Abstract. In this paper we consider a class of nonlinear periodic differential systems perturbed by two nonlinear periodic terms with multiplicative different powers of a small parameter \( \varepsilon > 0 \). For such a class of systems we provide conditions which guarantee the existence of periodic solutions of given period \( T > 0 \). These conditions are expressed in terms of the behaviour on the boundary of an open bounded set \( U \) of \( \mathbb{R}^n \) of the solutions of suitably defined linearized systems. The approach is based on the classical theory of the topological degree for compact vector fields. An application to the existence of periodic solutions to the van der Pol equation is also presented.

Keywords: periodic solutions, nonlinear small perturbations, topological degree, van der Pol equation.

1 Introduction

This paper represents the continuation of the work started by the authors in [8]. There we considered the existence problem both of periodic solutions and of solutions of the Cauchy problem for a system of ordinary differential equations described by

$$\dot{x} = \psi(t, x) + \varepsilon \phi(t, x),$$  \hspace{1cm} (1)

where $\phi, \psi : \mathbb{R} \times \mathbb{R}^n \rightarrow \mathbb{R}^n$ are continuously differentiable, $T$-periodic with respect to time $t$, functions and $\varepsilon$ is a small positive parameter.

To solve this problem for $\varepsilon > 0$ sufficiently small a new approach was presented in [8]. Such an approach is based on the linearized system

$$\dot{y} = \frac{\partial \psi}{\partial x}(t, \Omega(t, 0, \xi)) y + \phi(t, \Omega(t, 0, \xi)), \hspace{1cm} (2)$$

where $\xi \in \mathbb{R}^n$ and $\Omega(\cdot, t_0, \xi)$ denotes the solution of (1) at $\varepsilon = 0$ satisfying $x(t_0) = \xi$. Specifically, consider the change of variable

$$z(t) = \Omega(0, t, x(t)), \hspace{1cm} (3)$$

and the solution $\eta(\cdot, s, \xi)$ of (2) such that $y(s) = 0$. If there exists a bounded open set $U \subset \mathbb{R}^n$ such that $\Omega(T, 0, \xi) = \xi$ for any $\xi \in \partial U$, and $\eta(T, s, \xi) - \eta(0, s, \xi) \neq 0$, for any $s \in [0, T]$, and any $\xi \in \partial U$. Then (1) has a $T$-periodic solution for $\varepsilon > 0$ sufficiently small provided that $\gamma(\eta(T, 0, \cdot)) \neq 0$. Here $\gamma(F, U)$ denotes the rotation number of a continuous map $F : \overline{U} \rightarrow \overline{U}$.

The advantage of the proposed approach as compared with the classical averaging method, which is one of the most useful tool for treating this problem, mainly consists in the fact that in order to use this second method for establishing the existence of periodic solutions in perturbed systems of the form (1) one must assume that the change of variable (3) is $T$-periodic with respect to $t$ for every $T$-periodic function $x$ such that $\Omega(0, t, x(t)) \in U, t \in [0, T]$, instead that only on the boundary of the bounded open set $U$.

The same assumption is necessary in vibrational control problems, [12] and [2], to reduce the considered system to the standard form for applying the averaging method. For an extensive list of references on this topic see [5].

Our approach has been also employed in [9] to prove the existence of periodic solutions for a class of first order singularly perturbed differential systems.

The aim of this paper is to extend the previously outlined approach to a more general class of perturbed systems than (1). Precisely, we consider here systems of the following form:

$$\dot{x} = \psi(t, x) + \varepsilon^2 \phi_1(t, x) + \varepsilon^3 \phi_2(t, x, \varepsilon),$$  \hspace{1cm} (4)

where the functions $\psi, \phi_1 : \mathbb{R} \times \mathbb{R}^n \rightarrow \mathbb{R}^n$, $\phi_2 : \mathbb{R} \times \mathbb{R}^n \times [0, 1] \rightarrow \mathbb{R}^n$ are continuously differentiable! and $T$-periodic with respect to the first variable
and $\varepsilon$ is a small positive parameter. We denote again by $\Omega(\cdot, t_0, \xi)$ the solution of the Cauchy problem

$$\begin{cases}
\dot{x} = \psi(t, x), \\
x(t_0) = \xi,
\end{cases} \quad (5)$$

and by $\eta_i(\cdot, s, \xi), i = 1, 2$, the solution of the Cauchy problems

$$\begin{cases}
\dot{y} = \frac{\partial \psi}{\partial x}(t, \Omega(t, 0, \xi))y + \phi_1(t, \Omega(t, 0, \xi)), & \text{if } i = 1, \\
\dot{y} = \frac{\partial \psi}{\partial x}(t, \Omega(t, 0, \xi))y + \phi_2(t, \Omega(t, 0, \xi), 0), & \text{if } i = 2, \\
y(s) = 0.
\end{cases} \quad (6)$$

In Section 2 we prove the main result of the paper: Theorem 1. Indeed, under suitable assumptions on $\Omega(T, 0, \xi)$ and $\eta_i(T, s, \xi), i = 1, 2$, for $s \in [0, T]$ and $\xi \in \partial U$, for $\varepsilon > 0$ sufficiently small, we prove the existence of $T$-periodic solutions of system (4) provided that $\deg(\eta_2(T, 0, \cdot), U) \neq 0$. Moreover, as it is shown in Theorem 2, in the case of system (1) this result implies Theorem 1 of [8]!

In Section 3, we apply Theorem 1 to autonomous systems in $\mathbb{R}^2$ perturbed by a non-autonomous term of higher order (with respect to $\varepsilon > 0$) to show the existence of periodic solutions in a suitable open set defined by means of the trajectory of the linear part of the autonomous system.

Finally, in Section 4 we illustrate the obtained results by means of an example concerning the van der Pol equation. To the best knowledge of the authors this represents a new approach to investigate the existence of periodic solutions for the periodically forced van der Pol equation. Indeed, many papers in the literature are devoted to the study of the response of the van der Pol equation to periodic stimulus (of different period), but the methods are quite different, in fact they are essentially based on asymptotic expansions, Fourier series, singular perturbation theory and averaging methods. We refer to the papers [3], [4], [6], [7] and the references therein.

