COMPLETE INTERSECTION HOM INJECTIVE DIMENSION

SEAN K. SATHER-WAGSTAFF AND JONATHAN P. TOTUSHEK

Abstract. We introduce and investigate a new injective version of the complete intersection dimension of Avramov, Gasharov, and Peeva. It is like the complete intersection injective dimension of Sahandi, Sharif, and Yassemi in that it is built using quasi-deformations. Ours is different, however, in that we use a Hom functor in place of a tensor product. We show that (a) this invariant characterizes the complete intersection property for local rings, (b) it fits between the classical injective dimension and the G-injective dimension of Enochs and Jenda, (c) it provides modules with Bass numbers that are bounded by polynomials, and (d) it improves a theorem of Peskine, Szpiro, and Roberts (Bass’ conjecture).

1. INTRODUCTION

Convention. In Sections 1–5 let (R, m, k) be a local ring.

It is well known that R-modules with finite projective dimension are particularly nice, behaving like modules over regular local rings. Furthermore, modules of finite projective dimension have the ability to detect when the ring is regular according to the famous result of Auslander, Buchsbaum, and Serre [1, 35]. The injective dimension has similar behavior.

The complete intersection dimension of Avramov, Gasharov and Peeva [6] similarly identifies modules modules that behave like modules over over formal complete intersection rings. (The local ring R is a formal complete intersection if its m-adic completion \( \hat{R} \) is of the form \( \hat{R} \cong Q/\alpha \) where Q is a regular local ring and \( \alpha \) is generated by a Q-regular sequence.) For instance, the Betti numbers of such modules

2010 Mathematics Subject Classification. primary 13D05; secondary 13C11, 13D09, 13D22.

Key words and phrases. Bass conjecture, Bass numbers, complete intersection dimensions, injective dimension.
are bounded above by a polynomial, and these modules have the ability to detect when the ring is a formal complete intersection.

The complete intersection dimension is defined in terms of quasi-deformations of $R$, which are diagrams of local ring homomorphisms $R \xrightarrow{\varphi} R' \xleftarrow{\tau} Q$ such that $\varphi$ is flat, and $\tau$ is surjective with kernel generated by a $Q$-regular sequence. One then defines the complete intersection dimension of a finitely generated $R$-module $M$ as

$$\text{CI-dim}_R(M) = \inf \{ \text{pd}_Q(M') - \text{pd}_Q(R') \mid R \to R' \leftarrow Q \text{ is a quasi-deformation} \}$$

where $M' = R' \otimes_R M$. Sahandi, Sharif, and Yassemi [30] define the complete intersection flat dimension and complete intersection injective dimension for modules that are not necessarily finitely generated using $\text{fd}_Q(M')$ and $\text{id}_Q(M')$ in place of $\text{pd}_Q(M')$. The complete intersection injective dimension is challenging to work with because injective dimension properties often do not behave well with respect to tensor products.

In this paper we introduce and investigate the following variation on the complete intersection injective dimension

$$\text{CIHom-id}_R(M) = \inf \{ \text{id}_Q(J') - \text{pd}_Q(R') \mid R \xrightarrow{\varphi} R' \xleftarrow{\tau} Q \text{ is a quasi-deformation} \}$$

where $J' = \text{Hom}_R(R', J)$ and $J$ is an injective resolution of $M$. We call this the complete intersection Hom injective dimension.

Our first main result about this invariant is stated next. It shows how the complete intersection Hom injective dimension compares with the injective dimension and with Enochs and Jenda’s [15] Gorenstein injective dimension.

**Theorem A.** For an $R$-module $M$, there are inequalities

$$\text{Gid}_R(M) \leq \text{CIHom-id}_R(M) \leq \text{id}_R(M)$$

with equality to the left of any finite value.

This is Theorem 3.3(b) below. Theorem 3.3 also includes a version of the Chouinard formula for the complete intersection Hom injective dimension. This yields a Bass formula when $M$ is finitely generated; see Corollary 3.4.

Our next main result is contained in Theorem 5.1. It shows that the complete intersection Hom injective dimension characterizes formal complete intersection rings like the injective dimension characterizes regular rings. The subsequent result (part of Theorem 5.3) gives a polynomial bound for the Bass numbers of a finitely generated module with finite complete intersection Hom injective dimension; in the language of Avramov, Iyengar, and Miller [7] it says that such modules have finite injective complexity.

**Theorem B.** The following conditions are equivalent.

(i) $\text{CIHom-id}_R(k) < \infty$.

(ii) $R$ is a formal complete intersection.

(iii) For every $R$-module $M$, we have $\text{CIHom-id}_R(M) < \infty$.

**Theorem C.** Let $M$ be a finitely generated $R$-module with $\text{CIHom-id}_R(M) < \infty$. Then the sequence of Bass numbers $\{ \mu^i_R(M) \mid i \geq 0 \}$ is bounded above by a polynomial in $i$.

Our final main result improves Bass’ conjecture [8] as proved by Peskine, Szpiro, and Roberts [25, 28, 29]; see Theorem 5.4. It is an open question whether one can replace complete intersection Hom injective dimension with Gorenstein injective
dimension in this result [11, Question 6]; see Takahashi and Yassemi [36, 38] for progress on this question.

**Theorem D.** Assume that $R$ has non-zero finitely generated $R$-module $M$ such that $\text{CI}_{\text{Hom}} \cdot \text{id}_R(M) < \infty$. Then $R$ is Cohen-Macaulay.

In addition to the contents summarized above, Section 4 contains stability results needed for Section 5 and Appendix A contains non-local technical results for use in Section 3. Lastly, while this introduction is written in terms of modules, the body of the article is written in terms of complexes; Section 2 contains relevant background information on the derived category.

## 2. Background

Recall that $R$ is a local ring. We mostly work in the derived category $\mathcal{D}(R)$ of complexes of $R$-modules, indexed homologically (see e.g. [21, 22]). Isomorphisms in $\mathcal{D}(R)$ are identified by the symbol $\simeq$. We use the same symbol to identify quasi-isomorphisms between complexes, that is, chain maps that induce isomorphisms on the level of homology.

Let $X, Y \in \mathcal{D}(R)$. Then $\inf(X)$ and $\sup(X)$ denote the infimum and supremum, respectively, of the set $\{i \in \mathbb{Z} \mid H_i(X) = 0\}$. Let $X \otimes^L_R Y$ and $R\text{Hom}_R(X, Y)$ denote the left-derived tensor product and right-derived homomorphism complexes, respectively. The depth and width of $X$ are defined by Foxby and Yassemi [19, 37] as

$$\text{depth}_R(X) = -\sup(R\text{Hom}_R(k, X))$$
$$\text{width}_R(X) = \inf(k \otimes^L_R X).$$

The $i^{th}$ Betti number and the $i^{th}$ Bass number of $X$ are, respectively,

$$\beta_i^R(X) = \dim_k(H^i(R\text{Hom}_R(X, k))) = \dim_k(H_i(X \otimes^L_R k))$$
$$\mu_i^R(X) = \dim_k(H^i(R\text{Hom}_R(k, X))).$$

Let $E_R(k)$ denote the injective hull of $k$, and set $X^\vee = R\text{Hom}_R(X, E_R(k))$.

Let $\mathcal{D}_+(R)$ and $\mathcal{D}_-(R)$ denote the full subcategories of $\mathcal{D}(R)$ consisting of all complexes $X$ such that $H_i(X) = 0$ for $i \ll 0$ and $i \gg 0$, respectively. Set $\mathcal{D}_0(R) = \mathcal{D}_+(R) \cap \mathcal{D}_-(R)$, and let $\mathcal{D}^0(R)$ denote the full subcategory consisting of all complexes $X$ such that \( \bigoplus_{i \in \mathbb{Z}} H_i(X) \) is finitely generated.

If $X \in \mathcal{D}_-(R)$, then the injective dimension of $X$ is

$$\text{id}_R(X) = \inf \left\{ n \in \mathbb{Z} \mid X \xrightarrow{\simeq} I \text{ where } I \text{ is a complex of injective } R\text{-modules such that } I_i = 0 \text{ for all } i < -n \right\}.$$

The flat dimension (fd) and projective dimension (pd) are defined similarly for $X \in \mathcal{D}_+(R)$. If $\text{id}_R(X) < \infty$, then $X \in \mathcal{D}_0(R)$ and similarly for fd and pd.

For ease of reference we single out the following.

**Fact 2.1.** Let $S$ be a commutative noetherian ring (not necessarily local) with $\dim(S) < \infty$. If $F$ is a flat $R$-module, then $\text{pd}_S(F) \leq \dim(S) < \infty$ by Raynaud and Gruson [27, Seconde partie, Théorème (3.2.6)] and Jensen [23, Proposition 6]. In particular if $X \in \mathcal{D}_0(S)$, then $R\text{Hom}_S(F, X) \in \mathcal{D}_0(S)$.

