Abstract: A density functional theory plus Hubbard U method is used to investigate how the incorporation of Pu waste into Gd$_2$Zr$_2$O$_7$ pyrochlore influences its thermo-physical properties. It is found that immobilization of Pu at Gd-site of Gd$_2$Zr$_2$O$_7$ has minor effects on the mechanical and thermal properties, whereas substitution of Pu for Zr-site results in remarkable influences on the structural parameters, elastic moduli, elastic isotropy, Debye temperature and electronic structure. The discrepancy in thermo-physical properties between Gd$_{2-x}$Pu$_x$Zr$_2$O$_7$ and Gd$_2$Zr$_{2-x}$Pu$_x$O$_7$ may be a result of their different structural and electronic structures. This study provides a direct insight into the thermo-physical properties of Pu-containing Gd$_2$Zr$_2$O$_7$, which will be important for further investigation of nuclear waste immobilization by pyrochlores.

Keywords: DFT+U; Gd$_2$Zr$_2$O$_7$; nuclear waste; mechanical properties

1. Introduction

As the nuclear industry develops fast, ways to treat spent fuel and nuclear waste safely, such as plutonium and minor actinides (Np, Am, Cm), has become an important environmental conservation issue [1-3]. It is acceptable to store spent fuel and separated waste in stainless steel vessels in the short term, but in the long term it is hoped that this material will be transformed into more secure and manageable solids [1,4,5]. One method proposed for the treatment of plutonium is immobilization in zirconate pyrochlores, particularly Gd$_2$Zr$_2$O$_7$, which has high thermal stability, high chemical durability, and high radiation tolerance [6-9]. Besides, Gd is an effective neutron absorber [6].

Experimentally, Pu is often substituted by nonradioactive cerium (Ce), since they share the same crystallographic structure, and thermo-physical and chemical properties [10,11]. Zhao et al. synthesized (Gd$_{1-x}$Ce$_x$)$_2$Zr$_2$O$_7$ (0 ≤ x ≤ 0.6) solid solutions, indicating that Ce$^{3+}$ ions can be incorporated into the Gd$^{3+}$ sites. They proposed that the content of Pu$^{3+}$ immobilized at Gd-site was less than 40 mol% [12]. On the other hand, Gd$_2$(Zr$_{1-x}$Ce$_x$)$_2$O$_7$ (0 ≤ x ≤ 1.0) solid solutions have been synthesized by Reid et al. [13] and Patwe et al. [14]. They found that Ce can be immobilized at Zr sites entirely as Ce$^{4+}$, which leads to structural transformation from pyrochlore to fluorite phase, and its composition ranges from Gd$_2$Ce$_0$Zr$_{1.8}$O$_7$ to Gd$_2$Ce$_{1.7}$Zr$_{0.3}$O$_7$. Similar solution behavior...
and structural properties for Pu incorporation in Gd$_2$Zr$_2$O$_7$ have been obtained by first-principles calculations [15–17]. However, different electronic structures can be obtained for Ce and Pu immobilization at the Gd-site of Gd$_2$Zr$_2$O$_7$, i.e., the band gap increases and reduces when Ce and Pu substitutes for Gd site, respectively [15,18]. These differences mainly result from the different <Ce-O> and <Pu-O> interactions at band edges. The different electronic structure may result in varying mechanical properties. For Young’s modulus, which is described by $E \propto \frac{M_a}{r_0^4}$, with $M_a$ the Madelung constant and $r_0$ the interionic spacing [19], it is very sensitive to $r_0$. For ionic crystals, the $r_0$ is affected by bond interactions. According to these analyses, large discrepancies in electronic structures between Ce and Pu incorporation in Gd$_2$Zr$_2$O$_7$ may lead to different Young’s modulus. This indicates that for the mechanical properties of pyrochlores, Ce may not be a good substitute for Pu, despite the two having several similar thermo-physical properties. Thus far, there are no reports on the mechanical properties of Pu immobilization in Gd$_2$Zr$_2$O$_7$. It is necessary to explore how Pu doping influences the mechanical properties of Gd$_2$Zr$_2$O$_7$, because the knowledge of thermo-mechanical characteristics, for example, elastic moduli and Debye temperature is important for safe fuel disposal [20]. It provides new perspectives into the behavior of actinide incorporation in pyrochlores for their applications in harsh environments.

