ABSTRACT

Coronavirus disease 2019 (COVID-19) is a fatal and evolving disease and associated with more complication such as respiratory failure and requirement of mechanical ventilation in intensive care unit (ICU). Tracheostomy is a commonly performed surgical procedure done at ICU for prolonged ventilation of the COVID-19 patients. The indications and timing to do tracheostomy on COVID-19 patients are controversial. The requirement of prolonged invasive mechanical ventilation in COVID-19 patients is placing to increased request to perform tracheostomy. The role of performing tracheostomy in COVID-19 patients is exactly not known. Currently, there is no clear-cut evidence for improvement of the clinical course of COVID-19 patients. However, it is confirmed that tracheostomy decreases the ICU stay. Tracheostomy is usually suggested for avoiding potential tracheal injury within 7 to 14 days. Currently, there is uncertainty for timing of tracheostomy, prognosis of the patients and safety of health care professionals. Enhanced personal protective equipment and optimized tracheostomy can make the procedure safe and beneficial in COVID-19 patients. The need of tracheostomy is increasing in current COVID-19 pandemic. We have to perform this surgical procedure in proper time with safe manner for benefit of the patients and health care professionals. This review article focuses on the indications and optimum timing for performing tracheostomy on COVID-19 patients in ICU.

Keywords: COVID-19, SARS-CoV-2, Timing of tracheostomy, Indications of tracheostomy, ICU

INTRODUCTION

COVID-19 is a fatal and highly infectious disease caused by severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) virus. The clinical manifestations of COVID-19 patients may vary from throat pain, fever and myalgia to severe respiratory problem like acute respiratory distress syndrome (ARDS) and even respiratory failure. Severe COVID-19 patients may require endotracheal intubation and mechanical ventilation to help their potential recovery and in about 4 to 5% of such patients, invasive mechanical ventilation is needed. To avoid complications of prolonged intubation, tracheostomy can be considered by health care professionals. Tracheostomy is one of the important surgical procedures done among the critical ill patients for prolonged ventilation. Tracheostomy is an aerosol producing surgery with high chance of transmission of infection for health care professionals. It has important implications in patient care and spread of infections. There are several guidelines and recommendations for performing tracheostomy in COVID-19 patients but the indications and exact timing for tracheostomy is variable and unclear. The timing of tracheostomy in COVID-19 patients indicates the outcome of the patient care in ICU. Tracheostomy usually reduces the ICU stay in context to prolonged invasive mechanical ventilation where they suggested within 7 to 14 days avoiding complications like damage to the trachea. Performing tracheostomy in...
COVID-19 patients reduce duration of mechanical ventilation but its utility for recovery of COVID-19 patients is still not known.6 As tracheostomy is an aerosol-generating procedure, it increases health care professional’s exposure to COVID-19 infection, but the time of the viral load and transmission rate of this infection are not yet exactly known. The indications and exact timing of tracheostomy in COVID-19 patients are often pose challenges in front of surgeon and health care professionals which are associated with safety of patients and health care professionals.

There are not many studies for defining the indications and optimum time to perform tracheostomy on COVID-19 patients at ICU. Here, the aim of this review article is to discuss the indications and optimum timing for performing tracheostomy on the COVID-19 patients at the intensive care unit.

METHODS OF LITERATURE SEARCH

We performed a literature review for indications and optimum timing for performing tracheostomy in COVID-19 patients during the current pandemic consisting data base of PubMed, Medline, SCOPUS and Google scholar search with the words COVID-19, SARS-CoV-2 and indications of tracheostomy and timing of tracheostomy. We reviewed the different current articles and recommendations from national and international medical societies and decisions from several government medical councils. This manuscript reviews the details of indications and optimum timing for performing tracheostomy along with epidemiology, preventive measures for transmission of infection. This manuscript presents a baseline from where further prospective trials for indications and optimum timing of tracheostomy could be designed and helpful as a spur for further research in the COVID-19 pandemic and so prevent transmission of infections to medical professions and other patients during this procedure.