If $X \in \mathcal{D}_+(R)$, then the complete intersection flat dimension of $X$ as defined by Sahandi, Sharif, Yassemi, and Sather-Wagstaff [30, 32] is

$$\text{CI-fd}_R(X) = \inf \{ \text{fd}_Q(X') - \text{pd}_Q(R') \mid R \to R' \leftarrow Q \text{ is a quasi-deformation} \}. $$
where $X' = R' \otimes_R^L X$. If $X \in \mathcal{D}^b_0(R)$, then this is the complete intersection dimension $CI_{-\text{dim}}(X)$ of Avramov, Gasharav, Peeva, and Sather-Wagstaff [5, 31].

Following Enochs and Jenda [15], we say that an $R$-module $N$ is Gorenstein injective if there is an exact sequence of injective modules

$$E = \cdots \to E_2 \xrightarrow{\partial_2} E_1 \xrightarrow{\partial_1} E_0 \xrightarrow{\partial_0} E_{-1} \xrightarrow{\partial_{-1}} E_{-2} \to \cdots$$

such that $N \cong \text{Ker}(\partial_0)$ and such that for any injective module $I$, the complex $\text{Hom}_R(I, E)$ is exact.

If $X \in \mathcal{D}_-(R)$, then the Gorenstein injective dimension of $X$ is

$$\text{Gid}_R(X) = \inf \left\{ n \in \mathbb{Z} \mid X \xrightarrow{\partial_n} I \text{ where } I \text{ is a complex of Gorenstein injective } R\text{-modules such that } I_i = 0 \text{ for all } i < -n \right\}.$$ 

The following concepts are due to Avramov, Christensen, and Foxby [5, 11, 17]. An $R$-complex $C \in \mathcal{D}^b_0(R)$ is semidualizing if the natural homothety morphism $\chi^R_C : R \to \text{RHom}_R(C, C)$ is an isomorphism in $\mathcal{D}(R)$. The Bass class with respect to $C$ is the class $\mathcal{B}_C(R)$ of all $X \in \mathcal{D}_0(R)$ such that $\text{RHom}_R(C, X) \in \mathcal{D}_0(R)$ and the evaluation morphism $\zeta^X_C : C \otimes_R \text{RHom}_R(C, X) \to X$ is an isomorphism in $\mathcal{D}(R)$. It is straightforward to show that $\mathcal{B}_C(R)$ satisfies the following two-of-three condition: for each distinguished triangle $X \to Y \to Z \in \mathcal{D}(R)$, if two of the three complexes are in $\mathcal{B}_C(R)$, then so is the third.

We say that $D \in \mathcal{D}^b_0(R)$ is dualizing for $R$ if it is semidualizing for $R$ and $\text{id}_R(D) < \infty$. Recall that if $R$ is a homorphic image of a Gorenstein ring, e.g., if $R$ is complete, then $R$ has a dualizing complex by [22, V.10].

A full subcategory $T \subseteq \mathcal{D}(R)$ is thick if it is closed under suspensions and summands, and it satisfies the two-of-three condition. Given any collection $S$ of $R$-complexes, the thick subcategory generated by $S$ is the smallest thick subcategory of $\mathcal{D}(R)$ containing $S$.

**Remark 2.2.** Let $R'$ be an $R$-algebra and let $T_1 = \text{Add}(R')$ be the class of $R$-module summands of arbitrary direct sums of copies of $R'$. Inductively, for $n \geq 2$ let $T_n$ consist of the objects $Z \in \mathcal{D}(R)$ such that $Z$ is a retract of an object $Y \in \mathcal{D}(R)$ such that there is an exact triangle $Y' \to Y \to Y'' \to \text{in } \mathcal{D}(R)$ with $Y' \in T_1$ and $Y'' \in T_{n-1}$. From [24, Proposition 2.3] we have $T = \bigcup_{n=1}^\infty T_n$, and furthermore if $A' \to A \to A'' \to$ is an exact triangle in $\mathcal{D}(R)$ such that $X' \in T_n$ and $X'' \in T_b$, then $X \in T_{a+b}$.

### 3. Homological Dimensions of Complexes

Recall that $R$ is a local ring. In this section we prove Theorem A from the introduction in addition to other results, e.g., a version of the Chouinard formula and Bass formula. We begin by defining the complete intersection Hom injective dimension for complexes; note that it recovers the definition for modules given in the introduction.

**Definition 3.1.** Let $X \in \mathcal{D}_-(R)$. The complete intersection Hom injective dimension of $X$ is

$$\text{CI}_{\text{Hom}, \text{id}}(X) = \inf \{ \text{id}_Q(X) - \text{pd}_Q(R') \mid R \xrightarrow{\phi} R' \xleftarrow{\phi} Q \text{ is a quasi-deformation} \}$$

where $X = \text{RHom}_R(R', X)$. 
Remark 3.2. Let $X \in D_-(R)$ be such that $\text{CI}_{\text{Hom}} \cdot \text{id}_R (X) < \infty$. Then $X \in D_0(R)$. Indeed, by assumption there is a quasi-deformation $R \xrightarrow{\varphi} R' \leftarrow Q$ such that $\text{id}_Q (X^\varphi) < \infty$. In particular $X^\varphi \in D_0(R')$, so $X \in D_0(R)$ by Corollary \[X.5\].

Furthermore $\text{CI}_{\text{Hom}} \cdot \text{id}_R (X) = -\infty$ if and only if $X \simeq 0$. Indeed, if $X \simeq 0$, then $\text{id}_R (X) = -\infty$, so using the trivial quasi-deformation $R \to R \leftarrow R$ we have $\text{CI}_{\text{Hom}} \cdot \text{id}_R (X) = -\infty$. Conversely, assume that $\text{CI}_{\text{Hom}} \cdot \text{id}_R (X) = -\infty$. It follows that there is a quasi-deformation $R \xrightarrow{\hat{\varphi}} R' \leftarrow Q$ such that $\text{id}_Q (X^\varphi) = -\infty$. Thus, we have $\text{RHom}_R (R', X) = X^\varphi \simeq 0$. Since $R'$ is faithfully flat over $R$, it follows from, e.g., \[34\] Lemma 5.6] that $X \simeq 0$, as desired.

The following result contains Theorem \[A\] from the introduction and our version of the Chouinard formula. Furthermore, it shows that any quasi-deformation that detects the finiteness of $\text{CI}_{\text{Hom}} \cdot \text{id}_R (X)$ can be used to calculate the actual value of $\text{CI}_{\text{Hom}} \cdot \text{id}_R (X)$. See Example \[5.2\] for some strict inequalities in part \(b\).

**Theorem 3.3.** Let $X \in D_0(R)$.

(a) If $\text{CI}_{\text{Hom}} \cdot \text{id}_R (X) < \infty$, then for any quasi-deformation $R \xrightarrow{\hat{\varphi}} R' \leftarrow Q$ such that $\text{id}_Q (X^\varphi) < \infty$ we have

\[
\text{CI}_{\text{Hom}} \cdot \text{id}_R (X) = \text{id}_Q (X^\varphi) - \text{pd}_Q (R') = \sup \{ \text{depth}(R_p) - \text{width}_{R_p} (X_p) \mid p \in \text{Spec}(R) \}.
\]

(b) There are inequalities

\[
\text{Gid}_R (X) \leqslant \text{CI}_{\text{Hom}} \cdot \text{id}_R (X) \leqslant \text{id}_R (X)
\]

with equality to the left of any finite value.

**Proof:** We will prove \(a\) and \(b\) simultaneously.

Claim 1: If $\text{id}_R (X) < \infty$, then $\text{CI}_{\text{Hom}} \cdot \text{id}_R (X) = \text{id}_R (X) < \infty$. To this end, let $R \xrightarrow{\varphi} R' \leftarrow Q$ be a quasi-deformation. Since $R'$ is faithfully flat over $R$, from \[13\] Theorem 2.2 we have $\text{id}_{R'} (X^\varphi) = \text{id}_R (X) < \infty$. We next observe that

\[
\text{id}_Q (X^\varphi) - \text{pd}_Q (R') \leqslant \text{id}_{R'} (X^\varphi) = \text{id}_R (X) < \infty
\]

by \[13\] Corollary 4.2(b)(I). Thus, to establish the claim, it remains to verify the first inequality here is an equality.