2 Main results

Consider the system

$$\dot{x} = \psi(t, x) + \varepsilon^2 \phi_1(t, x) + \varepsilon^3 \phi_2(t, x, \varepsilon), \quad (7)$$

where the functions $\psi, \phi_1 : \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}^n$, $\phi_2 : \mathbb{R} \times \mathbb{R}^n \times [0, 1] \to \mathbb{R}^n$ are continuously differentiable, $T$-periodic with respect to time $t$, and $\varepsilon$ is a small positive parameter.
To investigate the existence of $T$-periodic solutions of system (7) we introduce the compact integral operator $F_\varepsilon : C([0,T], \mathbb{R}^n) \to C([0,T], \mathbb{R}^n)$ defined by

$$F_\varepsilon(x)(t) = x(t) - x(T) - \int_0^t \left( \psi(\tau, x(\tau)) + \varepsilon^2 \phi_1(\tau, x(\tau)) + \varepsilon^3 \phi_2(\tau, x(\tau), \varepsilon) \right) d\tau,$$

for any $t \in [0,T]$. Clearly if $F_\varepsilon(x) = 0$ then $x$ is a $T$-periodic solution of system (7).

Denote by $\Omega(\cdot, t_0, \xi)$ the solution of the Cauchy problem

$$\begin{cases}
\dot{x} = \psi(t, x), \\
x(t_0) = \xi,
\end{cases} \quad (8)$$

and by $\eta_i(\cdot, s, \xi), 1 = 1, 2$, the solution of the Cauchy problems

$$\begin{cases}
\dot{y} = \frac{\partial \psi}{\partial x}(t, \Omega(t, 0, \xi))y + \phi_1(t, \Omega(t, 0, \xi)), & \text{if } i = 1, \\
\dot{y} = \frac{\partial \psi}{\partial x}(t, \Omega(t, 0, \xi))y + \phi_2(t, \Omega(t, 0, \xi), 0), & \text{if } i = 2, \\
y(s) = 0.
\end{cases} \quad (9)$$

The following lemma provides an explicit representation of the functions $\eta_1$ and $\eta_2$.

**Lemma 1.** Let $\xi \in \mathbb{R}^n$ and $s, t \in [0, T]$. We have that

$$\eta_1(t, s, \xi) = \frac{\partial \Omega}{\partial z}(t, 0, \xi) \int_s^t \Phi_1(\tau, \xi) d\tau$$

where

$$\Phi_1(t, \xi) = \frac{\partial \Omega}{\partial z}(0, t, \Omega(t, 0, \xi))\phi_1(t, \Omega(t, 0, \xi))$$

and

$$\eta_2(t, s, \xi) = \frac{\partial \Omega}{\partial z}(t, 0, \xi) \int_s^t \Phi_2(\tau, \xi, 0) d\tau$$

where

$$\Phi_2(t, \xi, \varepsilon) = \frac{\partial \Omega}{\partial z}(0, t, \Omega(t, 0, \xi))\phi_2(t, \Omega(t, 0, \xi), \varepsilon).$$
Proof.  
It is sufficient to observe, that the matrix \( \frac{\partial \Omega}{\partial z}(t, 0, \xi) \) is the fundamental matrix of the linear system
\[
\dot{y} = \frac{\partial \psi}{\partial x}(t, \Omega(t, 0, \xi))y
\]
Moreover, \( \left( \frac{\partial \Omega}{\partial z}(t, 0, \xi) \right)^{-1} = \frac{\partial \Omega}{\partial z}(0, t, \Omega(t, 0, \xi)) \). In fact, if we derive with respect to \( \xi \) the identity
\[
\Omega(0, t, \Omega(t, 0, \xi)) = \xi
\]
we obtain
\[
\frac{\partial \Omega}{\partial z}(0, t, \Omega(t, 0, \xi)) \frac{\partial \Omega}{\partial z}(t, 0, \xi) = I,
\]
whenever \( \xi \in \mathbb{R}^n \). Therefore, by the variation of constants formula for linear nonhomogeneous system
\[
\dot{y} = \frac{\partial \psi}{\partial x}(t, \Omega(t, 0, \xi))y + \phi_1(t, \Omega(t, 0, \xi)),
\]
we have
\[
\eta_1(t, s, \xi) = \int_s^t \frac{\partial \Omega}{\partial z}(t, 0, \xi) \left( \frac{\partial \Omega}{\partial z}(\tau, 0, \xi) \right)^{-1} \phi_1(\tau, \Omega(\tau, 0, \xi))d\tau = \frac{\partial \Omega}{\partial z}(t, 0, \xi) \int_s^t \Phi_1(\tau, \xi)d\tau.
\]
The formula for \( \eta_2 \) is obtained in the same way. \( \square \)

We have the following result.

**Theorem 1.** Let \( U \subset \mathbb{R}^n \) be an open and bounded set. Assume, that

(A1) \( \Omega(T, 0, \xi) = \xi \), !for any! \( \xi \in \partial U \),

(A2) \( \eta_1(T, s, \xi) - \eta_1(0, s, \xi) = 0 \), !for any! \( s \in [0, T] \) !and any! \( \xi \in \partial U \),

(A3) \( \eta_2(T, s, \xi) - \eta_2(0, s, \xi) \neq 0 \), !for any! \( s \in [0, T] \) !and any! \( \xi \in \partial U \).

Then for \( \varepsilon > 0 \) sufficiently small
\[
\deg(F_\varepsilon, W(T, U)) = \deg(\eta_2(T, 0, \cdot), U), \quad (10)
\]
where \( W(T, U) = \{ x \in C([0, T], \mathbb{R}^n) : \Omega(0, t, x(t)) \in U, \text{ whenever } t \in [0, T] \} \).

In order to prove the Theorem we need the following Lemma.

