NOTE ON BOUNDS FOR MULTIPlicITIES

TIM RÖMER

Abstract. Let $S = K[x_1, \ldots, x_n]$ be a polynomial ring and $R = S/I$ be a graded $K$-algebra where $I \subset S$ is a graded ideal. Herzog, Huneke and Srinivasan have conjectured that the multiplicity of $R$ is bounded above by a function of the maximal shifts in the minimal graded free resolution of $R$ over $S$. We prove the conjecture in the case that $\text{codim}(R) = 2$ which generalizes results in [10] and [13]. We also give a proof for the bound in the case in which $I$ is componentwise linear. For example, stable and squarefree stable ideals belong to this class of ideals.

1. Introduction

Let $S = K[x_1, \ldots, x_n]$ be the polynomial ring with $n$ variables over a field $K$ equipped with the standard grading by setting $\text{deg}(x_i) = 1$. Let $I \subset S$ be a graded ideal and $R = S/I$ be a standard graded $K$-algebra. Consider the minimal graded free resolution of $R$:

$$0 \rightarrow \bigoplus_{j \in \mathbb{Z}} S(-j)^{\beta_{p,j}^S(R)} \rightarrow \cdots \rightarrow \bigoplus_{j \in \mathbb{Z}} S(-j)^{\beta_{1,j}^S(R)} \rightarrow S \rightarrow 0$$

where we denote with $\beta_{i,j}^S(R) = \dim_K \text{Tor}_i^S(R, K)_j$ the graded Betti numbers of $R$ and $p = \text{proj dim}(R)$ is the projective dimension of $R$. The ring $R$ is said to have a pure resolution if at each step there is only a single degree, i.e. the resolution has the following shape:

$$0 \rightarrow S(-d_p)^{\beta_p^S(R)} \rightarrow \cdots \rightarrow S(-d_1)^{\beta_1^S(R)} \rightarrow S \rightarrow 0$$

for some numbers $d_1, \ldots, d_p$.

Let $e(R)$ denote the multiplicity of $R$. Huneke and Miller proved in [15] the following formula:

**Theorem 1.1.** Let $R$ be a Cohen-Macaulay ring with a pure resolution. Then

$$e(R) = (\prod_{i=1}^p d_i)/p!.$$
Conjecture 1.2. Let \( I \subset S \) be a graded ideal, \( R = S/I \) be Cohen-Macaulay and \( p = \text{proj dim}(R) \). Then

\[
\left( \prod_{i=1}^{p} m_i/p! \right) \leq e(R) \leq \left( \prod_{i=1}^{p} M_i/p! \right).
\]

Herzog and Srinivasan proved this conjecture in [13] for several types of ideals: complete intersections, perfect ideals with quasipure resolutions (i.e. \( m_i(R) \geq M_{i-1}(R) \) for all \( i \)), perfect ideals of codimension 2, codimension 3 Gorenstein ideals generated by 5 elements (the upper bound holds for all codimension 3 Gorenstein ideals), codimension 3 Gorenstein monomial ideals with at least one generator of smallest possible degree (relative to the number of generators), perfect stable ideals (in the sense of Eliahou and Kervaire [8]), perfect squarefree strongly stable ideals (in the sense of Aramova, Herzog and Hibi [2]). See also [14] for related results. The lower bound fails to hold in general if \( R \) is not Cohen-Macaulay (see [13] for a detailed discussion). Herzog and Srinivasan conjectured in this case the following inequality:

Conjecture 1.3. Let \( I \subset S \) be a graded ideal, \( R = S/I \) and \( c = \text{codim}(R) \). Then

\[
e(R) \leq \left( \prod_{i=1}^{c} M_i/c! \right).
\]

Since the codimension of a graded \( K \)-algebra is less or equal to the projective dimension and for all \( i \) we have that \( M_i \geq i \), the inequality in Conjecture 1.3 is stronger than the one of Conjecture 1.2.

Herzog and Srinivasan proved this conjecture in the cases of stable ideals, squarefree strongly stable ideals and ideals with a \( d \)-linear resolution, i.e. \( \beta_{i,i+j}(R) = 0 \) for \( j \neq d \). Furthermore Gold [10] established Conjecture 1.3 in the case of codimension 2 lattice ideals. This conjecture is also known to be true for so-called a-stable ideals (see Section 3 for the definition) by Gasharov, Hibi and Peeva [9] which generalizes the stable and squarefree stable case.

In the first part of this paper we show that Conjecture 1.3 is valid for codimension 2 ideals. This generalizes the cases of perfect codimension 2 ideals of Herzog and Srinivasan and codimension 2 lattice ideals of Gold.

For \( d \geq 0 \) let \( I_{(d)} \subseteq I \) be the ideal which is generated by all elements of degree \( d \) in \( I \). Recall from [11] that an ideal \( I \subset S \) is called componentwise linear if for all \( d \geq 0 \) the ideal \( I_{(d)} \) has a \( d \)-linear resolution. We show that the upper bound for the multiplicity holds for componentwise linear ideals which generalizes some of the known cases since for example stable and squarefree stable ideals are componentwise linear. We prove that a-stable ideals are componentwise linear and can also deduce the conjecture in this case.

