Abstract: We examined effects of a major lipotrope, myo-inositol, on the expression of primary glycolytic (glucokinase and phosphofructokinase) and fructolytic enzyme (ketohexokinase [KHK] and aldolase B) genes in the livers of rats fed a control diet, high-sucrose diet, or high-sucrose diet supplemented with 0.5% myo-inositol for 14 d. Supplementation with myo-inositol decreased the hepatic expression of fructolytic enzyme genes, but not that of glycolytic enzyme genes, and the levels of triglycerides, fatty acid synthase, and KHK proteins in high-sucrose diet-induced fatty liver. The study results suggest that myo-inositol represses primary fructolysis, but not glycolysis, in high-sucrose diet-induced fatty liver.

Key words: KHK, liver, myo-inositol, rats, sucrose

1 Introduction
Sucrose is digested by sucrase and metabolized into monosaccharides, glucose and fructose, in the small intestine. The two monosaccharides, after absorption from the small intestine, reach the liver via the portal vein. In the liver, glucose can be partially converted into fatty acids and stored as triglycerides after it is metabolized by two highly regulated enzymes in glycolysis, glucokinase (GK) and phosphofructokinase (PFK). In contrast, fructose is metabolized by two key fructolytic enzymes, ketohexokinase (KHK) and aldolase B (ALDOB) and is more rapidly utilized than glucose for de novo lipogenesis because fructose bypasses the glycolytic rate-limiting step, PFK. Thus, excessive intake of sucrose promotes not only the prevalence and/or development of fatty liver, but also that of other metabolic diseases, such as insulin resistance and type 2 diabetes⁷. Therefore, repression of sucrose-induced fatty liver is a key strategy for the prevention of these metabolic diseases.

Myo-inositol, the most common form of inositol of the nine distinct stereoisomers, is well-known to be a major lipotrope. It is found in the free form in fruits such as kiwi or citrus⁶. Several animal studies have reported that dietary supplementation with myo-inositol effectively reduces the accumulation of triglycerides, expression of genes of fatty acid synthesis enzymes, and activity of fatty acid synthesis enzymes in rats with high-sucrose diet-induced fatty liver³⁷. In addition, we have shown that dietary supplementation with myo-inositol decreases not only the accumulation of triglycerides and expression of fatty acid synthesis enzyme genes and protein, but also the expression of fructolysis enzyme genes in the fatty liver of rats fed a high-fructose diet⁸. However, it remains unclear whether the intake of myo-inositol affects the expression of genes related to either glycolysis or fructolysis, or both, in high-sucrose-induced fatty liver.

In this study, we examined the effects of dietary supplementation with myo-inositol on the hepatic expression of primary glycolytic and fructolytic enzyme genes in the livers of rats fed a high-sucrose diet.

2 Experimental
2.1 Animals and diets
Four-week-old Wistar male rats (SLC, Shizuoka, Japan) were housed individually in metal cages in a temperature-controlled room (22°C ± 2°C) under a 12-h light/dark cycle.

lights on from 07:00-19:00 and fed a laboratory chow diet (MF; Oriental Yeast, Tokyo, Japan). After an acclimation period of 5 d, the rats were assigned to one of the following 3 diet groups (n = 6) for 14 d: control diet, high-sucrose diet, or high-sucrose diet supplemented with 0.5% myo-inositol. The purity of myo-inositol (Nacalai Tesque, Kyoto, Japan) was ≥ 99.0%. Details of diet composition are presented in Table 1. The animals had free access to food and water. At the end of the feeding period, the rats were euthanized by decapitation under isoflurane anesthesia after a 4-h fasting period. Liver tissues were harvested and stored in liquid nitrogen. All animal care and experimental procedures were approved by the Gifu University Animal Care and Usage Committee.

2.2 Serum lipid assay
Blood samples were collected after decapitation and centrifuged at 1,710 × g for 15 min at 4°C. Serum samples were collected and stored at −30°C until use. The concentrations of glucose, insulin, triglycerides, total cholesterol, and phospholipids in the samples were measured using commercial kits (Glucose CII-test Wako, LBIS Insulin-Rat U-E type, Triglyceride E-test Wako, Cholesterol E-test Wako, and Phospholipid C-test Wako, respectively; FUJIFILM Wako Pure Chemical Corporation, Osaka, Japan).