The Chouinard formula \[13\] Corollary 3.1 and \[37\] Theorem 2.10] states

\[
\text{id}_{R'} (X^\varphi) = \sup \{ \text{depth}(R'_p) - \text{width}_{R'_p} ((X^\varphi)_p) \mid p \in \text{Spec}(R') \}.
\] (3.3.1)

Let $p \in \text{Spec}(R')$ be such that $\text{id}_{R'} (X^\varphi) = \text{depth}(R'_p) - \text{width}_{R'_p} ((X^\varphi)_p)$, and set $q = \tau^{-1} (p) \in \text{Spec}(Q)$. Since $\tau : Q \to R'$ is a codimension-$c$ deformation where $c = \text{pd}_Q (R')$ so is $\tau_p : Q_q \to R'_p$. Thus we have $\text{depth}(Q_q) = \text{depth}(R'_p) + c$. This explains the second equality in the following display:

\[
\text{id}_Q (X^\varphi) \leqslant \text{id}_{R'} (X^\varphi) + \text{pd}_Q (R')
\]

\[
= \text{depth}(R'_p) - \text{width}_{R'_p} ((X^\varphi)_p) + \text{pd}_Q (R')
\]

\[
= \text{depth}(Q_q) - \text{width}_{Q_q} ((X^\varphi)_q) - \text{pd}_Q (R') + \text{pd}_Q (R')
\]

\[
\leqslant \sup \{ \text{depth}(Q_q) - \text{width}_{Q_q} ((X^\varphi)_q) \mid q \in \text{Spec}(Q) \}
\]

\[
= \text{id}_Q (X^\varphi).
\]
The first inequality is from the preceding paragraph, and the first equality is from our choice of $p$. The second inequality is tautological and the last equality is from the Chouinard formula \[3.3.1\]. This establishes Claim 1.

For the rest of the proof, assume that $\text{CI}_{\text{Hom}} - \text{id}_R(X) < \infty$, and let $R \xrightarrow{\varphi} R' \leftarrow Q$ be a quasi-deformation such that $\text{id}_Q(X) < \infty$.

Claim 2: $\text{Gid}_R(X) = \text{Gid}_R(X^\varphi) < \infty$. By \[14\] Theorem A to verify Claim 2, it suffices to show that $\text{Gid}_R(X) < \infty$.

Case 1: $Q$ is complete. Then $Q$ has a dualizing complex $D^Q$. Since $\tau$ is a deformation, the complex $D^R = R' \otimes_Q^L D^Q$ is dualizing for $R'$ by \[31\] (5.1) Theorem]. Since $\text{id}_Q(X) < \infty$, we have $X^\varphi \in B_{D^Q}(Q)$ by \[3\] (3.2) Theorem. Hence \[5\] (7.9) Corollary] implies $X^\varphi \in B_{D^{R'}(R')}$, so \[12\] Theorem 4.4] yields $\text{Gid}_R(X^\varphi) < \infty$.

Case 2: General case. There are equalities:

$$\text{id}_Q(X^\varphi) = \text{id}_Q(\text{RHom}_Q(Q, X^\varphi)) = \text{id}_Q(\text{RHom}_{R'}(\hat{R}', X^\varphi))$$

where the first equality is by \[13\] Theorem 2.2] and the second equality is by the isomorphism $\text{RHom}_Q(Q, X^\varphi) \cong \text{RHom}_{R'}(\hat{R}', X^\varphi)$ in $D(\hat{Q})$. Hence Case 1 explains the finiteness in the next display,

$$\text{Gid}_R(X^\varphi) = \text{Gid}_{\hat{R}'}(\text{RHom}_{R'}(\hat{R}', X^\varphi)) < \infty.$$ 

The equality is from \[14\] Proposition 3.6]. This establishes Claim 2.

To complete the proof, in the following display the first equality is Chouinard’s formula \[37\] Theorem 2.10]:

$$\text{id}_Q(X^\varphi) - \text{pd}_Q(R') = \sup\{\text{depth}(Q_q) - \text{width}_{Q_p}(X^\varphi)_q \mid q \in \text{Spec}(Q)\} - \text{pd}_Q(R')$$

$$= \sup\{\text{depth}(R'_q) - \text{width}_{R'_p}(X^\varphi)_p \mid p \in \text{Spec}(R')\}$$

$$= \text{Gid}_R(X^\varphi)$$

$$= \text{Gid}_R(X)$$

$$= \sup\{\text{depth}(R_p) - \text{width}_{R_p}(X_p) \mid p \in \text{Spec}(R)\}.$$ 

The second equality is established as in the proof of Claim 1. The third and fifth equalities are by the version of Chouinard’s formula for Gorenstein injective dimension \[14\] Theorem C]. The fourth equality is by Claim 2. Notice that this sequence shows that the value $\text{id}_Q(X^\varphi) - \text{pd}_Q(R')$ is independent of the choice of quasi-deformation as long as $\text{id}_Q(X^\varphi) < \infty$. Thus, the display justifies the remaining conclusions in the theorem.

Theorem \[5\] states that if $M$ is a non-zero finitely generated $R$-module of finite injective dimension, then $\text{id}_R(M) = \text{depth}(R)$. The next result is a version of this for complexes of finite complete intersection Hom injective dimension.

**Corollary 3.4.** Let $X \in D^f_b(R)$ be such that $\text{CI}_{\text{Hom}} - \text{id}_R(X) < \infty$. Then

$$\text{CI}_{\text{Hom}} - \text{id}_R(X) = \text{depth}(R) - \text{inf}(X).$$

**Proof:** Theorem \[3.3\] explains the first equality in the following display.

$$\text{CI}_{\text{Hom}} - \text{id}_R(X) = \text{Gid}_R(X) = \text{depth}(R) - \text{inf}(X)$$

The second equality is by \[14\] Corollary 2.3].

If $X \in D_b(R)$ has $\text{id}_R(X) < \infty$, then $\text{id}_R(X) \leq -\text{inf}(X)$ by definition. Our next corollary is a version of this for the complete intersection Hom injective dimension.
**Corollary 3.5.** Let $X \in \mathcal{D}_b(R)$ be such that $\text{CI}_{\text{Hom}} \cdot \text{id}_R(X) < \infty$. Then one has $\text{CI}_{\text{Hom}} \cdot \text{id}_R(X) \leq -\inf(X)$.

**Proof:** The condition $\text{CI}_{\text{Hom}} \cdot \text{id}_R(X) < \infty$ implies that $\text{CI}_{\text{Hom}} \cdot \text{id}_R(X) = \text{Gid}_R(X) \leq -\inf(X)$ by Theorem 3.3 and the definition of Gid. □

The next result is dual to [32, Theorem F]. It shows that one can exert a certain amount of control over the properties of quasi-deformations that detect the finiteness of $\text{CI}_{\text{Hom}} \cdot \text{id}_R(X)$.

**Theorem 3.6.** Let $X \in \mathcal{D}_b(R)$ be such that $\text{CI}_{\text{Hom}} \cdot \text{id}_R(X) < \infty$. Then there exists a quasi-deformation $R \xrightarrow{\varphi} R' \leftarrow Q$ such that $R'$ and $Q$ are complete, the closed fibre $R'/mR'$ is artinian and Gorenstein, and $\text{CI}_{\text{Hom}} \cdot \text{id}_R(X) = \text{id}_Q(X^{\varphi}) - \text{pd}_Q(R')$.

**Proof:** There is a quasi-deformation $R \xrightarrow{\tilde{\varphi}} R' \xleftarrow{\tau} Q$ such that $\text{id}_Q(X^{\tilde{\varphi}}) < \infty$. Let $P \in \text{Min}(R'/mR')$ and $p = \tau^{-1}(P)$. Then the diagram $R \rightarrow R'_P \leftarrow Q_p$ is a quasi-deformation such that the closed fibre $R'_P/mR'_P \cong (R'/mR')_P$ artinian. We now have the following commutative diagram:

$$
\begin{array}{ccc}
Q & \longrightarrow & Q_p \\
\tau \downarrow & & \downarrow \\
R & \overset{\varphi}{\longrightarrow} & R'_P \\
\end{array}
$$

where the horizontal maps are flat. Lemma A.1 explains the inequality (∗) in the next display; the equality is by Hom-tensor adjointness and tensor cancellation.

$$
\text{id}_{Q_p}(R\text{Hom}_R(R'_P, X)) = \text{id}_{Q_p}(R\text{Hom}_{R'}(R'_P, X^{\varphi})) \overset{(∗)}{\leq} \text{id}_Q(X^{\varphi}) < \infty
$$

By replacing $R \rightarrow R' \leftarrow Q$ with $R \rightarrow R'_P \leftarrow Q_p$ we assume that the quasi-deformation $R \rightarrow R' \leftarrow Q$ has $R'/mR'$ artinian.

By [32, Lemma 3.1] there is a commutative diagram of local ring homomorphisms

$$
\begin{array}{ccc}
R & \overset{\varphi}{\longrightarrow} & R' & \rightarrow & Q \\
\downarrow & & \downarrow & & \downarrow \\
R'' & \longrightarrow & Q' & \leftarrow & Q
\end{array}
$$

such that $R''$ and $Q'$ are complete, and the diagram $R \rightarrow R'' \leftarrow Q$ is a quasi-deformation such that $R''/mR''$ is Gorenstein and artinian.