In this work, the structural, mechanical and electronic properties of Pu incorporation in Gd$_2$Zr$_2$O$_7$ are investigated by the density functional theory plus the Hubbard U method (DFT+U). The remaining part of the paper is structured as follows: Section 2 lists computational details; Section 3 contains our results and discussions, involving the structural stability, elastic constants with elastic moduli of Gd$_{2-y}$Pu$_y$Zr$_2$O$_7$ and Gd$_2$Zr$_{2-y}$Pu$_y$O$_7$, as well as the ductility, elastic anisotropy, Debye temperature and electronic structures of Pu-doped Gd$_2$Zr$_2$O$_7$. In Section 4, we summarize our conclusions.

2. Computational Details

The density functional theory method within the Vienna Ab-initio Simulation Package (VASP) [21,22] are employed in all the computations. The Hubbard U correction [23] is considered to take into account the strong correlation interaction between 5f electrons of Pu and the effective U values are taken to be 4 eV. The projector augment wave (PAW) method [24] is used to describe the interaction between electrons and ions. As for the exchange-correlation functional, a number of generalized gradient approximation (GGA) functionals have been reported in the literature [25–27] and the functional parametrized by Perdew, Burke and Ernzerhof [28] is employed in this work. In the calculations, a $2 \times 2 \times 2$ k-point sampling in reciprocal space is employed, with a cutoff energy of 600 eV for the plane wave basis sets. Figure 1 illustrates the schematic view of geometrical structure for the considered compounds, i.e., Gd$_{2-y}$Pu$_y$Zr$_2$O$_7$ and Gd$_2$Zr$_{2-y}$Pu$_y$O$_7$ ($y = 0, 0.5, 1.0, 1.5, 2.0$). The special quasi-random structure method is used to build the structural models for Pu immobilization at Gd-site and Zr-site [29–32].
3. Results and Discussion

3.1. Structural Stability of Pu Incorporation into Gd$_2$Zr$_2$O$_7$

As Pu substitutes for Gd$^{3+}$ and Zr$^{4+}$ in Gd$_2$Zr$_2$O$_7$, the corresponding valence states for Pu are Pu$^{3+}$ and Pu$^{4+}$, respectively. Because in both PuO$_2$ and Pu$_2$O$_3$ the Pu 5f electrons are strongly correlated, Hubbard $U$ correction is thus necessary. In the revised manuscript, we present the density of state distribution for both PuO$_2$ and Pu$_2$O$_3$ at $U_{\text{eff}} = 0$ eV and $U_{\text{eff}} = 4$ eV in Figure 2. It is shown that without Hubbard $U$ correction, i.e., at $U_{\text{eff}} = 0$ eV, the Pu 5f electrons are itinerant and delocalized over the Fermi lever, resulting in metallic states. At $U_{\text{eff}} = 4$ eV, the Pu 5f electrons are localized and the system becomes insulating, which is consistent with the experimental finding [32]. The calculated lattice constant of 5.46 Å for PuO$_2$ and 11.18 Å for Pu$_2$O$_3$ obtained at $U_{\text{eff}} = 4$ eV are comparable to the experimental values of 5.39 Å [33] and 10.98 Å [34], respectively. The calculated band gap for Pu$_2$O$_3$ at $U_{\text{eff}} = 4$ eV is 1.757 eV, which corresponds to the experimental value of 2 eV [35]. Thus, we use
$U_{\text{eff}} = 4 \text{ eV}$ in our subsequent calculations for Pu immobilization in Gd$_2$Zr$_2$O$_7$. On the other hand, the 4 eV for $U_{\text{eff}}$ is also consistent with the value of 4–5 eV that are reported in the literature [36,37].

Figure 2. Density of state distribution for PuO$_2$ at (a) $U_{\text{eff}} = 0 \text{ eV}$ and (b) 4 eV and for Pu$_2$O$_3$ at (c) $U_{\text{eff}} = 0 \text{ eV}$ and (d) 4 eV obtained by GGA+U.