2.3 Hepatic lipid assay
Total lipids from the rat liver tissues were extracted using the method described by Bligh and Dyer9 with some modifications. Briefly, frozen liver tissue was homogenized and mixed with chloroform, methanol, and 0.1 M KCl in a ratio of 1:1:1 (v/v/v). The homogenates were centrifuged at 800 × g for 10 min at room temperature and the lower organic phases were collected and dried as lipid extracts. The lipid extract samples were dissolved in isopropanol, and the amounts of triglycerides and cholesterol in the samples were measured using commercial kits (Triglyceride E-test Wako and Cholesterol E-test Wako, respectively; FUJIFILM Wako Pure Chemical Corporation).

2.4 Real-time quantitative PCR
Total RNA was extracted from the frozen liver tissues using a RNeasy Mini kit (Qiagen, Tokyo, Japan) according to the manufacturer’s instructions and stored at −80°C before use. Total RNA was converted to cDNA using a ReverTra Ace qPCR RT kit (Toyo-bo, Osaka, Japan) according to the manufacturer’s instructions. The cDNA samples were stored at −80°C until they were ready for use. Real-time quantitative PCR was performed in a final volume of 20 μL containing SYBR Green (TB Green Premix Ex Taq; Takara, Shiga, Japan), 0.2 μM of each primer, Rox reference dye, and 20 ng of cDNA, using a real-time PCR system (Step One Plus; Applied Biosystems Japan, Tokyo, Japan). The primers used are listed in Table 2. Expression of each tested gene was normalized to the housekeeping gene 36B4 using the 2−ΔΔCT method10.

2.5 Immunoblot
The frozen liver tissues were homogenized in ice-cold RIPA buffer (FUJIFILM Wako Pure Chemical Corporation) containing protease inhibitors (Complete Mini; Sigma-Aldrich Japan, Tokyo, Japan). The homogenates were centrifuged at 16,100 × g for 30 min at 4°C and the lysate samples collected. Protein concentrations in the samples were de-

Values are expressed as mean ± SEM. The significance of differences between the groups was determined using Tukey’s test, based on one-way analysis of variance. *P* < 0.05 indicated statistical significance.

3 Results and Discussion

In this study, serum levels of glucose, insulin, and total cholesterol did not significantly differ between rats fed a control diet, high-sucrose diet, and high-sucrose diet supplemented with myo-inositol. Serum triglyceride levels were significantly higher in the high-sucrose groups.

determined using the BCA assay (BCA protein assay kit; Takara) and stored at −80°C until ready for use. The lysate samples containing an equal amount of protein were separated by 5% and 12.5% SDS-PAGE and then transferred onto PVDF membranes (0.2-μm, hydrophobic, Clear Trans SP PVDF Membrane; FUJIFILM Wako Pure Chemical Corporation). After transfer, the membranes were washed in PBS with 0.1% Tween 20 (PBS-T) and blocked in 3-5% skimmed milk in PBS-T for 1 h at room temperature. Thereafter, the membranes were incubated overnight at 4°C with the following primary antibodies: anti-fatty acid synthase (FAS) antibody (Gene Tex, CA, USA), anti-KHK (Gene Tex) antibody, and anti-α-tubulin antibody (Cell Signaling Technology Japan, Tokyo, Japan). Subsequently, the membranes were washed in PBS-T and incubated for 1 h at 4°C with the secondary antibody conjugated to HRP (Cell Signaling Technology Japan). After washing with PBS-T, the signals were detected by ECL (ImmunoStar LD; FUJIFILM Wako Pure Chemical Corporation) according to the manufacturer’s instructions and using an imaging system (LAS3000; FUJIFILM, Tokyo, Japan). The expression of each protein was normalized using a loading control, α-tubulin.

Effects of dietary supplementation with myo-inositol on hepatic expression of glycolytic and fructolytic enzyme genes in rats fed a high-sucrose diet. Hepatic mRNA levels of (A) glycolytic and (B) fructolytic enzyme genes were analyzed by real-time quantitative PCR. The mRNA levels of the tested genes were normalized to that of 36B4. Values are expressed as mean ± SEM (n = 6). Values not sharing a common superscript are significantly different (p < 0.05, Tukey’s test based on one-way analysis of variance). Control, control diet; Sucrose, high-sucrose diet; Sucrose+myo-inositol, high-sucrose diet plus 0.5% myo-inositol.

Fig. 1

Effects of dietary supplementation with myo-inositol on hepatic expression of FAS and KHK proteins. (A) Protein expression was measured in liver tissue lysates by immunoblot. Quantitative analysis of (B) FAS and (C) KHK protein based on densitometry of immunoblot. The protein levels of the tested protein were normalized to that of α-tubulin. Values are expressed as means ± SEM (n = 5). Values not sharing a common superscript are significantly different (p < 0.05, Tukey’s test based on one-way analysis of variance). Control, control diet; Sucrose, high-sucrose diet; Sucrose+myo-inositol, high-sucrose diet plus 0.5% myo-inositol.