**Lemma 2.** Let \( z \in C^1([0, T], \mathbb{R}^n) \), \( f \in C([0, T], \mathbb{R}^n) \) and \( b \in \mathbb{R}^n \). If
\[ \int_0^t \frac{\partial \Omega}{\partial z}(s, 0, z(s)) \dot{z}(s) ds + z(0) = b + \int_0^t f(s) ds, \quad \text{(11)} \]

then

\[ z(t) = b + \int_0^t \frac{\partial \Omega}{\partial z}(0, s, \Omega(s, 0, z(s))) f(s) ds. \quad \text{(12)} \]

**Proof.**

Take the derivative of (11) with respect to \( t \) and then apply \( \frac{\partial \Omega}{\partial z}(0, \Omega(t, 0, z(t))) \) to both sides. Finally, integrating the resulting differential system from 0 to \( t \) and observing that from (11) we have \( z(0) = b \) one has (12).

**Proof of Theorem 1.**

Let \( x \) be a solution of the equation

\[ F_\varepsilon(x) = 0. \quad \text{(13)} \]

Thus \( x \) is a \( T \)-periodic solution to (7). Consider the change of variable

\[ x(t) = \Omega(t, 0, z(t)), \quad t \in [0, T], \quad \text{(14)} \]

with inverse given by

\[ z(t) = \Omega(0, t, x(t)), \quad t \in [0, T]. \quad \text{(15)} \]

Observe that if \( x \) is a solution of (13) then it is differentiable; in fact, for any \( t \in [0, T] \), we have

\[ x(t) = x(T) + \int_0^t \left( \psi(\tau, x(\tau)) + \varepsilon^2 \phi_1(\tau, x(\tau)) + \varepsilon^3 \phi_2(\tau, x(\tau), \varepsilon) \right) d\tau. \quad \text{(16)} \]

Therefore, from (15) \( z \) is also differentiable. Consider

\[ \frac{d}{dt} \Omega(t, 0, z(t)) = \frac{\partial \Omega}{\partial t}(t, 0, z(t)) + \frac{\partial \Omega}{\partial z}(t, 0, z(t)) \dot{z}(t), \quad \text{(17)} \]

since

\[ \frac{\partial \Omega}{\partial t}(t, 0, z(t)) = \psi(t, \Omega(t, 0, z(t))) \]

from (17) we have that

\[ \Omega(t, 0, z(t)) - z(0) = \int_0^t \psi(s, \Omega(s, 0, z(s))) ds + \int_0^t \frac{\partial \Omega}{\partial z}(s, 0, z(s)) \dot{z}(s) ds, \]

or equivalently,

\[ \Omega(t, 0, z(t)) - \int_0^t \psi(s, \Omega(s, 0, z(s))) ds = z(0) + \int_0^t \frac{\partial \Omega}{\partial z}(s, 0, z(s)) \dot{z}(s) ds. \quad \text{(18)} \]
By using (14), (18) and Lemma 2 with $b = \Omega(T, 0, z(T))$ we can rewrite (16) in the following form

$$G_\varepsilon(z)(t) = 0,$$

(19)

where $G_\varepsilon : C([0, T], R^n) \to C([0, T], R^n)$ is given by

$$G_\varepsilon(z)(t) = z(t) - \Omega(T, 0, z(T)) - \int_0^t (\varepsilon^2 \Phi_1(\tau, z(\tau)) + \varepsilon^3 \Phi_2(\tau, z(\tau), \varepsilon)) d\tau.$$

Therefore the solutions of the equation (13) belonging to the set $W(T, U)$ correspond to the solutions of the equation (19) belonging to the set

$$Z = \{ z \in C([0, T], R^n) : z(t) \in U, \text{ whenever } t \in [0, T] \}.$$

and by the homeomorphism Theorem for compact vector fields (see [10], Theorem 26.4) to prove Theorem 1 it is enough to show that

$$\text{deg}(G_\varepsilon, Z) = \text{deg}(\eta_2(T, 0, \cdot), U)$$

(20)

for $\varepsilon > 0$ sufficiently small.

For this, consider the compact vector field $\tilde{G}_\varepsilon : C([0, T], R^n) \to C([0, T], R^n)$ defined as follows

$$\tilde{G}_\varepsilon = I - A_\varepsilon,$$

where

$$A_\varepsilon(z)(t) = \Omega(T, 0, z(T)) + \int_0^T \left( \varepsilon^2 \Phi_1(\tau, z(\tau)) + \varepsilon^3 \Phi_2(\tau, z(\tau), \varepsilon) \right) d\tau,$$

for any $t \in [0, T]$, hence $A_\varepsilon(z)$ is a constant function in $C([0, T], R^n)$. Let us show that for $\varepsilon > 0$ sufficiently small the compact vector fields $G_\varepsilon$ and $\tilde{G}_\varepsilon$ are homotopic on the boundary of the set $Z$. To this aim, we define, for $\lambda \in [0, 1]$ the following homotopy:

$$\Delta_\varepsilon(\lambda, z)(t) = z(t) - \Omega(T, 0, z(T)) - \int_0^{\lambda t + (1-\lambda)T} \left( \varepsilon^2 \Phi_1(\tau, z(\tau)) + \varepsilon^3 \Phi_2(\tau, z(\tau), \varepsilon) \right) d\tau,$$

whenever $t \in [0, T]$, which deforms the vector field $G_\varepsilon$ to the vector field $\tilde{G}_\varepsilon$.

Let us show that $\Delta_\varepsilon$ does not vanish on the boundary of the set $Z$ for $\varepsilon > 0$ sufficiently small.