A structural optimization is first performed for both Gd$_{2}$–yPu$_{y}$Zr$_2$O$_7$ and Gd$_2$Zr$_{2}$–yPu$_{y}$O$_7$. The calculated lattice constants, oxygen positional parameter $x_{O48f}$ and bond distances for Gd$_{2}$–yPu$_{y}$Zr$_2$O$_7$ and Gd$_2$Zr$_{2}$–yPu$_{y}$O$_7$ are listed in Tables 1 and 2, respectively. The changes of lattice constant and $x_{O48f}$ for Gd$_{2}$–yPu$_{y}$Zr$_2$O$_7$ and Gd$_2$Zr$_{2}$–yPu$_{y}$O$_7$ with Pu concentrations are shown in Figure 3. The calculated lattice constant of 10.666 Å for Gd$_2$Zr$_2$O$_7$ is slightly larger than the experimental value of 10.54 Å [38], while consistent with other calculations of 10.66 Å [18]. The calculated a$_0$ of 10.802 Å for Pu$_2$Zr$_2$O$_7$ is comparable with the experimental value of 10.70 Å [39]. As the Pu content increases, the lattice constant gradually increases for both Gd$_{2}$–yPu$_{y}$Zr$_2$O$_7$ and Gd$_2$Zr$_{2}$–yPu$_{y}$O$_7$, and it changes more significantly for Gd$_2$Zr$_{2}$–yPu$_{y}$Zr$_2$O$_7$ than that for Gd$_{2}$–yPu$_{y}$Zr$_2$O$_7$. This is caused by the fact that the effective ionic radius of 1.053 Å [40] for Gd$^{3+}$ is in good agreement with the value of $\sim$1.1 Å [40] for Pu$^{3+}$, but the effective ionic radius of 0.72 Å [40] for Zr$^{4+}$ is much smaller than the value of 0.96 Å [40] for Pu$^{4+}$. With regard to oxygen positional parameter $x_{O48f}$, the calculated value of 0.339 for Gd$_2$Zr$_2$O$_7$ is smaller than the experimental value of 0.345 [41], and is comparable to the calculated value of 0.339 reported by Wang et al. [18]. For Gd$_{2}$–yPu$_{y}$Zr$_2$O$_7$, the $x_{O48f}$ changes slightly as the Pu content increases, which indicates that the Gd$_{2}$–yPu$_{y}$Zr$_2$O$_7$ remains the pyrochlore structure. Wang et al. [18] has observed similar phenomenon for Gd$_{2}$–yCe$_{y}$Zr$_2$O$_7$. For Gd$_2$Zr$_{2}$–yPu$_{y}$O$_7$, we find that the $x_{O48f}$ increases a lot, varying from 0.339 to 0.350, suggesting that the Gd$_2$Zr$_{2}$–yPu$_{y}$O$_7$ tends to be a defect fluorite structure as the Pu content increases [15]. Comparing the lattice constant and oxygen positional parameter for Gd$_{2}$–yPu$_{y}$Zr$_2$O$_7$ and Gd$_2$Zr$_{2}$–yPu$_{y}$O$_7$, we find that the formation of Gd$_2$Zr$_2$O$_7$–Pu$_2$Zr$_2$O$_7$ solid solution is more preferable than that of Gd$_2$Zr$_2$O$_7$ and Gd$_2$Pu$_2$O$_7$. As for bond distances, the calculated <Gd-O$_{48f}$> distance of 2.553 Å in Gd$_2$Zr$_2$O$_7$ is a little larger than the experimental value of 2.483 Å [38],
and is comparable to other calculated value of 2.548 Å [18]. Meanwhile, the calculated value of 2.109 Å for <Zr-O48f> distance is consistent with the experimental value [38] and other calculated value [18] of 2.110 Å. For Gd2−yPu7Zr2O7, the <Gd-O48f> and <Pu-O48f> distances increase slightly and the <Gd-O8b> and <Pu-O8b> distances decrease slightly as the Pu content increases. Comparing the <Gd-O> and <Pu-O> bonds, we find that the <Pu-O48f> and <Pu-O8b> distances are slightly larger than <Gd-O48f> and <Gd-O8b> distances, respectively, i.e., Pu substitution for Gd-site leads to small increase in the bonding distance. For Gd2Zr2−yPu7O7, the situation is different. The <Pu-O48f> bond is about 0.12–0.19 Å larger than the <Zr-O48f> bond. Simultaneously, the <Gd-O8b> bond increases a little as the Pu content increases. Consequently, there is a remarkable increase in the lattice constant of Gd2−yPu7Zr2O7.