The author is grateful to Prof. Bruns and Prof. Herzog for inspiring discussions on the subject of the paper.
2. Codimension 2 case

Let $I \subset S$ be a graded ideal and $R = S/I$. In this section we prove Conjecture 1.3 in the case that $\operatorname{codim}(R) = 2$.

The codimension 2 case is known if $R$ is Cohen-Macaulay:

**Theorem 2.1** (Herzog-Srinivasan [13]). Let $I \subset S$ be a graded ideal and $R = S/I$ Cohen-Macaulay with $\operatorname{codim}(R) = 2$. Then

$$e(R) \leq (M_1 \cdot M_2)/2.$$ 

Following [18] or [13] under the name filter regular element) we call an element $x \in R_1$ almost regular for $R$ if

$$(0 :_R x)_a = 0 \text{ for } a \gg 0.$$ 

A sequence $x_1, \ldots, x_t \in R_1$ is an almost regular sequence if for all $i \in \{1, \ldots, t\}$ the element $x_i$ is almost regular for $R/(x_1, \ldots, x_{i-1})R$. It is well-known that, provided $|K| = \infty$, after a generic choice of coordinates we can achieve that a $K$-basis of $R_1$ is almost regular for $R$. (See [13] and [18] for details.)

If $\dim_K(R) = n$ and since neither the Betti numbers nor the multiplicity of $R$ changes by enlarging the field, we always may assume that $x_1, \ldots, x_n \in R_1$ is an almost regular sequence for $R$ to prove Conjecture 1.3. In the following we will not distinguish between an element $x \in S_1$ and the image in $R_1$.

We use almost regular elements to reduce the problem to dimension zero. At first we have to recall some properties of almost regular elements.

**Lemma 2.2.** Let $I \subset S$ be a graded ideal and $R = S/I$. Let $x \in R_1$ almost regular for $R$. If $\dim(R) > 0$, then $\dim(R/xR) = \dim(R) - 1$.

**Proof.** We have the exact sequence

$$0 \to (0 :_R x)(-1) \to R(-1) \xrightarrow{\partial} R \to R/xR \to 0.$$ 

Since $(0 :_R x)$ has finite length and $\dim(R) > 0$ we conclude that $\dim(R/xR) = \dim(R) - 1$. 

**Lemma 2.3.** Let $I \subset S$ be a graded ideal and $R = S/I$. Let $x \in R_1$ be almost regular for $R$. Then

(i) If $\dim(R) > 1$, then $e(R) = e(R/xR)$.

(ii) If $\dim(R) = 1$, then $e(R) \leq e(R/xR)$.

**Proof.** Again we have the exact sequence

$$0 \to (0 :_R x)(-1) \to R(-1) \xrightarrow{\partial} R \to R/xR \to 0.$$ 

In the case $\dim(R) > 1$ we get $e(R) = e(R/xR)$, because $(0 :_R x)$ has finite length. If $\dim(R) = 1$, then

$$e(R) = e(R/xR) - l((0 :_R x)) \leq e(R/xR).$$
Let $K_\ast(k; R)$ denote the Koszul complex and $H_\ast(k; R)$ denote the Koszul homology of $R$ with respect to $x_1, \ldots, x_k \in S$ (see [3] for details). Note that $K_\ast(k; R) = K_\ast(k; S) \otimes_R R$ where $K_\ast(k; S)$ is the exterior algebra on $e_1, \ldots, e_k$ with $\deg(e_i) = 1$ together with a differential $\partial$ induced by $\partial(e_i) = x_i$. For a cycle $z \in K_\ast(k; R)$ we denote with $[z] \in H_\ast(k; R)$ the corresponding homology class. For $k = 0$ we set $H_0(0; R) = R$. Then there are exact sequences relating the Koszul homology groups:

$$\cdots \rightarrow H_i(k; R)(-1) \xrightarrow{x_{k+1}} H_i(k; R) \rightarrow H_i(k + 1; R) \rightarrow H_{i-1}(k; R)(-1) \xrightarrow{x_{k+1}} \cdots \rightarrow H_0(k; R)(-1) \xrightarrow{x_{k+1}} H_0(k; R) \rightarrow H_0(k + 1; R) \rightarrow 0.$$ 

The map $H_i(k; R) \rightarrow H_i(k + 1; R)$ is induced by the inclusion of the corresponding Koszul complexes. Every homogeneous element $z \in K_i(k + 1; R)$ can be uniquely written as $e_{k+1} \cdot z' + z''$ with $z', z'' \in K_i(k; R)$. Then $H_i(k + 1; R) \rightarrow H_{i-1}(k; R)(-1)$ is given by sending $[z]$ to $[z']$. Furthermore $H_i(k; R)(-1) \xrightarrow{x_{k+1}} H_i(k; R)$ is the multiplication map with $x_{k+1}$. Observe that $H_0(k; R) = R/(x_1, \ldots, x_k)R$. As noticed above we may assume that the image of $x_1, \ldots, x_n \in S_1$ in $R_1$ is an almost regular sequence for $R$. In this case the modules $H_i(k; R)$ all have finite length for $i > 0$.