Assume the contrary. Therefore there exists a sequence $\{ \varepsilon_k \}_{k=1}^\infty \subset (0, 1]$ such that $\varepsilon_k \to 0$ as $k \to \infty$ and sequences $\{ \lambda_k \}_{k=1}^\infty \subset [0, 1]$ and $\{ z_k \}_{k=1}^\infty \subset \partial Z$ such
that
\[ z_k(t) = \Omega(T, 0, z_k(T)) + \varepsilon_k^2 \int_0^{\lambda_k t + (1-\lambda_k)T} \Phi_1(\tau, z_k(\tau))d\tau + \varepsilon_k^3 \int_0^{\lambda_k t + (1-\lambda_k)T} \Phi_2(\tau, z_k(\tau), \varepsilon_k)d\tau, \quad t \in [0, T]. \]

(21)

Without loss of generality we can assume that \( \lambda_k \to \lambda_0 \) and \( z_k \to z_0 \) in \( C([0, T], \mathbb{R}^n) \) as \( k \to \infty \). Therefore \( \lambda_0 \in [0, 1] \) and \( z_0 \in \partial Z \). Furthermore, there exists a sequence \( \{t_k\}_{k=1}^{\infty} \) such that \( z_k(t_k) \in \partial U \) and by condition (A1)
\[ \Omega(T, 0, z_k(t_k)) = z_k(t_k), \text{ for any } k \in \mathbb{N}. \]

(22)

By subtracting from (21), where \( t \) is replaced by \( T \), the same equation with \( t = t_k \) we obtain
\[ z_k(T) - z_k(t_k) = \varepsilon_k^2 \int_0^{\lambda_k t_k + (1-\lambda_k)T} \Phi_1(\tau, z_k(\tau))d\tau + \varepsilon_k^3 \int_0^{\lambda_k t_k + (1-\lambda_k)T} \Phi_2(\tau, z_k(\tau), \varepsilon_k)d\tau. \]

(23)

By (22) the equation (21) where \( t = T \) can be rewritten as
\[ z_k(T) - z_k(t_k) = \Omega(T, 0, z_k(T)) - \Omega(T, 0, z_k(t_k)) + \varepsilon_k^2 \int_0^T \Phi_1(\tau, z_k(\tau))d\tau + \varepsilon_k^3 \int_0^T \Phi_2(\tau, z_k(\tau), \varepsilon_k)d\tau. \]

or equivalently
\[ \left( I - \frac{\partial \Omega}{\partial z}(T, 0, z_k(t_k)) \right)(z_k(T) - z_k(t_k)) = \]
\[ = \frac{\partial^2 \Omega}{\partial z^2}(T, 0, z_k(t_k))(z_k(T) - z_k(t_k))(z_k(T) - z_k(t_k)) + \varepsilon_k^2 \int_0^T \Phi_1(\tau, z_k(\tau))d\tau + \varepsilon_k^3 \int_0^T \Phi_2(\tau, z_k(\tau), \varepsilon_k)d\tau + o(z_k(t_k), z_k(T) - z_k(t_k)), \]

(24)

where the function \( o(\xi, h) \) satisfy
\[ \frac{\|o(\xi, h)\|}{\|h\|^2} \to 0, \text{ as } \|h\| \to 0, \quad \text{with } h, \xi \in \mathbb{R}^n. \]

(25)
Replacing (23) in (24) and dividing by \( \varepsilon_k^3 > 0 \) after a suitable transformation we obtain

\[
\frac{1}{\varepsilon_k} Q_{1k}(z_k) + Q_{2k}(z_k) = P_k + \frac{1}{\varepsilon_k^3} o(z_k(t_k), z_k(T) - z_k(t_k)) \quad (26)
\]

where

\[
P_k = \varepsilon_k \frac{\partial^2 \Omega}{\partial z^2}(T, 0, z_k(t_k)) \cdot \\
\cdot \left( \lambda_k t + (1 - \lambda_k) T \int_0^T \Phi_1(\tau, z_k(\tau)) d\tau + \varepsilon_k \int_0^T \Phi_2(\tau, z_k(\tau), \varepsilon_k) d\tau \right) \\
\cdot \left( \lambda_k t + (1 - \lambda_k) T \int_0^T \Phi_1(\tau, z_k(\tau)) d\tau + \varepsilon_k \int_0^T \Phi_2(\tau, z_k(\tau), \varepsilon_k) d\tau \right),
\]

and

\[
Q_{1k}(z_k) = \left( I - \frac{\partial \Omega}{\partial z}(T, 0, z_k(t_k)) \right) \int_{\lambda_k t k + (1 - \lambda_k) T}^T \Phi_1(\tau, z_k(\tau)) d\tau \\
- \int_0^T \Phi_1(\tau, z_k(\tau)) d\tau, \\
\]

\[
Q_{2k}(z_k) = \left( I - \frac{\partial \Omega}{\partial z}(T, 0, z_k(t_k)) \right) \int_{\lambda_k t k + (1 - \lambda_k) T}^T \Phi_2(\tau, z_k(\tau), \varepsilon_k) d\tau \\
- \int_0^T \Phi_2(\tau, z_k(\tau), \varepsilon_k) d\tau.
\]

It is easy to see, that

\( P_k \to 0 \) as \( k \to \infty \) \quad (27)

and

\[
\frac{1}{\varepsilon_k^3} o(z_k(t_k), z_k(T) - z_k(t_k)) \to 0 \quad \text{as} \quad k \to \infty.
\]

(28)

Let us show, that

\[
\frac{1}{\varepsilon_k} Q_{1k}(z_k) \to 0 \quad \text{as} \quad k \to \infty.
\]

(29)

We have

\[
\frac{1}{\varepsilon_k} Q_{1k}(z_k) = \frac{Q_{1k}(z_k) - Q_{1k}(c_k) + Q_{1k}(c_k)}{\varepsilon_k} \\
= \frac{\partial Q_{1k}(c_k)}{\partial z} \left( \frac{z_k - c_k}{\varepsilon_k} \right) + \frac{Q_{1k}(c_k)}{\varepsilon_k} + \frac{o_k(z_k - c_k)}{\varepsilon_k},
\]

(30)
where by $c_k$ we denote the constant function $c_k(t) \equiv z_k(t_k)$ for any $t \in [0, T]$ and the function $o_k(\cdot)$ satisfy
\[
\frac{\|o_k(h)\|}{\|h\|} \to 0, \text{ as } \|h\| \to 0, \ h \in C([0, T], \mathbb{R}^n).
\] (31)

By using (23)
\[
\|z_k(t) - c_k\| \leq \varepsilon^2 M,
\] (32)
for any $t \in [0, T]$, where $M \geq 0$ is a constant and so the first and the third term in (30) tends to zero as $k$ tends to $\infty$. Let us prove, that
\[
Q_{1k}(c_k) = 0, \ k \in \mathbb{N}.
\] (33)