### 3.2. Elastic Constants and Elastic Moduli of Gd2−yPu7Zr2O7 and Gd2Zr2−yPu7O7

Elastic constants are response functions to the external forces and are very important in the materials’ properties [42]. Table 3 lists the calculated elastic constants along with available experimental and theoretical values. For Gd2Zr2O7, the calculated C_{11}, C_{12} and C_{44} are 285.1, 102.5 and 82.1 GPa, respectively, showing good agreement with other calculations [43]. For Pu2Zr2O7, the calculated...
Elastic constants are response functions to the external forces and are very important in the investigation of the mechanical properties of materials. Generally speaking, as the Pu content increases, there are more significant changes on Zr-site than Gd-site, meaning that Pu immobilization at Zr-site leads to remarkable variations in the mechanical properties. Table 3 presents the changes of elastic constants with Pu content for both Gd$_{2}$−$y$Pu$_{y}$Zr$_{2}$O$_{7}$ and Gd$_{2}$Zr$_{2}$−$y$Pu$_{y}$O$_{7}$ (0 ≤ $y$ ≤ 2).

![Figure 4](image-url)  
Figure 4. Variation of elastic constants (C$_{11}$, C$_{12}$ and C$_{44}$) for (a) Gd$_{2}$−$y$Pu$_{y}$Zr$_{2}$O$_{7}$ and (b) Gd$_{2}$Zr$_{2}$−$y$Pu$_{y}$O$_{7}$ (0 ≤ $y$ ≤ 2) with Pu content.
From the calculated elastic constants, the elastic moduli, including the bulk modulus ($B$), shear modulus ($G$) and Young’s modulus ($E$), can be deduced [48–51], i.e.,

$$B = B^V = B^R = \frac{C_{11} + 2C_{12}}{3},$$

$$G^V = \frac{C_{11} - C_{12} + 3C_{44}}{5},$$

$$G^R = \frac{5(C_{11} - C_{12})C_{44}}{4C_{44} + 3(C_{11} - C_{12})},$$

$$G = G^{VRH} = \frac{G^V + G^R}{2},$$

$$E = \frac{9BG}{3B + G}.$$

Here, the Voigt and Reuss evaluations for $B$ and $G$ are represented by $V$ and $R$, respectively. Table 3 lists the calculated $B$, $G$, $E$, and others’ theoretical and experimental values for both Gd$_{2-y}$Pu$_y$Zr$_2$O$_7$ and Gd$_2$Zr$_2$O$_7$. For Gd$_2$Zr$_2$O$_7$, the calculated $B = 163.4$ GPa, $G = 85.7$ GPa, $E = 218.8$ GPa are comparable with experimental [20,45,46] and other calculated [43] results. Figure 5 shows the variation of elastic moduli for both Gd$_{2-y}$Pu$_y$Zr$_2$O$_7$ and Gd$_2$Zr$_2$O$_7$. For Gd$_{2-y}$Pu$_y$Zr$_2$O$_7$, the elastic moduli change very slightly as the Pu content increases. When Pu is immobilized at Zr-site, there are remarkable changes. The bulk modulus first decreases, reaching a minimum of 134.3 GPa at $y = 1.0$, then rises up to 142.3 GPa at $y = 1.5$ and finally decreases to 136.9 GPa at $y = 2.0$. The shear modulus decreases to 58.9 GPa at $y = 1.0$ and increases slightly to 63.6 GPa at $y = 2.0$. The Young’s modulus decreases sharply from 218.8 GPa to 154.2 GPa as the $y$ varies from 0 to 1.0, but increases again to 165.7 GPa at $y = 1.5$, finally changing slightly. The <Zr-O> bonds determine the total stiffness of A$_2$Zr$_2$O$_7$ pyrochlore, because the corner-sharing ZrO$_6$ octahedra constitutes its backbone, and the A$_{2+}$ fills the interstices [19,52]. Therefore, the substitution of Zr$_{2+}$ by Pu$_{4+}$ causes the change of <Zr-O> bonds to <Pu-O> bonds and influences the Young’s modulus, especially for these ionic bonds [19,52]. The Young’s modulus $E$ is described by $E \propto \frac{M_a}{r_0}$ for ionic bonds, in which $M_a$ represents the Madelung constant and $r_0$ represents the interionic distance [19]. The <Zr-O> bonds in Gd$_2$Zr$_2$O$_7$ are affected little by Pu substitution for Gd-site, leading to slight effects on the Young’s modulus. For Gd$_{2-y}$Pu$_y$O$_7$, the <Zr-O$_{48f}$> bond length of 2.11 Å is smaller than the value of 2.26 Å for <Pu-O$_{48f}$>, resulting in remarkable effects on the Young’s modulus. The bulk modulus, shear modulus and Young’s modulus for Nd doping of Gd$_2$Zr$_2$O$_7$ have been calculated by Zhao et al. [47], who also reported that Nd immobilization at Zr-site has more remarkable influences on the elastic moduli than that at Gd-site.