EPIDEMIOLOGY

COVID-19 is a highly contagious disease of the respiratory system which occur by novel coronavirus SARS-CoV-2.7 SARS-CoV-2 is β-coronavirus, which is enveloped non-segmented positive sense RNA virus (subgenus sarbecovirus and orthocoronavirinae subfamily).8 This infection is a newly evolving public health crisis threatening the world. The first patient of COVID-19 infection was reported in Wuhan, China in late December 2019 by SARS-CoV-2 (severe acute respiratory syndrome corona virus 2) and now rapidly spreading worldwide.9 World health organization (WHO) declared the COVID-19 infection as pandemic on March 11, 2020.9 In the hospital setting, critically ill patients with respiratory failure often need endotracheal intubation and changed to tracheostomy in case of prolonged ventilation.9 The incubation of the COVID-19 infection is 1-14 days, mostly 3-7 days and the COVID-19 is contagious during the latency period.10 One study shows 4 to 5% of such severe COVID-19 patients need invasive mechanical ventilation.10 In one study, 6.30% patients need tracheostomy during the COVID-19 outbreak.11 Study showing 7.3-32% COVID-19 patients lead to revere respiratory failure or critical ill condition, where patient may subsequently need tracheostomy for different reasons.12,13 Patients with COVID-19 infections are likely to undergo tracheal intubation and mechanical ventilation support. Data from Europe showed that most critically ill patients, the duration of invasive ventilation can be up to 21 days.14 Guidelines for performing a tracheostomy are made to minimize duration of mechanical ventilation and duration of stay at ICU but its benefits towards recovery of patient from COVID-19 infection is not known.15

TRACHEOSTOMY AND RISK OF INFECTIONS

There are some procedures in COVID-19 patients, capable to generate aerosols such as non-invasive ventilation, tracheal intubation, tracheostomy and manual ventilation before intubating the patients.16 These aerosol generating procedures are usually associated with high chance of SARS transmission.16 SARS-CoV-2 is usually spread via droplet infection and contact, so careful attention must be made during airway.17 In patients with COVID-19 infection, prolonged intubation and mechanical ventilation often require tracheostomy. However, many clinicians avoid it because of the risk of transmission of infection during the procedure and also during the process of the care for patients afterwards. There is a universal agreement that performing tracheostomy on COVID-19 patient’s result in increased chance of viral transmission to health care professionals and other patients nearby. So, tracheostomy is considered as one of the most high-risk surgical procedures in COVID-19 patients. To avoid transmission of infections to tracheostomy team and surrounding health care professionals, adequate preparations is required (Table 1). Percutaneous dilatational tracheostomy is a minimally invasive procedure and less chance of transmitting infections to health care professionals than open tracheostomy.18 However, in certain situations like unfavourable neck anatomy, thyroid gland enlargement and cicatricial contracture of neck are not suitable for percutaneous tracheostomy. In these situations, open tracheostomy is an inevitable choice and this open tracheostomy is more vulnerable to result secretion spatter and contribute nosocomial spread of viruses from patients to personnel in the operating room. At the time of tracheostomy procedure in a COVID-19 patient, meticulous care should be paid to the surgical and anaesthetic technique to reduce the cross-contamination and occupational infection among health care professionals.19 Tracheostomy provides several advantages to the patients such as improved comfort, decreased sedative, paralytic medical support and decreased dead space. Moreover, the tracheostomy also decreases airway resistance and decreasing the work of bearing optimizing the tracheal secretion control.20
Table 1: Preparation for performing tracheostomy on COVID-19 patients.

| Operating site                        | Operating team                     | Operating time               | During opening the trachea                  | Nursing care                      |
|---------------------------------------|------------------------------------|------------------------------|--------------------------------------------|-----------------------------------|
| Isolation area with negative pressure | Full PPE, head cap face shield Goggles | Over 14 days after tracheal intubation | Paralyze the patient                        | Safe suction of the secretions    |
| Limited number of persons involved    | Double gloves                      | When failure to spontaneous breathing trial (SBT) | Push the endotracheal tube cuff caudally for avoiding air leakage | Regular checking of cuff pressure |
| Surgical equipment should be ready    | Mask-N95, FFP3 or FFP2             | Difficult intubation         | Hyper inflate the cuff of the tube          | Stoma care                        |
| Operating time                        | Gowns (Double gown preferable)     | Re-intubation                | Avoid electrocautery. Smoke evacuated if electrocautery used | Staff should be trained for the airway management |