By Lemma 1
\[
\left(I - \frac{\partial \Omega}{\partial z}(T, 0, \xi)\right) \int_0^T \Phi_1(\tau, \xi)d\tau - \int_0^T \Phi_1(\tau, \xi)d\tau = \eta_1(0, s, \xi) - \eta_1(T, s, \xi) \tag{34}
\]
and by condition (A2) we obtain (33). Thus (29) holds true and by (27), (28) and (29) we can pass to the limit in (26), obtaining
\[
Q_2(z_0) = 0, \tag{35}
\]
where $Q_2 = \lim_{k \to \infty} Q_{2k}$. On the other hand by Lemma 1 we obtain a result the analogous to (34) for $\Phi_2$, thus
\[
Q_2(z_0) = \eta_2(0, s, z_0(t_0)) - \eta_2(T, s, z_0(t_0)),
\] (36)
where $s = \lim_{k \to \infty}(\lambda_k t_k + (1 - \lambda_k)T)$, hence
\[
\eta_2(0, s, z_0(t_0)) - \eta_2(T, s, z_0(t_0)) = 0,
\] (37)
which contradicts assumption (A3) since $z_0(t_0) \in \partial U$. Therefore, there exists $\varepsilon_0 > 0$ such that
\[
\Delta_\varepsilon(\lambda, z) \neq 0, \ \lambda \in [0, 1], \ z \in \partial Z, \ \varepsilon \in (0, \varepsilon_0)
\] (38)
and so
\[
\deg(G_\varepsilon, Z) = \deg(\tilde{G}_\varepsilon, Z), \ \varepsilon \in (0, \varepsilon_0).
\] (39)

Denote by $C_0([0, T], \mathbb{R}^n)$ the subspace of the space $C([0, T], \mathbb{R}^n)$ consisting of all constant functions defined on $[0, T]$ with values in $\mathbb{R}^n$. We have $A_\varepsilon(\partial Z) \subset C_0([0, T], \mathbb{R}^n)$. From (38) with $\lambda = 0$ we have
\[
\tilde{G}_\varepsilon(z) \neq 0, \ z \in \partial Z, \ \varepsilon \in (0, \varepsilon_0),
\]
and using the inclusion $\partial(Z \cap C_0([0, T], R^n)) \subset \partial Z$ we conclude that the vector field $\tilde{G}_\varepsilon$ does not have zeros on the boundary of the set $Z \cap C_0([0, T], R^n)$ when $\varepsilon \in (0, \varepsilon_0)$. Therefore by the reduction property of the topological degree, (see [10], Theorem 27.1), we have

$$\deg_{C([0, T], R^n)}(\tilde{G}_\varepsilon, Z) = \deg_{C_0([0, T], R^n)}(\tilde{G}_\varepsilon, Z \cap C_0([0, T], R^n)).$$

Furthermore, since the constant function $z \in Z \cap C_0([0, T], R^n)$ is a solution of the equation $\tilde{G}_\varepsilon(z) = 0$ if and only if the element $\xi \in U$, !given by! $\xi = z(t)$, !for any! $t \in [0, T]$, is a solution of the equation $K_\varepsilon \xi = 0$, !where $K_\varepsilon : U \to R^n$ is defined as follows!

$$K_\varepsilon \xi = \xi - \Omega(T, 0, \xi) - \varepsilon^2 \int_0^T \Phi_1(\tau, \xi) d\tau - \varepsilon^3 \int_0^T \Phi_2(\tau, \xi, \varepsilon) d\tau,$$

then

$$\deg_{C_0([0, T], R^n)}(\tilde{G}_\varepsilon, Z \cap C_0([0, T], R^n)) = \deg_{R^n}(K_\varepsilon, U).$$

Consider now $K_{\varepsilon, 2} : U \to R^n$ defined by!

$$K_{\varepsilon, 2} \xi = -\varepsilon^3 \int_0^T \Phi_2(\tau, \xi, \varepsilon) d\tau.$$

By condition (A1), i.e. $\xi - \Omega(T, 0, \xi) = 0$, for any $\xi \in \partial U$, Lemma 1 and assumption (A2) we obtain

$$-\int_0^T \Phi_1(\tau, \xi) d\tau = +\int_0^T \Phi_1(\tau, \xi) d\tau = \eta_1(0, T, \xi) = \eta_1(0, T, \xi) - \eta_1(T, T, \xi) = 0,$$

Therefore $K_\varepsilon \xi = K_{\varepsilon, 2} \xi$, !whenever! $\xi \in \partial U$ and thus

$$\deg_{R^n}(K_\varepsilon, U) = \deg_{R^n}(K_{\varepsilon, 2}, U), \text{ !for any! } \varepsilon \in (0, \varepsilon_0).$$

Finally, consider the vector field $\tilde{K}_{\varepsilon, 2} : U \to R^n$ defined as follows!

$$\tilde{K}_{\varepsilon, 2} \xi = -\int_0^T \Phi_2(\tau, \xi, \varepsilon) d\tau.$$

By condition (A2) we have

$$-\int_0^T \Phi_2(\tau, \xi, 0) d\tau = \eta_2(0, T, \xi) - \eta_2(T, T, \xi) \neq 0,$$

(43)
Therefore there exists $\varepsilon_1 \in (0, \varepsilon_0)$ such that
\[ -\int_0^T \Phi_2(\tau, \xi, \varepsilon) d\tau \neq 0, \text{ for any! } \xi \in \partial U \text{ and any! } \varepsilon \in (0, \varepsilon_1). \]

and so the vector fields $K_{\varepsilon,2}$ and $\tilde{K}_{\varepsilon,2}$ are linearly homotopic on the boundary of the set $U$ for any $\varepsilon \in (0, \varepsilon_1)$. Moreover, by condition (43) the vector fields $\tilde{K}_{\varepsilon,2}$ and $\tilde{K}_{0,2}$ are linearly homotopic on $\partial U$ for $\varepsilon \in (0, \varepsilon_1)$. Therefore
\[
\deg(K_{\varepsilon,2}, U) = \deg(\eta_2(0, T, \xi) - \eta_2(T, T, \xi), U) = \\
= \deg(\eta_2(T, 0, \xi) - \eta_2(0, 0, \xi), U) = \deg(\eta_2(T, 0, \xi), U).
\text{(44)}
\]

Summarizing (39), (40), (41), (42) and (44) we obtain (10), !which is the claim of Theorem 1!.