![Figure 5](image.png)

**Figure 5.** Variation of elastic moduli for (a) Gd$_{2-y}$Pu$_y$Zr$_2$O$_7$ and (b) Gd$_2$Zr$_2$O$_7$ ($0 \leq y \leq 2$) as a function of Pu content. B: bulk modulus; G: shear modulus; E: Young’s modulus.
For each ion in Gd$_{2-y}$Pu$_y$Zr$_2$O$_7$ and Gd$_2$Zr$_{2-y}$Pu$_y$O$_7$, we analyze the Bader charge to explore the origin of the discrepancy in the elastic moduli between Gd$_{2-y}$Pu$_y$Zr$_2$O$_7$ and Gd$_2$Zr$_{2-y}$Pu$_y$O$_7$. The Bader charge values are listed in Table 4. As Pu is immobilized at Gd-site and Zr-site, the average Bader charge for Pu are 2.10 |e| and 2.33 |e|, respectively, corresponding to the nominal +3 |e| and +4 |e| in oversimplified classical model [2]. For Gd$_{2-y}$Pu$_y$Zr$_2$O$_7$, the Bader charge for Gd and Pu ions are similar to each other, i.e., 2.15 and 2.10 |e|, respectively. Considering that the <Pu-O> and <Gd-O> bonding distance for Gd$_{2-y}$Pu$_y$Zr$_2$O$_7$ and Gd$_2$Zr$_{2-y}$Pu$_y$O$_7$ are similar to each other, i.e., 2.15 and 2.10 |e|, respectively. Wang et al. [18] calculated the Bader charge of Gd$_{2-y}$Ce$_y$Zr$_2$O$_7$ and reported very similar results. Additionally, the bonding distance for <Gd-O$_{48f}$> and <Gd-O$_{8b}$> are determined to be 2.57 Å and 2.30 Å, which are comparable to the values of 2.60 Å for <Pu-O$_{48f}$> and 2.56 Å for <Pu-O$_{8b}$>, respectively. Obviously, the <Gd-O> and <Pu-O> bonding interaction are very similar to each other, which explains why the mechanical properties of Gd$_2$Zr$_2$O$_7$ are affected slightly by Pu immobilization at Gd-site. For Gd$_2$Zr$_{2-y}$Pu$_y$O$_7$, the situation is much different. The average Bader charge are 2.33 |e| for Pu ions and 2.26 |e| for Zr ions. Considering that the <Pu-O$_{48f}$> distance of 2.26 Å is larger than the <Zr-O$_{48f}$> distance of 2.11 Å and the ionic radius of 0.96 Å for Pu ions is larger than that of 0.72 Å for Zr ions [40], it is suggested that the <Zr-O> bonds exhibit weaker ionicity than <Pu-O> bonds in Gd$_2$Zr$_{2-y}$Pu$_y$O$_7$. Because of the brittleness of the ionic bonds, the immobilization of Pu at Zr sites will thus increase the ionicity and decrease the elastic moduli.

Table 4. Bader charge (|e|) for each ion in Gd$_{2-y}$Pu$_y$Zr$_2$O$_7$ and Gd$_2$Zr$_{2-y}$Pu$_y$O$_7$ (y = 0, 0.5, 1.0, 1.5, 2.0).