INDICATIONS OF TRACHEOSTOMY

Tracheostomy is a commonly performed surgical procedure in intensive care unit and helpful for weaning from ventilator support, enhance pulmonary toilet, increase patient comfort and routinely performed living activity, decrease laryngeal injury by endotracheal intubation and prevent long-term complications like subglottic or tracheal stenosis. However, the surgical indications of the tracheostomy are greatly affected by the general health condition of the patient, comorbidity, prognosis, staff experience and hospital resources. Tracheostomy is an important surgical procedure in current coronavirus disease 2019 (COVID-19) pandemic particularly those cases undergoing prolonged tracheal intubation. In current COVID-19 pandemic, the tracheostomy is usually performed in reverse transcription polymerase chain reaction (RT PCR) tested COVID-19 patient with prolonged mechanical ventilation. The progressive increase of the COVID-19 patients will expect more requirements of the orotracheal intubation and prolonged ventilation. In this clinical context of ICU, tracheostomy can be considered by health care professionals. Performing tracheostomy on COVID-19 patients or suspected patients for COVID-19 infection imposes challenges not only to otolaryngologists but also to the entire health care team. If the tracheostomy is not an emergency, this can be reviewed by a multidisciplinary team and risk versus benefits of this surgery and also the associated health care team should be assessed. Unlike the bacterial pneumonia, COVID-19 patients present with dry cough and produce little mucus and secretions, so it makes tracheostomy for pulmonary toilet less critical. Study showed, patients with COVID-19 infections and respiratory failure require ventilator support more than 4 weeks, which result in prolonged rehabilitation as well as severe critical illness and neuropathy. Performing tracheostomy on COVID-19 patients in ICU impose challenges on health care professionals including operating surgeon. Before performing surgical tracheostomy, this can be properly assessed for indications with effective outcome and benefit for the patients. Tracheostomy is an effective and safe surgical procedure performed for patients with prolonged endotracheal intubation as in acute respiratory failure. The decision for performing tracheostomy in COVID-19 patients is often based on standard weaning procedure. However, the decision for performing tracheostomy should consider for both benefits of the patient and occupational infection of SARS-CoV-2 in health care professionals during the COVID-19 pandemic. In current COVID-19 pandemic, clinicians must carefully consider the indications of tracheostomy on patients with COVID-19 in the ICU.

TIMING OF TRACHEOSTOMY

The optimal timing to perform tracheostomy in COVID-19 patients remains controversial and highly dependent on the hospital, region and country. Timing of tracheostomy is an important relation with safety of the patients and health care professionals. The recommendations for performing tracheostomy from international, multidisciplinary experts suggested that it should be done at least 10 days after endotracheal intubation in COVID-19 patients. Current data from Europe suggested that most of critically ill patients, the duration of invasive ventilation could go up to 21 days. In current COVID-19 pandemic, the critical cases have been defined by presence of respiratory failure requiring mechanical ventilation and treatment at ICU. One study suggested deferring tracheostomy after 21 days of intubation and suggested open surgical tracheostomy over percutaneous dilatational tracheostomy. Similarly New York head and neck society suggested a 14-day standard with mean (SD) of 10.6 days. Guidelines regarding exact timing of tracheostomy consider scarcity of ventilators and other resources in ICU. One study suggested no sooner than two to three weeks after endotracheal intubation, despite the fact that the long-term laryngotracheal complications may be seen in prolonged intubation.