Consider now the system
\[
\dot{x} = \psi(t, x) + \varepsilon \phi(t, x, \varepsilon), 
\text{(45)}
\]
and
\[
F_\varepsilon(x)(t) = x(t) - x(T) - \int_0^t \left( \psi(\tau, x(\tau)) + \varepsilon \phi(\tau, x(\tau), \varepsilon) \right) d\tau.
\]

Denote by $\eta$ the solution of Cauchy problem (9) associated with (45). As a direct consequence of the previous result we have the following.

**Theorem 2.** Let $U \subset \mathbb{R}^n$ be an open and bounded set. Assume, that
\[
\text{(A1) } \Omega(T, 0, \xi) = \xi, \text{ for any! } \xi \in \partial U, \\
\text{(A2) } \eta(T, s, \xi) - \eta(0, s, \xi) \neq 0, \text{ for any! } s \in [0, T], \text{ and any! } \xi \in \partial U.
\]

Then for $\varepsilon > 0$ sufficiently small
\[
\deg(F_\varepsilon, W(T, U)) = \deg(\eta(T, 0, \cdot), U).
\text{(46)}
\]
Observe that Theorem 1 of [8] follows from Theorem 2 above.

### 3 Small perturbations of autonomous systems

In this Section by using the previous results we provide sufficient conditions to ensure that the topological degree of the integral operator associated to the following system in $\mathbb{R}^2$
\[
\dot{x} = Ax + \varepsilon^2 \phi_1(x) + \varepsilon^3 \phi_2(t, x, \varepsilon), 
\text{(47)}
\]
is different from zero for $\varepsilon > 0$ sufficiently small.
System (47) is regarded here as the perturbed system of the autonomous system
\[ \dot{x} = Ax + \varepsilon^2 \phi_1(x) \] (48)
by means of the $T$-periodic perturbation $\varepsilon^2 \phi_2(t, x, \varepsilon)$, where $A$ is a $2 \times 2$ matrix. At $\varepsilon = 0$ we have the linear system
\[ \dot{x} = Ax. \] (49)

We assume, that

(A1) the matrix $A$ has eigenvalues $i\lambda$ and $-i\lambda$, where $\lambda > 0$.

Let $x_0$ be a non-zero periodic solution of system (49) which is the boundary of an open set $U_0$ of $\mathbb{R}^2$. Observe that such a periodic solution exists in virtue of (A1). Moreover, since the period $T$ of any periodic solution of system (49) is equal to $2\pi/\lambda$, we assume that the function $\phi_2$ is $2\pi/\lambda$-periodic with respect to the first variable.

Denote by $U_\delta$ the open sets whose boundaries are given by the trajectories $(1 + \delta)x_0$ for $\delta \in \mathbb{R}$. Since $x_0$ is a $2\pi/\lambda$-periodic solution of system (49) then $(1 + \delta)x_0$, $\delta \in \mathbb{R}$, is also a $2\pi/\lambda$-periodic solution of this system. Moreover we have $U_0 \subset U_\delta$.

Define $\Omega$, $\eta_1$, $\eta_2$ and $F_\varepsilon$ as in the previous Section with $\psi(t, \xi) = A\xi$ and $T = 2\pi/\lambda$.

We have the following result.

**Theorem 3.** Assume condition (A1). Moreover, assume that for $\delta \in (0, 1)$ we have

(A2) $\eta_1(T, s, \xi) - \eta_1(0, s, \xi) = 0$, !for any! $s \in [0, T]$ and any! $\xi \in \partial U_0$,

(A3) $\eta_2(T, s, \xi) - \eta_2(0, s, \xi) \neq 0$, !for any! $s \in [0, T]$ and any! $\xi \in \partial U_0$,

(A4) $\eta_1(T, s, \xi) - \eta_1(0, s, \xi) \neq 0$, !for any! $s \in [0, T]$ and any! $\xi \in \partial U_\delta$.

Then for all $\varepsilon > 0$ sufficiently small
\[ \deg \left( F_\varepsilon, W(T, U_\delta) \setminus \overline{W(T, U_0)} \right) = \] (50)
\[ = \left( \deg \left( \eta_1(T, 0, \cdot), U_\delta \right) - \deg \left( \eta_2(T, 0, \cdot), U_0 \right) \right). \]

**Proof.**

First of all observe that the set $W(T, U_\delta) \setminus \overline{W(T, U_0)}$ is well defined since $U_\delta \supset U_0$.

Moreover, from (A1), (A2) and (A3) it follows that Theorem 1 is applicable with $U = U_0$ and so for $\varepsilon > 0$ sufficiently small we obtain
\[ \deg(F_\varepsilon, W(T, U_0)) = \deg(\eta_2(T, 0, \cdot), U_0). \] (51)
Finally, (A1) and (A4) imply that Theorem 2 is applicable with $U = U_{\delta}$ and so for $\varepsilon > 0$ sufficiently small we obtain
\[
\deg(F_{\varepsilon}, W(T, U_{\delta})) = \deg (\eta_1 (T, 0, \cdot), U_{\delta}).
\] (52)

Thus (51) and (52) ensure (50) with $\varepsilon > 0$ sufficiently small. \Box

We will show now that if we perturb (48) by a $T_{\varepsilon}$-periodic perturbation, where
\[
T_{\varepsilon} \to T \text{ as } \varepsilon \to 0,
\] (53) then (47) has $T_{\varepsilon}$-periodic solutions. In case all the powers of $\varepsilon$ in the right hand side of (47) are the same and $T_{\varepsilon} \neq T$ this result is called the phenomenon of frequency pulling (see [1]). So we would like to show that in case of the perturbation (47), where the powers of $\varepsilon$ are different, this phenomenon still has a place. As $T_{\varepsilon}$ we consider here $T_{\varepsilon, \mu} = \frac{2\pi}{\lambda(1 + \varepsilon^3 \mu)}$, where $\mu$ is a scaling parameter. More precisely we consider the system!

\[
\dot{x} = Ax + \varepsilon^2 \phi_1 (x) + \varepsilon^3 \phi_2 \left( \frac{t}{1 + \varepsilon^3 \mu}, x, \varepsilon, \mu \right).
\] (54)

Denote by $F_{\varepsilon, \mu}$ the integral operator associated with (54) and denote by $\eta_i (\cdot, s, \xi), \ i = 1, 2$, the solution of (9) corresponding to (54) for $\mu = 0$.