3.3. Ductility, Elastic Anisotropy, Debye Temperature and Electronic Structures of Pu-Doped Gd$_2$Zr$_2$O$_7$

Pugh’s indicator ($\frac{E}{H}$) is used to reflect the ductility of materials. If $\frac{E}{H} > 1.75$, the material shows ductility; or, it is brittle [54]. Table 5 presents the calculated Pugh’s indicators. For Gd$_2$Zr$_2$O$_7$, our value of 1.907 is comparable with the experimental values of 1.913 [45,46], 1.891 [20] and other calculated value of 2.004 [53]. For both Gd$_{2-y}$Pu$_y$Zr$_2$O$_7$ and Gd$_2$Zr$_{2-y}$Pu$_y$O$_7$, our calculations show that the Pugh’s indicators are all larger than 1.75, implying that all the considered composites are ductile. Poisson’s indicator ($\nu$) can be employed to evaluate the relative ductility of materials. When $\nu$ is around 0.1, the material shows brittle covalent properties. When $\nu$ is bigger than 0.25, it exhibits ductile ionic properties [55]. Table 5 lists the calculated, experimental and others’ calculated Poisson’s ratio for both Gd$_{2-y}$Pu$_y$Zr$_2$O$_7$ and Gd$_2$Zr$_{2-y}$Pu$_y$O$_7$. For Gd$_2$Zr$_2$O$_7$, the calculated Poisson’s ratio of 0.277 could be comparable to the experimental values of 0.276 [45,46], 0.274 [20] and other calculated results of 0.286 [53] and 0.273 [43]. The Poisson’s ratios for Gd$_{2-y}$Pu$_y$Zr$_2$O$_7$ and Gd$_2$Zr$_{2-y}$Pu$_y$O$_7$ are all larger than 0.25, as presented in Table 5, i.e., the Pu-substituted Gd$_2$Zr$_2$O$_7$ exhibit good ductility.
Elastic anisotropy is an important parameter for phase transformations, dislocation dynamics and geophysical applications [56]. Ranganathan and co-workers [57,58] proposed the universal elastic anisotropic index to indicate the elastic anisotropy of cubic crystals. The index \( A^U \) is defined as:

\[
A^U = \frac{\theta^2}{\nu^2} = 0.5 \left( \frac{\theta}{\nu} \right)^2 - 6
\]

where \( \theta \) and \( \nu \) are the Debye temperature and Poisson’s ratio, respectively. This index is useful for comparing the elastic anisotropy of different materials and for predicting phase transformations.

The thermal properties of materials can be analyzed by the Debye temperature [4]. Table 5 lists the calculated and available experimental Debye temperature. The calculated \( \theta_D \) value of 580.2 K for Gd\(_2\)Zr\(_2\)O\(_7\) is larger than the experimental result of 513.3 K [20], but shows better agreement with experimental value than another calculated value of 612.9 K [53]. As the Pu concentration increases, the \( \theta_D \) value decreases for both Gd\(_{2-y}\)Pu\(_y\)Zr\(_2\)O\(_7\) and Gd\(_2\)Zr\(_{2-y}\)Pu\(_y\)O\(_7\). In particular, the \( \theta_D \) values for Gd\(_2\)Zr\(_{2-y}\)Pu\(_y\)O\(_7\) are smaller than those for Gd\(_{2-y}\)Pu\(_y\)Zr\(_2\)O\(_7\). These results imply that the Gd\(_2\)Zr\(_{2-y}\)Pu\(_y\)O\(_7\) compositions have a lower melting point and weaker interatomic binding force than the Gd\(_2\)Zr\(_2\)Pu\(_y\)O\(_7\) compositions. Zhao et al. [59] calculated the Debye temperature for Th immobilization at Gd-site and Zr-site of Gd\(_2\)Zr\(_2\)O\(_7\) and observed similar phenomena, i.e., the Th-substituted Gd\(_2\)Zr\(_2\)O\(_7\) have a lower Debye temperature and especially smaller Debye temperature can be obtained by the Th immobilization at Zr-site than that at Gd-site.