Fig. 2

very-low-density lipoprotein from the liver, but not the enhanced secretion of chylomicron from the small intestine. Thus, this may explain why myo-inositol did not decrease serum triglyceride levels.

We showed that dietary supplementation with myo-inositol significantly lowered the expression of the KHK gene and KHK protein (p < 0.05) and tended to lower the expression of ALDOB, p = 0.068, (Figs. 1B and 2C). To the best of our knowledge, this is the first study to report that myo-inositol supplementation remarkably decreases the expression of the KHK gene and KHK protein as well as the accumulation of triglycerides and expression of the FAS protein in high-sucrose diet-induced fatty liver in rats. Our previous study reported that dietary supplementation with myo-inositol reduced the expression of fructolytic and fatty acid synthesis enzyme genes and accumulation of triglycerides in the fatty livers of rats fed a high-fructose diet. Therefore, it is most likely that myo-inositol is a major lipotrope that lowers triglyceride accumulation via repressed fructolysis and fatty acid synthesis in fatty liver induced by high-

Reduced KHK by Myo-inositol

sucre diets as well as high-fructose diets.

However, the underlying mechanisms by which myo-inositol decreases the expression of KHK and ALDOB genes remains unknown. Several studies have reported that a key lipogenic transcription factor, carbohydrate-responsive element-binding protein (ChREBP), binds to the KHK gene promoter in human hepatocytes, HepG2 cells, and that liver-specific ChREBP-null rats repress high fructose-induced expression of KHK and ALDOB genes. ChREBP is translocated into the nucleus and activated by dephosphorylation at its sites, serine 196 and threonine 666 via protein phosphatase 2A, which is activated in the pentose-phosphate pathway. Several studies have shown that administration of a high-sucrose diet supplemented with myo-inositol in rats lowers hepatic activities of glucose-6-phosphate dehydrogenase, which catalyzes a rate-limiting step of the pentose-phosphate pathway and produces NADPH for fatty acid synthesis, indicating that myo-inositol could repress the dephosphorylation and activation of ChREBP. In addition, we reported that treatment with myo-inositol attenuated high fructose-induced binding of ChREBP to the FAS promoter in the rat liver. Moreover, in vitro studies have shown that inositol phosphates, which are secondary messengers containing myo-inositol as their component, activate histone deacetylases (HDACs), which are transcriptional repressors. Therefore, a decrease in the expression of KHK and ALDOB genes by myo-inositol may be involved in the synergistic inactivation of ChREBP and activation of HDACs. However, this hypothesis requires further investigation.

In contrast to the decreased expression of the fructolytic enzyme genes by myo-inositol, myo-inositol did not affect the expression of GK and PFK genes. Glucose can be taken up by the liver and converted into fatty acids, especially under conditions of excess energy, such as obesity. In this study, feeding rats a high-sucrose diet with or without myo-inositol for 14 d did not significantly increase mesenteric adipose tissue compared with that in rats fed a control diet. This may explain why myo-inositol did not affect the expression of GK and PFK genes. Therefore, further studies should investigate whether intake of myo-inositol decreases the expression of glycolytic enzyme genes in the liver of obese rats fed a high-fat/high-sucrose diet for longer durations.

It should be noted that myo-inositol supplementation reduced the expression of KHK more potently than it did that of ALDOB. Several studies have demonstrated that KHK-knockout mice exhibit improved fatty liver induced by high-fat and high-fat/high-sucrose diets. In addition, Lanaspa et al. showed that KHK/ALDOB-double knockout mice, compared with ALDOB-knockout mice, repressed hepatic inflammation and fibrosis when they were exposed to fructose. Therefore, our data that myo-inositol reduces the expression of KHK prior to that of ALDOB may be useful for the prevention of high-sucrose diet-induced fatty liver and other metabolic diseases, such as insulin resistance and type 2 diabetes.

4 Conclusions

We showed that dietary supplementation with myo-inositol decreases hepatic triglyceride levels and the expression of fructolytic enzyme (KHK and ALDOB) genes and KHK proteins, but not that of glycolytic enzyme (GK and PFK) genes in rats fed a high-fructose diet. The study results suggest that myo-inositol represses primary fructolysis, but not glycolysis, in high-sucrose diet-induced fatty liver.