Consider the right square of the above diagram. As in the earlier part of the proof, Lemma A.1 implies that

$$
\text{id}_{Q'}(R\text{Hom}_R(R'', X)) = \text{id}_{Q'}(R\text{Hom}_{R''}(R'', X^{\varphi})) \overset{(†)}{\leq} \text{id}_Q(X^{\varphi}) < \infty.
$$

The desired result now follows from Theorem 3.3. □

**Remark 3.7.** There is a subtlety in the proof of Theorem 3.6 that merits attention. Specifically, the inequalities (∗) and (†) do not follow directly from simple Hom-tensor adjointness arguments. A similar subtlety occurs in the proof of [32, Theorem F], though the author was unaware of it at the time; our Lemma A.2 addresses this.
If $X \in \mathcal{D}_b(R)$ has $\text{id}_R(X) < \infty$, then $X$ is in the Bass class $\mathcal{B}_C(R)$ with respect to every semidualizing $R$-complex $C$ by [10] (4.4) Proposition; see the end of Section 2 for relevant relevant definitions. Note that we do not know if this conclusion holds if one only assumes $\text{Gid}_R(X) < \infty$, unless $C$ is dualizing. On the other hand, the following result shows that this conclusion does hold if $\text{CI}_{\text{Hom}}$-$\text{id}_R(X) < \infty$.

**Theorem 3.8.** Let $X \in \mathcal{D}_b(R)$ be such that $\text{CI}_{\text{Hom}}$-$\text{id}_R(X) < \infty$. Then $X \in \mathcal{B}_C(R)$ for every semidualizing $R$-complex $C$.

**Proof:** Theorem 3.6 provides a quasi-deformation $R \xrightarrow{\varphi} R' \xleftarrow{\tau} Q$ such that $Q$ is complete and the closed fibre $R'/mR'$ is artinian and Gorenstein such that $\text{id}_Q(X^e) < \infty$. Since $R'$ is flat over $R$, the $R'$-complex $C' = R' \otimes_R C$ is semidualizing by [10] (5.3) Proposition. Furthermore, since $Q$ is complete, from [20] Proposition 4.2 there exists a semidualizing $Q$ complex $B$ such that $C' \simeq R' \otimes_B B$. As $\text{id}_Q(X^e) < \infty$, we have $X^e \in \mathcal{B}_B(Q)$. Apply [10] Proposition 5.3 to conclude that $X^e \in \mathcal{B}_B(R') = \mathcal{B}_C(R')$ and $X^e \in \mathcal{B}_C(R)$.

Note that $\mathcal{B}_C(R)$ is not closed under arbitrary products. However, it is straightforward to show that if $Y \in \mathcal{B}_C(R)$, then the product $Y^\Lambda$ is in $\mathcal{B}_C(R)$ for any (possibly infinite) index set $\Lambda$; the point here is that $Y \in \mathcal{B}_C(R)$ implies $Y \in \mathcal{D}_b(R)$ which implies in turn $Y^\Lambda \in \mathcal{D}_b(R)$. In particular, we have

$$\mathbf{R}\text{Hom}_R((R')^\Lambda, X) \cong \mathbf{R}\text{Hom}_R(R', X)^\Lambda = (X^e)^\Lambda \in \mathcal{B}_C(R).$$

Since $\mathcal{B}_C(R)$ is closed under summands, it follows that $\mathbf{R}\text{Hom}_R(T, X) \in \mathcal{B}_C(R)$ for all $T \in \text{Add}(R') = T_1$, using the notation from Remark 2.2. Since $\mathcal{B}_C(R)$ satisfies the two-of-three condition, it follows by induction on $n$ that $\mathbf{R}\text{Hom}_R(T, X) \in \mathcal{B}_C(R)$ for all $T \in T_n$, therefore for all $T$ in the thick subcategory generated by $\text{Add}(R')$. In particular, $X \simeq \mathbf{R}\text{Hom}_R(R, X) \in \mathcal{B}_C(R)$ by Proposition A.3.

Our next result documents co-localization behavior of the complete intersection Hom injective dimension.

**Proposition 3.9.** Let $X \in \mathcal{D}_b(R)$, and let $(p) \subseteq \text{Spec}(R)$. Then there is an inequality $\text{CI}_{\text{Hom}}$-$\text{id}_{R_p}( \mathbf{R}\text{Hom}_R(R_p, X) ) \leq \text{CI}_{\text{Hom}}$-$\text{id}_R(X)$.

**Proof:** Fact 2.1 implies that $\text{pd}_R(R_p) < \infty$. Thus, the condition $X \in \mathcal{D}_b(R)$ guarantees that $\mathbf{R}\text{Hom}_R(R_p, X) \in \mathcal{D}_b(R)$.

Assume without loss of generality that $\text{CI}_{\text{Hom}}$-$\text{id}_R(X) < \infty$. By definition, there is a quasi-deformation $R \xrightarrow{\varphi} R' \xleftarrow{\tau} Q$ such that $\text{id}_Q(X^e) < \infty$.

Since $R'$ is faithfully flat over $R$, there is a prime ideal $p' \subseteq \text{Spec}(R')$ lying over $p$. Set $p = \tau^{-1}(p') \subseteq \text{Spec}(Q)$. This yields the following commutative diagram of ring homomorphisms.

$$
\begin{array}{ccc}
R & \xrightarrow{\varphi} & R' \\
| & & | \\
R_p & \xrightarrow{\varphi_p} & R_p' \\
| & & | \\
& Q & \xrightarrow{\tau_p} \mathbf{Q}_p \\
\end{array}
$$

Note that the rings in this diagram are local, as are the horizontal homomorphisms, but the vertical maps are not local.
Lemma $\text{A.1}$ explains the second step in the next sequence
\[
\text{id}_Q(X^\varphi) = \text{id}_Q(R\text{Hom}_R(R', X)) \\
\geq \text{id}_{Q'}(R\text{Hom}_R(R'_p, R\text{Hom}_R(R', X))) \\
= \text{id}_{Q'}(R\text{Hom}_R(R'_p, R\text{Hom}_R(R_p, X))).
\]
The first step is by definition, and the third step is from Hom-tensor adjointness. The bottom row of the above diagram is a quasi-deformation. So, the preceding display implies that $\text{CI}_{\text{Hom}} - \text{id}_{R_p}(R\text{Hom}_R(R_p, X)) < \infty$. Furthermore, Theorem $\text{3.3}^{(m)}$ provides
\[
\text{CI}_{\text{Hom}} - \text{id}_R(X) = \text{id}_Q(X^\varphi) - \text{pd}_Q(R') \\
\geq \text{id}_{Q'}(R\text{Hom}_R(R'_p, R\text{Hom}_R(R_p, X))) - \text{pd}_{Q'}(R'_p) \\
= \text{CI}_{\text{Hom}} - \text{id}_{R_p}(R\text{Hom}_R(R_p, X))
\]
as desired. □

At this point we do not understand the localization behaviour of the complete intersection Hom injective dimension. So we pose the following.

**Question 3.10.** If $X \in \mathcal{D}_b(R)$ and $p \in \text{Spec}(R)$, must we have $\text{CI}_{\text{Hom}} - \text{id}_{R_p}(X_p) \leq \text{CI}_{\text{Hom}} - \text{id}_R(X)$?

A frustrating question about the complete intersection dimension is the so called two-of-three question: if two modules in a short exact sequence have finite complete intersection dimension, must the third one as well? (The difficulty stems from the presence of two potentially incomparable quasi-deformations.) This question is easy to answer if one of the modules has finite projective dimension. The analogous question for complete intersection Hom injective dimension is similarly frustrating. The next lemma deals with a special case. The interested reader can rotate the given triangle to obtain two minor variations of the lemma.

**Lemma 3.11.** Let $A \rightarrow B \rightarrow C \rightarrow$ be an exact triangle in $\mathcal{D}_b(R)$. Assume that $\text{id}_R(A) < \infty$.

(a) Let $R \xrightarrow{\varphi} R' \leftarrow Q$ be a quasi-deformation. Then $\text{id}_Q(B^\varphi) < \infty$ if and only if $\text{id}_Q(C^\varphi) < \infty$.

(b) $\text{CI}_{\text{Hom}} - \text{id}_R(B) < \infty$ if and only if $\text{CI}_{\text{Hom}} - \text{id}_R(C) < \infty$.

**Proof:** (a) As $\text{id}_R(A) < \infty$, the proof of Theorem $\text{3.3}$ Claim 1 implies that $\text{id}_Q(A^\varphi) < \infty$. The two-of-three condition for injective dimension now implies that $\text{id}_Q(B^\varphi) < \infty$ if and only if $\text{id}_Q(C^\varphi) < \infty$ as desired.

