}(t, \mu, \xi)])\), where as usual \(\mathcal{L}^t_{\xi^*} = \mu\). Then \(\tilde{I}(t, \mathbb{E}[\tilde{Y}^{\alpha^*}_t]) = I(t, \mathcal{L}^t_{\xi^*})\), and thus

\[
X^*_t = x + \int_0^t b(s, \tilde{I}(s, \mathcal{L}^t_{\xi^*})) ds + W_t,
\]

which is consistent with (2.18).

**Remark A.1** When the control \(\alpha_t\) is \(\mathcal{F}_t\)-measurable, the first equality of (A.2) still holds but the second fails. Due to the arbitrariness of \(\Delta \alpha\), in this case the first order condition (A.3) becomes:

\[
\tilde{Y}^{\alpha^*}_t \partial_b(t, \alpha^*_t) + \partial_a f(t, \alpha^*_t) = 0.
\]

This leads to \(\alpha^*_t = \tilde{I}(t, \tilde{Y}^{\alpha^*}_t)\) which in turn leads to a standard FBSDE. These are very standard arguments in the literature. Again, here due to our constraint of deterministic control, the optimal control \(\alpha^*_t\) depends on \(\mathbb{E}[\tilde{Y}^{\alpha^*}_t]\) instead of \(\tilde{Y}^{\alpha^*}_t\), and hence depends on the law of \(X^*_t\).

**B**

In this appendix, we will show some mathematical details of the discussion outlined in Section 1.1. Specifically, we will describe some aspects of the noisy observation case and how it compares to ours. The state variable \(X\) is governed by the dynamics (2.1). For simplicity of notation, we assume \(d = 1\) and \(\sigma \equiv 1\) in what follows. Then,

\[
X^{t, \xi, \alpha}_s = \xi + \int_t^s b(r, X^{t, \xi, \alpha}_r, \alpha_r) dr + W_s - W_t, \ s \in [t, T],
\]

\[
J(t, p, \alpha) := \mathbb{E}^p \left[ g(X^{T, \xi, \alpha}_T) + \int_t^T f(s, X^{t, \xi, \alpha}_s, \alpha_s) ds \right].
\]
for $\xi$ with probability density $p$. Differently from the previous control problem, the agent observes a non-linear noisy process given by

$$Y_s = \int_t^h r(X_{r,s}^{t,a})dr + \tilde{W}_s,$$

where $\tilde{W}$ is a Brownian motion independent of $W$. Thus, an admissible control $\alpha$ has to be progressively measurable with respect to the filtration generated by $Y$. $\{F_s^Y\}_{t \leq a}$ We will denote this space by $\tilde{\mathcal{A}}_{[0,T]}$. Hence, the value function is given by

$$V(t, p) := \sup_{\alpha \in \tilde{\mathcal{A}}_{[t,T]}} J(t, p, \alpha).$$  \hfill (B.2)

We will follow closely the approach of Beneš and Karatzas [1983]. First we introduce some notations. Given two functions $\varphi, \psi : \mathbb{R}^d \rightarrow \mathbb{R}$, denote $\langle \varphi, \psi \rangle := \int_{\mathbb{R}^d} \varphi(z)\psi(z)dz$. Given a function $F : \mathcal{L}^2(\mathcal{F}) \rightarrow \mathbb{R}$, its derivative with respect to $p$ is a function $\partial_p F(p) : \mathcal{L}^2(\mathcal{F}) \rightarrow \mathbb{R}$, defined in the Gâteaux sense:

$$\frac{d}{d\varepsilon} F(p + \varepsilon \varphi) \bigg|_{\varepsilon = 0} = \langle \partial_p F(p), \varphi \rangle,$$

for appropriate test function $\varphi : \mathbb{R}^d \rightarrow \mathbb{R}$. The second order derivative $\partial_{pp} F(p)$ is defined similarly through $\langle \partial_{pp} F, [\varphi, \psi] \rangle$ and can be viewed as a bilinear mapping. Moreover, $\partial_p$ and $\partial_p$ are related through the equation (see e.g. Bensoussan et al. [2017]): for measure $\mu$ with density $p$,

$$\partial_p F(\mu, x) = \partial_x \partial_p F(p)(x).$$  \hfill (B.3)

Beneš and Karatzas [1983] show that dynamics of a proper unnormalized density of the distribution of $X_t^a$ given $F_s^Y$, denoted by $\rho_s$, is given by

$$d\rho_s^{t,p}(x) = \mathcal{L}_s^{\mu,a} \rho_s^{t,p}(x)dt + h(s, x)\rho_s^{t,p}(x)dY_s,$$

with $\rho_t^{t,p} = p$, which is the unnormalized density of $X_t$, and

$$\mathcal{L}_s^{\mu,a} = \frac{1}{2} \partial_{xx} - b(s,x,a)\partial_x - \partial_p b(s,x,a).$$

Moreover, one may write

$$J(t, p, \alpha) = \mathbb{E} \left[ \langle g, \rho_T^{t,p} \rangle \right] + \int_t^T \langle f(s, \cdot, a), \rho_s^{t,p} \rangle \, ds.$$  

Under certain condition, $V$ satisfies the following HJB equation (see [Beneš and Karatzas, 1983, Equations (2.14)-(2.15)]) with terminal condition $V(T, p) = \langle g, p \rangle$:

$$\partial_t V(t, p) + \frac{1}{2} \left\langle \partial_{pp} V(t, p), [h(t, \cdot)p, h(t, \cdot)p] \right\rangle + \sup_{\alpha \in A} \left( \partial_p V(t, p, \mathcal{L}_t^{\mu,a} p) + \langle f(t, \cdot, a), p \rangle \right) = 0.$$  \hfill (B.4)

We would like to point out that the deterministic control problem studied in Section 2 is equivalent to the noisy observation control problem with $h \equiv 0$, i.e. the pure noise case. Under this situation, we will now show that the master equation (2.12) is the HJB equation (B.4), when restricted to those measures with density. In fact, in this case, the HJB equation (B.4) becomes

$$\partial_t V(t, p) + \sup_{\alpha \in A} \left( \partial_p V(t, p, \mathcal{L}_t^{\mu,a} p) + \langle f(t, \cdot, a), p \rangle \right) = 0.$$  \hfill (B.5)
By using integrating by parts formula, we have
\[
\langle \partial_p V(t, p), \partial_{xx} p \rangle = \langle \partial_{xx} \partial_p V(t, p), p \rangle;
\]
\[
\langle \partial_p V(t, p), b(t, \cdot, a) \partial_x p \rangle = -\langle \partial_x \partial_p V(t, p) b(t, \cdot, a) + \partial_p V(t, p) \partial_x b(t, \cdot, a), p \rangle.
\]
Then, for measure $\mu$ with density and by using (B.3),
\[
\langle \partial_p V(t, p), L^\mu_i p \rangle = \left\langle \partial_p V(t, p), \frac{1}{2} \partial_{xx} p - b(t, \cdot, a) \partial_x p - \partial_x b(t, \cdot, a) p \right\rangle
\]
\[
= \left\langle \frac{1}{2} \partial_{xx} \partial_p V(t, p) + b(t, \cdot, a) \partial_x \partial_p V(t, p), p \right\rangle
\]
\[
= \left\langle \frac{1}{2} \partial_x \partial_p V(t, \mu) + b(t, \cdot, a) \partial_\mu V(t, \mu), p \right\rangle.
\]
Plug this into (B.4) we obtain our master equation (2.12) immediately.