PREVENTION OF INFECTIONS DURING TRACHEOSTOMY

Severely COVID-19 patients have high chance for requirement of prolonged intubation, making tracheostomy a likely consideration. The contagious nature of COVID-19 infection results an additional risk of
viral transmission to health care professionals which should be taken into consideration. Tracheostomy is an aerosol generating procedures and it increases the exposure of health care workers to COVID-19 infections. Performing the tracheostomy and post-tracheostomy care need a strategy which mitigates these risks and enhances the quality of patient care. The establishment of a surgical tracheostomy strategy, experienced surgical team and use of appropriate personal protective equipment (Figure 1) in each hospital is needed to prevent transmission of infection.\(^\text{35}\)

![Figure 1: Surgeon with personal protective equipment (PPE) before performing tracheostomy.](image)

To enhance the safety of tracheostomy in COVID-19 patients, a reusable type of instrument which consists of a transparent plastic shield with a sloping angled surface and a plastic drop attached to the top and side edges of the face shield.\(^\text{36}\) Personal protective equipment (PPE) is considered as the primary means to decrease the transmission of SARS-CoV-2 virus to health care personnel.\(^\text{37}\) The surgical team should wear enhanced PPE including N-95 mask or FFP3, surgical cap, goggles and face shield, surgical gown (preferable double gown) and gloves (use of double nitrile gloves). Head cap and shoe covers are considered necessary safety of the health care workers. Tracheostomies should be performed in the ICU with negative pressure rooms for avoiding unnecessary transport of patients and repeated connections and disconnection of ventilator circuits during the transfer of patients.\(^\text{38}\) Senior or experiences staffs should perform the tracheostomy on COVID-19 patients. The number of health care professionals in this procedure should be kept to minimum number. Tracheostomy can be done as an open or percutaneous procedure, depending on the surgeon preference and patient factors. Two surgeons, one intensivist, one staff nurse of intensive care and two scrub nurses are ideally required to perform the tracheostomy. One scrub nurse should not enter the room but support the personnel in donning and doffing of the PPE and for preparation of surgical instruments. During tracheostomy, provide adequate sedation such paralysis which eliminates the risk of coughing during the procedure.\(^\text{39}\) Ventilation should be paused (apnoea) at the end-expiration when making opening on the trachea where the ventilation circuit is disconnected. A non-fenestrated cuffed tracheostomy tube is better and it keeps the cuff inflated to stop the spread of the virus through the upper airway. Tracheostomy suctioning is should be done by a closed suction system with a viral filter. Heat moisture exchanger device can be used instead of tracheostomy collar at the time of the weaning for preventing virus spread or re-infection of the patient. The tracheostomy tube changing time of the weaning is extended with ventilator. The tracheostomy tube changing procedure and associated high droplet and particle generating which pose risk for transmission of COVID-19 infection to health care providers. So, indications and timing of tracheostomy on COVID-19 patients is always challenging. There are still controversial for exact indications and timing for tracheostomy in COVID-19 patients. It is thus crucial for ICU teams and surgical personnel and they should be well prepared for performing the tracheostomy when required. Proper indications and optimum timing for performing tracheostomy are important decisions for health care professionals before the procedure. An experienced team of health care professionals is required for performing a safe tracheostomy in COVID-19 patients and to reduce the risk of occupational SARS-CoV-2 infection to them and others.

**CONCLUSION**

Presently COVID-19 is a challenge for global health care professionals. As the COVID-19 infection escalates, the staying of the patient in ICU is extended with ventilator. Acute respiratory distress syndrome and respiratory failure are serious complications of COVID-19 infection which need mechanical ventilation. Tracheostomy is needed in case of prolonged ventilation. Tracheostomy is an aerosol-producing procedure and associated high droplet and particle generating which pose risk for transmission of COVID-19 infection to health care providers. So, indications and timing of tracheostomy on COVID-19 patients is always challenging. There are still controversial for exact indications and timing for tracheostomy in COVID-19 patients. It is thus crucial for ICU teams and surgical personnel and they should be well prepared for performing the tracheostomy when required. Proper indications and optimum timing for performing tracheostomy are important decisions for health care professionals before the procedure. An experienced team of health care professionals is required for performing a safe tracheostomy in COVID-19 patients and to reduce the risk of occupational SARS-CoV-2 infection to them and others.