Part (b) follows from (a) via the definition of $\text{CI}_{\text{Hom}} - \text{id}$. □

Readers may be disturbed by the fact that the complete intersection Hom injective dimension of a module seems to require $R\text{Hom}$ or at least a Hom-complex. Here we show how to avoid these in the task of detecting finiteness of the complete intersection Hom injective dimension. The basic idea is to take a high co-syzygy.

**Proposition 3.12.** Let $X \in \mathcal{D}_b(R)$, and fix an injective resolution $X \xrightarrow{\varphi} I$ with $I_i = 0$ for all $i > s$. Fix an integer $j \leq \inf(X) - \dim(R)$, and set $N = \text{Im}(\partial^j_f)$.

(a) Let $R \xrightarrow{\varphi} R' \leftarrow Q$ be a quasi-deformation. The following are equivalent.

(i) $\text{id}_Q(X^\varphi) < \infty$
(ii) \( \text{id}_Q(N^\varphi) < \infty \)
(iii) \( \text{id}_Q(\text{Hom}_R(R', N)) < \infty \)

(b) Then one has \( \text{CI}_{\text{Hom}} \cdot \text{id}_R(M) < \infty \) if and only if there is a quasi-deformation \( R \to R' \leftarrow Q \) such that \( \text{id}_Q(\text{Hom}_R(R', N)) < \infty \).

**Proof:** Consider the following “hard truncation” of \( I \)
\[
I' = 0 \to I_s \to \cdots \to I_j \to 0
\]
which has \( \text{id}_R(I') < \infty \).

(i) \( \Leftrightarrow \) (ii) Our assumptions provide an exact triangle \( I' \to \Sigma^j N \to X \to \) in \( D(R) \), so Lemma 3.11(a) implies the desired equivalence.

(ii) \( \Leftrightarrow \) (iii) Fact 2.1 implies \( \text{pd}_R(R') \leq \dim(R) < \infty \), so
\[
\inf(\text{Hom}_R(R', I)) = \inf(\text{RHom}_R(R', X)) \geq \inf(X) - \dim(R) \geq j
\]
by \([3, 2.4.5. \text{Theorem}]\). Since the truncation
\[
0 \to I_{j-1} \to I_{j-2} \to \cdots
\]
is an injective resolution of \( N \), it follows that \( \text{Ext}_R^{\geq 1}(R', N) = 0 \), so
\[
N^\varphi = \text{RHom}_R(R', N) \simeq \text{Hom}_R(R', N).
\]
The desired equivalence now follows.

Part (b) follows from part (a) by definition. \( \square \)

4. **Stability Results**

Recall that \( R \) is a local ring. This section consists of stability results used in Section 5 to prove Theorems B–D from the introduction.

**Proposition 4.1.** Let \( X, J \in \mathcal{D}_b(R) \). Then
\[
\text{CI}_{\text{Hom}} \cdot \text{id}_R(\text{RHom}_R(X, J)) \leq \text{CI-fd}_R(X) + \text{id}_R(J) \tag{4.1.1}
\]
with equality holding when \( J \) is a faithfully injective \( R \)-module, i.e., when \( J \) is an injective \( R \)-module with \( E_R(k) \) as a summand. In particular, \( \text{CI}_{\text{Hom}} - \text{id}_R(X^\vee) \) and \( \text{CI-fd}_R(X) \) are simultaneously finite.

**Proof:** Assume without loss of generality that \( \text{id}_R(J) < \infty \). Consider an arbitrary quasi-deformation \( \overset{\varphi}{\varphi} \to R' \leftarrow Q \). There are isomorphisms
\[
\text{RHom}_R(X, J)^\varphi = \text{RHom}_R(R' \cdot \overset{L}{\text{L}} R X, J)
\]
\[
\simeq \text{RHom}_R(R' \cdot \overset{L}{\text{L}} R X, J)
\]
\[
\simeq \text{RHom}_R(R' \cdot \overset{L}{\text{L}} R (R' \cdot \overset{L}{\text{L}} R X), J)
\]
\[
\simeq \text{RHom}_R(R' \cdot \overset{L}{\text{L}} R X, \text{RHom}_R(R', J))
\]
\[
= \text{RHom}_R(X', J^\varphi)
\]
where the first and third isomorphisms are by Hom-tensor adjointness, and the second isomorphism is by tensor-cancellation.
For the inequality (4.1.1), assume without loss of generality for this paragraph that CI-id_Q(X) = fd_Q(X') − pd_Q(R') < ∞. This explains the second equality in the next display; the first equality is by the preceding paragraph.

\[
\text{id}_Q(\text{RHom}_R(X, J)^\circ) - \text{pd}_Q(R') = \text{id}_Q(\text{RHom}_R(X', J^\circ)) - \text{pd}_Q(R') \\
\leq \text{fd}_Q(X') + \text{id}_R(J^\circ) - \text{pd}_Q(R') \\
= \text{CI-fd}_R(X) + \text{id}_R(J^\circ) \\
= \text{CI-fd}_R(X) + \text{id}_R(J)
\]

The inequality is from [6, Theorem 4.1(I)], and the last equality is by the proof of Claim 1 in Theorem 3.3. This verifies inequality (4.1.1).

For the remainder of the proof assume that J is a faithfully injective R-module. In this case Jϕ is a faithfully injective R'-module. We need to show that inequality (4.1.1) is an equality. To this end assume without loss of generality that CI_Hom-id_R(\text{RHom}_R(X, J)) = id_Q(\text{RHom}_R(X', J^\circ)) - \text{pd}_Q(R') < ∞. The proof of [6, Theorem 4.1(I)] shows that the inequality in the preceding display is actually an equality. The desired equality now follows as in the preceding paragraph. The statement about simultaneous finiteness is a direct consequence.

□

Our next result complements [32, Proposition 4.4(a)]. It is the final key we need to prove Theorem 4.5 below.
Lemma 4.4. Let $Y \in \mathcal{D}_b(R)$ be such that $H(Y)$ is $m$-torsion. Let $K = K^R(x)$ be the Koszul complex over $x = x_1, \ldots, x_n \in m$. Then

$$\text{CI-fd}_R(K \otimes_R L Y) = \text{CI-fd}_R(Y) + n = \text{CI-fd}_R(Y) + \text{pd}_R(K).$$

In particular, $\text{CI-fd}_R(K \otimes_R L Y)$ and $\text{CI-fd}_R(Y)$ are simultaneously finite.

Proof: Consider a quasi-deformation $R \xrightarrow{\varphi} R' \xleftarrow{\psi} Q$ such that the closed fibre of $\varphi$ is artinian. Note that [32, Theorem F] shows that $\text{CI-fd}_R(Y)$ is the infimum of the set of quantities $\text{fd}_Q(Y') - \text{pd}_Q(R')$ ranging through all such quasi-deformations; and similarly for $\text{CI-fd}_R(K \otimes_R L Y)$.

For $i = 1, \ldots, n$, let $x'_i = \varphi(x_i)$, and choose $y_i \in Q$ such that $\tau(y_i) = x'_i$. It is straightforward to verify that

$$(K \otimes_R L Y)' \simeq K^R(x') \otimes_R L Y' \simeq K^Q(y) \otimes_R L Y'$$

in $\mathcal{D}_b(Q)$. Furthermore, from the assumption that $R'/mR'$ is artinian, it is straightforward to show that $H(Y')$ is $m'$-torsion where $m'$ is the maximal ideal of $R'$. Hence $H(Y')$ is $n$-torsion where $n$ is the maximal ideal of $Q$. From [26 Corollary 4.32] and [14 Proposition 5.4] the “small support”

$$\text{supp}_Q(Y') = \{ p \in \text{Spec}(Q) \mid \kappa(p) \otimes_R L Y' \not\simeq 0 \}$$

is contained in $\{n\}$. Thus [33 Lemma 3.4] implies that

$$\text{fd}_Q((K \otimes R L Y)') = \text{fd}_Q(K^Q(y) \otimes_R L Y') = \text{fd}_Q(Y') + n.$$ 

Subtract $\text{pd}_Q(R')$ from the display and take an infimum to obtain the desired equality. The statement about simultaneous finiteness follows directly. \qed

Next we have the main result for this section. We use it extensively in Section 5.

Theorem 4.5. Let $X \in \mathcal{D}_b^!(R)$.

(a) Then $\text{CI-fd}_R(X^\vee) \leq \text{CI}_{\text{Hom}} \text{-id}_R(X)$.

(b) If in addition $H_i(X)$ is Matlis reflexive (e.g., has finite length) for all $i$, then $\text{CI-fd}_R(X^\vee) = \text{CI}_{\text{Hom}} \text{-id}_R(X)$; in particular, in this case $\text{CI}_{\text{Hom}} \text{-id}_R(X)$ and $\text{CI-fd}_R(X^\vee)$ are simultaneously finite.