We can formulate the following result.

**Theorem 4.** Assume that for $\mu = 0$ and $!T = \frac{2\pi}{\lambda(1 + \mu)}$ all the conditions of Theorem 3 are satisfied. Then there exists $\mu_0 > 0$ such that for every $\mu \in (-\mu_0, \mu_0)$ there is an $\varepsilon_0 > 0$ such that
\[
\deg \left( F_{\varepsilon, \mu}, W (\!T_{\varepsilon, \mu}, U_{\delta}) \right) \backslash \overline{W (\!T_{\varepsilon, \mu}, U_{0})} =
\]
\[
= \left( \deg (\eta_1 (\!T_{\varepsilon, \mu}, 0, \cdot), U_{\delta}) - \deg (\eta_2 (\!T_{\varepsilon, \mu}, 0, \cdot), U_{\delta}) \right)
\] (55)

for any $\varepsilon \in (0, \varepsilon_0)$.

**Proof.**
In (54) consider the change of variable:
\[
y(t) = x \left( t (1 + \varepsilon^3 \mu) \right).
\] (56)

Thus we obtain the system
\[
\dot{y} = Ay + \varepsilon^2 \phi_1 (y) + \varepsilon^3 \phi_2 (t, y, \varepsilon),
\] (57)

where
\[
\phi_2 (t, \xi, \varepsilon) = \phi_2 (t, \xi, \varepsilon, \mu) + \varepsilon A \xi + \varepsilon^2 \mu \phi_1 (\xi) + \varepsilon^3 \mu \phi_2 (t, \xi, \varepsilon, \mu).
\]
Since the conditions of Theorem 3 hold true for (57) for \( \mu = 0 \) then there exists \( \mu_0 > 0 \) such that the conditions of Theorem 3 hold true for (57) for every fixed \( \mu \in (-\mu_0, \mu_0) \). Observe, that the solution of problem (9) with \( i = 1 \) associated with (54) and that one associated with (57) coincide. Denote by \( \eta_{2,\mu} \) the solution of the problem (9) with \( i = 2 \) associated with (57) and denote by \( G_{\varepsilon,\mu} \) the compact operator corresponding to the \( T_0 \)-periodic problem for the system (57). By Theorem 3 for every \( \mu \in (-\mu_0, \mu_0) \) there exists \( \varepsilon_0 > 0 \) such that

\[
\deg \left( G_{\varepsilon,\mu}, W (T_0, U_\delta) \setminus \overline{W} (T_0, U_0) \right) = \\
= (\deg (\eta_1 (T_0, 0, \cdot), U_\delta) - \deg (\eta_{2,\mu} (T_0, 0, \cdot), U_0))
\]

for \( \varepsilon \in (0, \varepsilon_0) \). Since

\[
\eta_{2,\mu} (T_0, 0, \xi) \to \eta_2 (T_0, 0, \xi) \quad \text{as} \quad \mu \to 0, \quad \text{for any} \quad \xi \in \mathbb{R}^2
\]

we may assume without loss of generality that \( \mu_0 > 0 \) is choosen in such a way that

\[
\deg (\eta_{2,\mu} (T_0, 0, \cdot), U_0) = \deg (\eta_2 (T_0, 0, \cdot), U_0), \quad \text{for any} \quad \mu \in (-\mu_0, \mu_0).
\]

By (56) the zeros of the operator \( G_{\varepsilon,\mu} \) belonging to \( W (T_0, U) \) correspond to the zeros of the operator \( F_{\varepsilon,\mu} \) belonging to \( W (\{T_{\varepsilon,\mu}\}, U) \). Therefore

\[
\deg \left( F_{\varepsilon,\mu}, W (\{T_{\varepsilon,\mu}\}, U_\delta) \setminus \overline{W} (\{T_{\varepsilon,\mu}\}, U_0) \right) = \\
= \deg \left( G_{\varepsilon,\mu}, W (T_0, U_\delta) \setminus \overline{W} (T_0, U_0) \right)
\]

and by taking into account (58) and (59) we obtain (55).

\[\square\]

4 An application to the existence of periodic solutions of the van der Pol equation

We end the paper by illustrating a topological degree approach, based on the above results, to investigate the existence of periodic solutions of the van der Pol equation

\[
\ddot{x} - \varepsilon (1 - x^2) \dot{x} + x = 0.
\]

Consider the compact operator \( F_\varepsilon : C ([0, 2\pi], \mathbb{R}^2) \to C ([0, 2\pi], \mathbb{R}^2) \) given by

\[
F_\varepsilon (x)(t) = x(t) - x(2\pi) - \int_0^t \left( x_2 (\tau) - x_1 (\tau) + \varepsilon (1 - x_1^2 (\tau)) x_2 (\tau) \right) d\tau,
\]

(61)
whose zeros $x = (x_1, x_2)$ correspond to $2\pi$-periodic solution $(x, \dot{x})$ of system (60). It is known (see for instance [11], § 4.6), that for $\varepsilon > 0$ sufficiently small the operator $F_\varepsilon$ has a zero $x_\varepsilon \in C([0, 2\pi], \mathbb{R}^2)$ such that

$$\|x_\varepsilon\|_{C_{2\pi}} \to 2 \text{ as } \varepsilon \to 0.$$  

Here $\| \cdot \|_{C_{2\pi}}$ denotes the norm in the Banach space $C([0, 2\pi], \mathbb{R}^2)$. We have the following result.