The total and projected density of state (DOS) distributions for Gd\(_{2-y}\)Pu\(_y\)Zr\(_2\)O\(_7\) and Gd\(_2\)Zr\(_{2-y}\)Pu\(_y\)O\(_7\) are illustrated in Figures 6 and 7, respectively. Tables 1 and 2 list the band gap values. It is shown that all the compositions have large band gap values. For Gd\(_2\)Zr\(_2\)O\(_7\), the calculated band gap is 2.86 eV. For Pu incorporation into Gd-site, the band gap values of 2.27–2.37 eV are smaller than that of Gd\(_2\)Zr\(_2\)O\(_7\) and nearly independent of the Pu content. For Gd\(_2\)Zr\(_{2-y}\)Pu\(_y\)O\(_7\), the changes in the band gap are more significant, ranging from 2.33 to 1.68 eV. It is indicated that Pu immobilization at Gd-site and Zr-site has different influences on the electronic structure of Gd\(_2\)Zr\(_2\)O\(_7\). The same conclusion can be drawn from the density of state distribution. For Gd\(_{2-y}\)Pu\(_y\)Zr\(_2\)O\(_7\), O 2p orbital dominates and hybridizes with very few Gd 5d, Pu 5f and Zr 4d orbitals in the energy range of \( -5-1 \) eV, and the Pu 5f orbitals hybridize with the O 2p orbitals at the bottom of valence band. For Gd\(_2\)Zr\(_{2-y}\)Pu\(_y\)O\(_7\), the O 2p orbital dominates and hybridizes with Pu 5f orbitals and very few Zr 4d and Gd 5d orbitals at the valence band. Obviously, in Gd\(_2\)Zr\(_2\)O\(_7\), different electronic structures can be obtained from the immobilization of Pu at Gd and Zr sites. These different electronic structures may result in discrepancies in the thermo-physical properties of Gd\(_{2-y}\)Pu\(_y\)Zr\(_2\)O\(_7\) and Gd\(_2\)Zr\(_{2-y}\)Pu\(_y\)O\(_7\).
Our calculations suggest that the Gd$_2$Zr$_2$O$_7$ is a promising material for immobilizing nuclear waste.

The mechanical and electronic properties of Pu-containing Gd$_2$Zr$_2$O$_7$ are studied by a DFT+U method. For Gd$_{2-y}$Pu$_y$Zr$_2$O$_7$ and Gd$_2$Zr$_{2-y}$Pu$_y$O$_7$, the elastic stability criteria are satisfied for all the calculated elastic constants, i.e., all the compounds are mechanically stable. As Pu immobilizes at Gd-site in Gd$_2$Zr$_2$O$_7$, because the bonding distance and covalency of \(<\text{Gd-O}>\) and \(<\text{Pu-O}>\) bonds are comparable to each other, the elastic constants, elastic moduli, elastic isotropy and Debye temperature of Gd$_2$Zr$_2$O$_7$ are all affected a little. As for Gd$_2$Zr$_{2-y}$Pu$_y$O$_7$, the elastic constants and elastic moduli change remarkably as compared with Gd$_2$Zr$_2$O$_7$. The substitution of Pu for Zr sites increases the ionicity and decreases the elastic moduli, because the \(<\text{Zr-O}>\) bonds exhibit weaker ionicity than \(<\text{Pu-O}>\) bonds. In addition, the Debye temperature is decreased and the band gap is greatly reduced.

Our calculations suggest that the Gd$_2$Zr$_2$O$_7$ is a promising material for immobilizing nuclear waste.

4. Conclusions

The mechanical and electronic properties of Pu-containing Gd$_2$Zr$_2$O$_7$ are studied by a DFT+U method. For Gd$_{2-y}$Pu$_y$Zr$_2$O$_7$ and Gd$_2$Zr$_{2-y}$Pu$_y$O$_7$, the elastic stability criteria are satisfied for all the calculated elastic constants, i.e., all the compounds are mechanically stable. As Pu immobilizes at Gd-site in Gd$_2$Zr$_2$O$_7$, because the bonding distance and covalency of \(<\text{Gd-O}>\) and \(<\text{Pu-O}>\) bonds are comparable to each other, the elastic constants, elastic moduli, elastic isotropy and Debye temperature of Gd$_2$Zr$_2$O$_7$ are all affected a little. As for Gd$_2$Zr$_{2-y}$Pu$_y$O$_7$, the elastic constants and elastic moduli change remarkably as compared with Gd$_2$Zr$_2$O$_7$. The substitution of Pu for Zr sites increases the ionicity and decreases the elastic moduli, because the \(<\text{Zr-O}>\) bonds exhibit weaker ionicity than \(<\text{Pu-O}>\) bonds. In addition, the Debye temperature is decreased and the band gap is greatly reduced.

Our calculations suggest that the Gd$_2$Zr$_2$O$_7$ is a promising material for immobilizing nuclear waste.