Proof: Assume that each $H_i(X)$ is Matlis reflexive. Then the natural biduality map $H_i(X) \to H_i(X^{\vee \vee})$ is an isomorphism for all $i$. It follows that $X \simeq X^{\vee \vee}$, so

$$\text{CI}_{\text{Hom}} \text{-id}_R(X) = \text{CI}_{\text{Hom}} \text{-id}_R(X^{\vee \vee}) = \text{CI-fd}_R(X^\vee)$$

by Proposition 4.1.

Let $K = K^R(x)$ be the Koszul complex where $x = x_1, \ldots, x_n \in m$ is a generating sequence for $m$. Since $X \in \mathcal{D}_b^!(R)$, the dual $X^\vee \in \mathcal{D}_b(R)$ has $m$-torsion homology. Thus Lemma 4.3 explains the first equality in the following display.

$$\text{CI-fd}_R(X^\vee) = \text{CI-fd}_R(K \otimes_R L (X^\vee)) - \text{pd}_R(K)$$

$$= \text{CI-fd}_R(R\text{Hom}_R(K, X)^\vee) - \text{pd}_R(K)$$

$$= \text{CI}_{\text{Hom}} \text{-id}_R(R\text{Hom}_R(K, X)) - \text{pd}_R(K)$$

$$\leq \text{CI}_{\text{Hom}} \text{-id}_R(X)$$

The second equality is by the Hom-evaluation isomorphism $R\text{Hom}_R(K, X)^\vee \simeq K \otimes_R L (X^\vee)$. The third equality is by part (1) as $H(R\text{Hom}_R(K, X))$ has finite length. The inequality is by Proposition 4.3. \qed
5. Complete Intersection and Cohen-Macaulay Properties

Recall that $R$ is a local ring. In this section we prove Theorems \[ \text{3}\] \[ \text{1}\] from the introduction starting with Theorem \[ \text{3}\] \[ \text{1}\]. Recall that the term “formal complete intersection” is defined in the introduction.

**Theorem 5.1.** The following conditions are equivalent.

(i) $\text{CI}_{\text{Hom}} - \text{id}_R(k) < \infty$.
(ii) $R$ is a formal complete intersection.
(iii) For every $Y \in D_b(R)$, we have $\text{CI}_{\text{Hom}} - \text{id}_R(Y) < \infty$.

**Proof:** The implication (iii) $\Rightarrow$ (i) is trivial.

(i) $\Rightarrow$ (ii) Assume that $\text{CI}_{\text{Hom}} - \text{id}_R(k) < \infty$. Then Theorem \[ \text{4}\] \[ \text{5}\] explains the third equality in the next display while the second equality is from the isomorphisms $k^\vee \cong \text{Hom}_R(k, E_R(k)) \cong k$.

$$\text{CI-dim}(k) = \text{CI-fd}_R(k) = \text{CI-fd}_R(k^\vee) = \text{CI}_{\text{Hom}} - \text{id}_R(k) < \infty$$

By \[ \text{3}\] \[ \text{1}\] Theorem 1.3 it follows that $R$ is a formal complete intersection.

(ii) $\Rightarrow$ (iii) Assume that $R$ is a formal complete intersection and $Y \in D_b(R)$. By definition $\hat{R} \cong Q/I$ where $Q$ is a regular local ring and $I$ is generated by a $Q$-regular sequence. Therefore the natural maps $R \xrightarrow{\varphi} \hat{R} \leftarrow Q$ form a quasi-deformation. By Fact \[ \text{2}\] \[ \text{1}\] the condition $Y \in D_b(R)$ implies $Y^\varphi \in D_b(R^\varphi)$, hence $Y^\varphi \in D_b(Q)$. As $Q$ is regular, we have that $\text{id}_Q(Y^\varphi) < \infty$ by \[ \text{3}\] \[ \text{1}\] \[ \text{ Proposition 3.1}\]. Thus $\text{CI}_{\text{Hom}} - \text{id}_R(Y) < \infty$. \[ \square \]

Here is the example promised before Theorem \[ \text{3}\] \[ \text{3}\].

**Example 5.2.** If $R$ is Gorenstein and not a formal complete intersection, then $\text{Gid}_R(k) = \dim(R) < \infty = \text{CI}_{\text{Hom}} - \text{id}_R(k)$. On the other hand, if $R$ is a formal complete intersection but not regular, then $\text{CI}_{\text{Hom}} - \text{id}_R(k) = \dim(R) < \infty = \text{id}_R(k)$.

The following contains Theorem \[ \text{4}\] \[ \text{3}\] from the introduction.

**Theorem 5.3.** Let $X \in D_b(R)$ be such that $\mu_i^R(X) < \infty$ for all $i$, e.g., $X \in D^f_b(R)$. If $\text{CI}_{\text{Hom}} - \text{id}_R(X) < \infty$, then the sequence of Bass numbers $\{\mu_i^R(X) \mid i \geq -\sup(X)\}$ is bounded above by a polynomial in $i$.

**Proof:** Assume $\text{CI}_{\text{Hom}} - \text{id}_R(X) < \infty$. Theorem \[ \text{4}\] \[ \text{5}\] implies $\text{CI-fd}_R(X^\vee) < \infty$. It is straightforward to show that $\beta_i^R(X^\vee) = \mu_i^R(X) < \infty$. As in the proof of \[ \text{1}\] \[ \text{Lemma 1.5}\] the sequence of Betti numbers $\{\beta_i^R(X^\vee) \mid i \geq \inf(X^\vee) = -\sup(X)\}$ is bounded above by a polynomial in $i$, so we have the desired conclusion. \[ \square \]

The following is Theorem \[ \text{1}\] \[ \text{7}\] from the introduction.

**Theorem 5.4.** Assume that $R$ has non-zero finitely generated $R$-module $M$ such that $\text{CI}_{\text{Hom}} - \text{id}_R(M) < \infty$. Then $R$ is Cohen-Macaulay.

**Proof:** Theorem \[ \text{4}\] \[ \text{5}\] implies $\text{CI-fd}_R(M^\vee) < \infty$. Therefore by \[ \text{3}\] \[ \text{2}\] \[ \text{Theorem F}\] there is a quasi-deformation $R \xrightarrow{\varphi} R' \leftarrow Q$ such that $R'$ and $Q$ are complete, and the closed fibre of $\varphi$ is artinian and Gorenstein, and $\text{fd}_Q((M^\vee)^\varphi) < \infty$. The restrictions on $\varphi$ imply that $E_R(k)^\varphi \cong E_{R'}(l)$ by \[ \text{13}\] \[ \text{Theorem 1}\], where $l$ is the
residue field of \( R' \); so
\[
(M')' = R' \otimes_R^L \text{Hom}_R(M, E_R(k)) \\
\simeq \text{Hom}_{R'}(R' \otimes_R^L M, R' \otimes_R^L E_R(k)) \\
\simeq \text{Hom}_{R'}(M', E_{R'}(l)).
\]
Thus \( \text{fd}_Q(\text{Hom}_{R'}(M', E_{R'}(l))) < \infty \). Notice that \( M' \) is a finitely generated module over the complete local ring \( R' \). Therefore it is Matlis reflexive over \( R' \). From [3, Theorem 4.1(I)] we have
\[
\text{id}_Q(M') = \text{id}_Q(\text{Hom}_{R'}(\text{Hom}_{R'}(M', E_{R'}(l)), E_{R'}(l))) < \infty.
\]
In conclusion \( Q \) has a non-zero finitely generated module \( M' \) of finite injective dimension. Thus \( Q \) is Cohen-Macaulay by Bass’ conjecture, which implies that \( R' \) and \( R \) are Cohen-Macaulay.

\section*{Appendix A. Derived Functors}

The first result in this appendix is for use in Theorem 3.6 and Proposition 3.9.

\textbf{Lemma A.1.} Let \( R, S, \tilde{R}, \tilde{S} \) be commutative noetherian rings (not necessarily local) and consider the following commutative diagram of ring homomorphisms
\[
\begin{array}{ccc}
R & \xrightarrow{\beta} & \tilde{R} \\
\downarrow{\tau} & & \downarrow{\tilde{\tau}} \\
S & \xrightarrow{\gamma} & \tilde{S}
\end{array}
\]
such that \( \tilde{S} \cong S \otimes_R \tilde{R} \) and \( \text{Tor}^R_i(S, \tilde{R}) = 0 \) for all \( i > 0 \). Let \( Y \in D_-(S) \). Then
\[
\text{id}_R(\text{Hom}_S(\tilde{S}, Y)) \leq \text{id}_R(Y).
\]

\textbf{Proof:} Replace \( \tilde{S} \) with \( S \otimes_R \tilde{R} \) if necessary to assume that \( \tilde{S} = S \otimes_R \tilde{R} \). Using [2, Proposition 2.1.10] we factor \( \beta \) as \( R \twoheadrightarrow \overline{R} \xrightarrow{\varepsilon \cong} \tilde{R} \) where \( \overline{R} \) is a commutative differential graded (DG) \( R \)-algebra such that \( \overline{R}_i \) is free over \( R \) for all \( i \), with \( \overline{R}_{<0} = 0 \), and \( \iota, \varepsilon \) are DG-algebra homomorphisms such that \( \varepsilon \) is a quasiisomorphism. See [2, 16] for relevant background on DG homological algebra.