**Proposition 1.** For $\varepsilon > 0$ sufficiently small and $\delta \in (0, 2)$

$$\text{ind}(F_\varepsilon, W([2\pi], U_\delta)) = 0,$$

where

$$U_\delta = \{ \xi \in \mathbb{R}^2 : \|\xi\| \in (2-\delta, 2+\delta) \}.$$

**Proof.**

The proposition is a straightforward consequence of Theorem 2. In fact, if we put $\psi(t, \xi) = \begin{pmatrix} \xi_2 \\ -\xi_1 \end{pmatrix}$ and $\phi(t, \xi, \varepsilon) = \begin{pmatrix} 0 \\ (1-\xi_1^2)\xi_2 \end{pmatrix}$ then, as it can be verified, we have that

$$\Omega(t, t_0, \xi) = \begin{pmatrix} \cos(t-t_0) & \sin(t-t_0) \\ -\sin(t-t_0) & \cos(t-t_0) \end{pmatrix} \xi,$$

$$\eta(2\pi, s, \xi) - \eta(0, s, \xi) = \left( \pi - (\pi/4)(\xi_1^2 + \xi_2^2) \right) \begin{pmatrix} \xi_1 \\ \xi_2 \end{pmatrix},$$

and so (A1) and (A2) of Theorem 2 are satisfied. \hfill \Box

On the basis of the approach presented in Section 2 we now perturb the van der Pol equation by means of a higher order (with respect to $\varepsilon$) non-autonomous term to obtain, for $\varepsilon > 0$ sufficiently small, an integral operator with nonzero topological degree in a suitable open set.

In fact, consider the following perturbed system obtained from (60) by adding the forcing term $\varepsilon \sqrt{\varepsilon} \sin \left( \frac{t}{1+\varepsilon \sqrt{\varepsilon} \mu} \right)$:

$$\ddot{x} - \varepsilon (1-x^2) \dot{x} + x + \varepsilon \sqrt{\varepsilon} \sin \left( \frac{t}{1+\varepsilon \sqrt{\varepsilon} \mu} \right) = 0. \quad (63)$$

Consider the following operator $F_{\varepsilon, \mu} : C([0, 2\pi], \mathbb{R}^2) \to C([0, 2\pi], \mathbb{R}^2)$ associated to (63):

$$F_{\varepsilon, \mu}(x)(t) = x(t) - x \left( \frac{2\pi}{1+\varepsilon \sqrt{\varepsilon} \mu} \right) -$$

$$- \int_0^t \left( -x_1(\tau) + \varepsilon (1-x_1^2(\tau)) x_2(\tau) - \varepsilon \sqrt{\varepsilon} \sin \left( \frac{\tau}{1+\varepsilon \sqrt{\varepsilon} \mu} \right) \right) d\tau. \quad (64)$$
Let \( \phi_1(\xi) = \begin{pmatrix} 0 \\ (1 - \xi_1^2)\xi_2 \end{pmatrix} \), \( \phi_2(t, \xi, \varepsilon) = \begin{pmatrix} 0 \\ -\sin t \end{pmatrix} \), \( T_\mu = \frac{2\pi}{1 + \varepsilon\sqrt{\mu}} \) and define the corresponding functions \( \eta_1 \) and \( \eta_2 \).

We are now in the position to formulate the following result.

**Proposition 2.** There exists \( \mu_0 > 0 \) such that for every \( \mu \in (-\mu_0, \mu_0) \) and \( \delta \in (0!, 2) \) there exists \( \varepsilon_0 > 0 \) such that

\[
\text{deg} \left( F_{\varepsilon, \mu} W \left( T_\mu, U_{\text{max}(0, \delta)} \right) \backslash W \left( T_\mu, U_{\text{min}(0, \delta)} \right) \right) = 1!
\]

for !any! \( \varepsilon \in (0, \varepsilon_0) \).

**Proof.**

As already observed

\[\eta_1(2\pi, s, \xi) - \eta_1(0, s, \xi) = \left( \pi - (\pi/4)(\xi_1^2 + \xi_2^2) \right) \begin{pmatrix} \xi_1 \\ \xi_2 \end{pmatrix}.\]

Therefore

\[\eta_1(2\pi, s, \xi) - \eta_1(0, s, \xi) = 0, \text{ for any } s \in [0, 2\pi] \text{ and any } \xi \in \partial U_0,\]

\[\eta_1(2\pi, s, \xi) - \eta_1(0, s, \xi) \neq 0, \text{ for any } s \in [0, 2\pi], \text{ and any } \xi \in \partial U_\delta,\]

moreover

\[\text{deg}(\eta_1(2\pi, 0, \cdot), U_\delta) = 111.\]

(66)

It is also easy to see that

\[\eta_2(2\pi, s, \xi) - \eta_2(0, s, \xi) = \begin{pmatrix} 0 \\ -3\pi/4 \end{pmatrix}\]

and so

\[\text{deg}(\eta_2(2\pi, 0, \cdot), U_0) = 0.\]

(67)

By (66), (67) and Theorem 4 we obtain (65).

So the set \( W(T, U_\delta) \) contains the set \( X_{\varepsilon, \mu} \) of \( \frac{2\pi}{1 + \varepsilon\sqrt{\mu}} \)-periodic solutions of the equation (63) and the topological degree of the set \( X_{\varepsilon, \mu} \) is not equal to 0 with respect to the integral operator \( F_{\varepsilon, \mu} \) for the values \( \varepsilon, \mu \) prescribed above.

From the physical point of view the term \( \varepsilon\sqrt{\varepsilon}\sin (w_{\varepsilon, \mu}t) \) means the external voltage including in the van der Pol oscillator described by (60) (see [1]). So we have proved that \( w_{\varepsilon, \mu} = \frac{1}{1 + \varepsilon\sqrt{\mu}} \) belongs to the frequency pulling range for the forced van der Pol oscillator described by (63). This phenomena is very useful in radio engineering, but the classical form of the external voltage is \( \varepsilon \sin (w_\varepsilon t) \). Therefore our approach lets to economize the electricity!

Observe that, by a suitable choice of the function of the parameter \( \mu \) in (63), which multiplies the term \( \varepsilon\sqrt{\varepsilon} \), we can obtain any prescribed value of the topological degree in (65).