Set \( \overline{S} = S \otimes_R \overline{R} \) which is a DG \( S \)-algebra such that \( \overline{S}_i \) is free over \( S \) for all \( i \), with \( \overline{S}_{<0} = 0 \). This gives the following commutative diagram of DG-algebra morphisms.
Claim: The DG-algebra morphisms $S \otimes R \epsilon$ and $S \otimes R \epsilon$ are quasiisomorphisms. Indeed since $\epsilon$ is a quasiisomorphism, $\text{Cone}(\epsilon)$ is exact. Because of the isomorphisms
\[
\text{Cone}(S \otimes R \epsilon) \cong (S \otimes R \bar{R}) \otimes \bar{R} \text{Cone}(\epsilon) \\
\cong S \otimes R \text{Cone}(\epsilon) \cong \text{Cone}(S \otimes R \epsilon)
\]
it suffices to show that $S \otimes R \text{Cone}(\epsilon)$ is exact. Observe that
\[
\text{Cone}(\epsilon) \cong \cdots \rightarrow \bar{R}_2 \rightarrow \bar{R}_1 \rightarrow \bar{R}_0 \rightarrow \bar{R} \rightarrow 0.
\]
Since each $\bar{R}_i$ is free, $\text{Tor}_{\geq 1}(S, \bar{R}_i) = 0$. Also, by assumption, we have that $\text{Tor}_{R}(S, \tilde{R}) = 0$. Since $\text{Cone}(\epsilon)$ is exact, $S \otimes R \text{Cone}(\epsilon)$ is exact as desired.

Without loss of generality assume that $\text{id}_R(Y) < \infty$. The properties of $S$ and $R$ listed above explain the first and last steps in the following sequence over $R$.
\[
\text{RHom}_S(\bar{S}, Y) \simeq \text{Hom}_S(\bar{S}, Y) \\
= \text{Hom}_S(S \otimes R \bar{R}, Y) \\
\cong \text{Hom}_R(\bar{R}, \text{Hom}_S(S, Y)) \\
\cong \text{Hom}_R(\bar{R}, Y) \\
\simeq \text{RHom}_R(\bar{R}, Y)
\]
The second step is by definition, the third step is Hom-tensor adjointness, and the fourth step is induced by Hom cancellation. Because $\text{id}_R(Y) < \infty$ and $\bar{R} \in \mathcal{D}_b(R)$, it follows that $\text{RHom}_S(\bar{S}, Y) \simeq \text{RHom}_R(\bar{R}, Y) \in \mathcal{D}_b(R)$.

The previous display gives the first isomorphism in $\mathcal{D}(\bar{R})$ in the following display for each $N \in \mathcal{D}_b(\bar{R})$. The second and third isomorphisms are by Hom-tensor adjointness and tensor cancellation respectively.
\[
\text{RHom}_{\bar{R}}(N, \text{RHom}_S(\bar{S}, Y)) \simeq \text{RHom}_{\bar{R}}(N, \text{RHom}_R(\bar{R}, Y)) \\
\simeq \text{RHom}_R(\bar{R} \otimes \bar{R}^! N, Y) \\
\simeq \text{RHom}_R(N, Y) \quad (A.1.1)
\]
Let $\text{RHom}_S(\bar{S}, Y) \xrightarrow{\sim} I$ be a semiinjective resolution over $\bar{S}$. Then
\[
\text{RHom}_{\bar{R}}(\bar{S}, \text{RHom}_S(\bar{S}, Y)) \simeq \text{Hom}_{\bar{R}}(\bar{S}, I).
\]
Let $W$ be an $\bar{R}$-module. Let $\bar{G} \xrightarrow{\sim} W$ be a semifree resolution over $\bar{R}$, and let $\tilde{G} \xrightarrow{\sim} W$ be a semifree resolution over $\bar{R}$ (and hence a quasiisomorphism over $\bar{R}$). Consider the following commutative diagram
\[
\begin{array}{ccc}
\text{Hom}_{\bar{R}}(\bar{S}, I) & \xrightarrow{\sim} & \text{Hom}_{\bar{R}}(\bar{S}, I) \\
\downarrow & & \downarrow \cong \\
I & & I
\end{array}
\]
where the vertical map is an isomorphism by Hom cancellation and the horizontal map is a quasiisomorphism because $\bar{S} \rightarrow \bar{S}$ is a quasiisomorphism and $I$ is semiinjective over $\bar{S}$. Hence by composition $\text{Hom}_{\bar{R}}(\bar{S}, I) \rightarrow I$ is a quasiisomorphism. By [10, Theorem 6.10(i)] we have a natural quasiisomorphism
\[
\text{Hom}_{\bar{R}}(\bar{G}, I) \xrightarrow{\sim} \text{Hom}_{\bar{R}}(\bar{G}, \text{Hom}_{\bar{R}}(\bar{S}, I)).
\]
This explains the second isomorphism in the next display. The first is by (A.3.1), and the third is induced by Hom-tensor adjointness and tensor cancellation.

\[
\text{RHom}_R(W, Y) \simeq \text{RHom}_R(W, \text{RHom}_S(\overline{S}, Y)) \\
\simeq \text{RHom}_R(W, \text{RHom}_R(\overline{S}, \text{RHom}_S(\overline{S}, Y))) \\
\simeq \text{RHom}_R(W, \text{RHom}_S(\overline{S}, Y))
\]

This justifies the equality in the next display.

\[
\inf(\text{RHom}_R(W, \text{RHom}_S(\overline{S}, Y))) = \inf(\text{RHom}_R(W, Y)) \geq \text{id}_R(Y).
\]

The inequality is by [3, Theorem 2.4.I]. From this and another application [3, Theorem 2.4.I] it follows that \(\text{id}_R(\text{RHom}_S(\overline{S}, Y)) \leq \text{id}_R(Y)\) as desired. \(\square\)

The next result is proved like the previous one. It is not needed for the results of this paper; however, see Remark 3.7.

**Lemma A.2.** Let \(R, S, \overline{R}, \overline{S}\) be commutative noetherian rings (not necessarily local) and consider the following commutative diagram of ring homomorphisms

\[
\begin{array}{ccc}
R & \longrightarrow & \overline{R} \\
\tau \downarrow & & \downarrow \overline{\tau} \\
S & \longrightarrow & \overline{S}
\end{array}
\]

such that \(S \cong \overline{R} \otimes_R \overline{S}\) and \(\text{Tor}^R_i(S, \overline{R}) = 0\) for all \(i > 0\). Let \(Y \in \mathcal{D}_+(S)\). Then

\[
\text{fd}_{\overline{R}}(\overline{S} \otimes_S Y) \leq \text{fd}_R(Y).
\]

The following result is a slight improvement on [24, Theorem 3.13]. Our proof is similar to that of op. cit., but we include it here for the sake of completeness.

**Proposition A.3.** Let \(R\) be a commutative noetherian ring (not necessarily local) with \(d = \dim(R) < \infty\). Let \(R'\) be a faithfully flat \(R\)-algebra. Then \(R\) is in the thick subcategory \(T\) of \(\mathcal{D}(R)\) generated by \(\text{Add}(R')\).

**Proof:** Claim 1: For all projective \(R\)-modules \(P\) and all \(n \geq 1\) the tensor product \(P \otimes_R (R')^{\otimes n}\) is in \(T\). In particular, for all \(n \geq 1\), we have \((R')^{\otimes n} \in T\).

Proof of Claim 1. We argue by induction on \(n\). For the base case \(n = 1\), note that \(P\) is a summand of \(R^{(B)}\) for some set \(B\). By definition we have \(R^{(B)} \otimes_R R' \cong (R')^{(B)} \in \text{Add}(R')\). Thus the summand \(P \otimes_R R'\) is also in \(\text{Add}(R') \subseteq T\).

Induction step: Assume that \(n \geq 1\) and that \(P \otimes_R (R')^{\otimes n} \in T\) for all \(P\). Fact 2.1 implies that \(\text{pd}_R(R') \leq d\). This provides a bounded projective resolution

\[
0 \rightarrow P_d \rightarrow \cdots \rightarrow P_0 \rightarrow R' \rightarrow 0
\]

where each projective \(R\)-module \(P_i\) is a summand of a free \(R\)-module \(R^{(B_i)}\) with basis \(B_i\). Apply \(- \otimes_R (P \otimes_R (R')^{\otimes n})\) to the resolution (A.3.1). As \((R')^{\otimes n}\) is flat, so is \(P \otimes_R (R')^{\otimes n}\). This yields an exact sequence

\[
0 \rightarrow P_d \otimes_R P \otimes_R (R')^{\otimes n} \rightarrow \cdots \rightarrow P_0 \otimes_R P \otimes (R')^{\otimes n} \rightarrow P \otimes_R (R')^{\otimes (n+1)} \rightarrow 0.
\]

Our induction hypothesis implies \(P_i \otimes_R P \otimes_R (R')^{\otimes n} \in T\) for all \(i\). As \(T\) is thick, the above exact sequence implies that \(P \otimes_R (R')^{\otimes (n+1)} \in T\). This establishes Claim 1.
Set $M = R'/R$, which is flat over $R$ since $R'$ is faithfully flat. Next set $I = \Sigma^{-1}M$ so there is a natural exact triangle in $\mathcal{D}(R)$

$$I \xrightarrow{\phi} R \rightarrow R' \rightarrow .$$  \hfill (A.3.2)

Claim 2: For all $m, n \geq 1$ we have $(R')^\otimes m \otimes_R I^\otimes n \in T$. In particular, $R' \otimes_R I^\otimes n \in T$ for all $n \geq 1$.

Proof of Claim 2. We argue by induction on $n$. For the base case $n = 1$, apply the functor $(R')^\otimes m \otimes_R -$ to the triangle \[A.3.2\] and use the flatness of $(R')^\otimes m$ to get the exact triangle

$$(R')^\otimes m \otimes_R I \rightarrow (R')^\otimes m \rightarrow (R')^\otimes (m+1) \rightarrow .$$

Since $(R')^\otimes m$ and $(R')^\otimes (m+1)$ are in $T$ by Claim 1, so is $(R')^\otimes m \otimes_R I$.

The induction step is similar to the base case. Assume that $n \geq 1$ and that $(R')^\otimes m \otimes_R I^\otimes n \in T$ for all $m \geq 1$. Apply $((R')^\otimes m \otimes_R I^\otimes n) \otimes_R -$ to the triangle \[A.3.2\] and use the flatness of $(R')^\otimes m \otimes_R M^\otimes n$ to get the exact triangle

$$(R')^\otimes m \otimes_R I^\otimes (n+1) \rightarrow (R')^\otimes m \otimes_R I^\otimes n \rightarrow (R')^\otimes (m+1) \otimes_R I^\otimes n \rightarrow .$$

Since $(R')^\otimes m \otimes_R I^\otimes n$ and $(R')^\otimes (m+1) \otimes_R I^\otimes n$ are in $T$, so is $(R')^\otimes m \otimes_R I^\otimes (n+1)$. This establishes Claim 2.

Recall the morphism $\phi$ from \[A.3.2\]. For each $n \in \mathbb{N}$, consider the natural morphism $I^\otimes n \xrightarrow{\phi^\otimes n} R^\otimes n \simeq R$ and the induced exact triangle

$$I^\otimes n \xrightarrow{\phi^\otimes n} R \rightarrow C(n) \rightarrow .$$  \hfill (A.3.3)

Claim 3: For all $m \geq 0$ and all $n \geq 1$ we have $I^\otimes m \otimes_R C(n) \in T$. In particular, $C(n) \in T$ for all $n \geq 1$.

Proof of Claim 3. We argue by induction on $n$. For the base case $n = 1$, compare the triangles \[A.3.2\] and \[A.3.3\] to conclude that $I^\otimes 0 \otimes_R C(1) \simeq C(1) \simeq R' \in T$. For $m \geq 1$ it follows that $I^\otimes m \otimes_R C(1) \simeq I^\otimes m \otimes_R R' \in T$ by Claim 2.

Induction step: Assume that $n \geq 1$ and that $I^\otimes m \otimes_R C(n) \in T$ for all $m \geq 0$. The morphism $\phi^\otimes (n+1)$ decomposes as the composition of the next morphisms

$$I^\otimes (n+1) \xrightarrow{\phi^\otimes (n+1)} R \otimes_R I \xrightarrow{\phi^\otimes n} I \xrightarrow{\phi^\otimes} R.$$  

Apply $- \otimes_R I$ to the triangle \[A.3.3\] to produce the next exact triangle

$$I^\otimes (n+1) \xrightarrow{\phi^\otimes (n+1)} R \otimes_R I \rightarrow C(n) \otimes_R I \rightarrow .$$

The Octahedral Axiom applied to the morphisms $\phi^\otimes n \otimes I$ and $\phi$ (and their composition $\phi^\otimes (n+1)$) yields the next exact triangle

$$C(n) \otimes_R I \rightarrow C(n+1) \rightarrow C(1) \rightarrow .$$

Apply $- \otimes_R I^\otimes m$ to this triangle to obtain the next one.

$$C(n) \otimes_R I^\otimes (m+1) \rightarrow C(n+1) \otimes_R I^\otimes m \rightarrow C(1) \otimes_R I^\otimes m \rightarrow .$$

Since $C(n) \otimes_R I^\otimes (m+1), C(1) \otimes_R I^\otimes m \in T$, we have $C(n+1) \otimes_R I^\otimes m \in T$. This establishes Claim 3.

Now we complete the proof. The module $M = R'/R$ is flat, hence so is $M^\otimes (d+1)$. Thus, we have $pd_R(M^\otimes (d+1)) \leq d$ and so $Ext_{R'}^d(M^\otimes (d+1), R) = 0$. It follows that

$$Ext_{R'}^0(I^\otimes (d+1), R) \cong Ext_{R'}^0(\Sigma^{-d-1}M^\otimes (d+1), R) \cong Ext_{R'}^d(M^\otimes (d+1), R) = 0.$$
It follows that the homotopy class of the morphism $\phi^{(d+1)}$ is in $\text{Ext}_R^0(I^{(d+1)}, R) = 0$, thus $\phi^{(d+1)}$ is nullhomotopic. It follows that the codomain $R$ is a retract of $C(d + 1)$. Claim 3 implies that $C(d + 1)$ is in $T$, which is closed under retracts. Therefore we have $R \in T$, as desired. \hfill $\square$

Our point for including Proposition A.3 is to obtain the next two results for use in Remark A.2.

**Proposition A.4.** Continue with the assumptions of Proposition A.3 and let $X \in \mathcal{D}(R)$ be such that $R\text{Hom}_R(R', X) \in \mathcal{D}_*(R)$, where $* \in \{+,-,b\}$. Then for all $Z \in T$ we have $R\text{Hom}_R(Z, X) \in \mathcal{D}_*(R)$.

**Proof:** By Remark A.2 we have $Z \in T_n$ for some $n \geq 1$. Argue by induction on $n$.

Base case: $n = 1$. In this case, $Z$ is a summand of $(R')^{(A)}$ for some $A$. The condition $R\text{Hom}_R(R', X) \in \mathcal{D}_*(R)$ implies that

$$R\text{Hom}_R((R')^{(A)}, X) \simeq R\text{Hom}_R(R', X)^A \in \mathcal{D}_*(R).$$

It follows that the summand $R\text{Hom}_R(Z, X)$ of $R\text{Hom}_R((R')^{(A)}, X)$ is also in $\mathcal{D}_*(R)$. Let $Z \in T_{n+1}$. Then $Z$ is a retract of an object $Y \in \mathcal{D}(R)$ such that there is an exact triangle $Y' \to Y \to Y'' \to$ in $\mathcal{D}(R)$ with $Y' \in T_1$ and $Y'' \in T_n$. Our base case and induction hypothesis imply that $R\text{Hom}_R(Y', X)$, $R\text{Hom}_R(Y'', X) \in \mathcal{D}_*(R)$. A long exact sequence argument shows that $R\text{Hom}_R(Y, X) \in \mathcal{D}_*(R)$. It follows that the retract $R\text{Hom}_R(Z, X)$ must also be in $\mathcal{D}_*(R)$. \hfill $\square$

**Corollary A.5.** Continue with the assumptions of Proposition A.3. Let $X \in \mathcal{D}(R)$ be such that $R\text{Hom}_R(R', X) \in \mathcal{D}_*(R)$, where $* \in \{+,-,b\}$. Then $X \in \mathcal{D}_*(R)$.

**Proof:** Proposition A.3 implies that $R \in T$, so we have $X \simeq R\text{Hom}_R(R, X) \in \mathcal{D}_*(R)$ by Proposition A.4. \hfill $\square$