We are able to extend Theorem 2.1 to the general case, which also generalizes the main result in [10].

**Theorem 2.4.** Let $I \subset S$ be a graded ideal and $R = S/I$ with $\operatorname{codim}(R) = 2$. Then

$$e(R) \leq (M_1 \cdot M_2)/2.$$

**Proof.** Let $x = x_1, \ldots, x_{n-2}$ and consider $\tilde{R} = R/xR$. Notice that by 2.2 and 2.3 we have that $e(R) \leq e(\tilde{R})$ and $2 = \operatorname{codim}(R) = \operatorname{codim}(\tilde{R})$. Observe that $\tilde{R} = \tilde{S}/\tilde{I}$, where $\tilde{S}$ is the 2-dimensional polynomial ring $S/xS$ and $\tilde{I} = (I + (x))/(x)$. Let

$$M_i = \max\{j \in \mathbb{Z} : \beta_{i,j}^S(R) \neq 0\} \text{ for } i = 1, 2$$

and

$$\tilde{M}_i = \max\{j \in \mathbb{Z} : \beta_{i,j}^S(\tilde{R}) \neq 0\} \text{ for } i = 1, 2.$$ 

We claim that

(1) \quad $\tilde{M}_1 \leq M_1$ and $\tilde{M}_2 \leq M_2$.

Since $\dim(\tilde{R}) = 0$, the ring $\tilde{R}$ is Cohen-Macaulay. Thus it follows from 2.1 that

$$e(R) \leq e(\tilde{R}) \leq (\tilde{M}_1 \cdot \tilde{M}_2)/2 \leq (M_1 \cdot M_2)/2.$$ 

It remains to prove claim (1). The first inequality can easily be seen: $\tilde{M}_1$ is the maximal degree of a minimal generator of $\tilde{I}$ and $M_1$ is the maximal degree of a minimal generator of $I$. Since $\tilde{I} = (I + (x))/(x)$ we get that

$$\tilde{M}_1 \leq M_1.$$ 

Next we prove the second inequality $\tilde{M}_2 \leq M_2$. Let $H_\ast(k; R)$ denote the Koszul homology of $R$ with respect to $x_1, \ldots, x_k \in S$ for $k = 1, \ldots, n$ and $\tilde{H}_\ast(l; \tilde{R})$ denote
the Koszul homology of $\tilde{R}$ with respect to $x_{n-2+1}, \ldots, x_{n-2+l} \in S$ for $l = 1, 2$. We denote with
$$M_{i,k} = \max\{j \in \mathbb{Z}: H_i(k; \tilde{R})_j \neq 0\} \cup \{0\}$$
for $i = 1, 2$ and $k = 1, \ldots, n$. And
$$\tilde{M}_{i,l} = \max\{j \in \mathbb{Z}: \tilde{H}_i(l; \tilde{R})_j \neq 0\} \cup \{0\}$$
for $i = 1, 2$ and $l = 1, 2$.

Observe that these numbers are well-defined since all considered modules have finite length. Note that $M_{i,n} = M_i$ and $\tilde{M}_{i,2} = \tilde{M}_i$ for $i = 1, 2$. We have to show that
$$\tilde{M}_{2,2} \leq M_{2,n}.$$

Since $H_0(n-2; \tilde{R}) = \tilde{R}$ there is the long exact sequence of Koszul homology groups
$$\cdots \to H_1(n-2; \tilde{R}) \to H_1(n-1; \tilde{R}) \to \tilde{R}(\sim 1) \xrightarrow{x_n-1} \tilde{R} \to \tilde{R}/(x_{n-1})\tilde{R} \to 0.$$

We also have an exact sequence
$$0 \to \tilde{H}_1(1; \tilde{R}) \to \tilde{R}(\sim 1) \xrightarrow{x_n-1} \tilde{R} \to \tilde{R}/(x_{n-1})\tilde{R} \to 0.$$

We get a surjective homomorphism $H_1(n-1; \tilde{R}) \to \text{Ker}(\tilde{R}(\sim 1) \xrightarrow{x_n-1} \tilde{R})$ and an isomorphism $\tilde{H}_1(1; \tilde{R}) \cong \text{Ker}(\tilde{R}(\sim 1) \xrightarrow{x_n-1} \tilde{R})$ of graded $K$-vector spaces. Hence
$$\tilde{M}_{1,1} \leq M_{1,n-1}.$$

Next we consider the exact sequence
$$\cdots \to H_2(n; \tilde{R}) \to H_1(n-1; \tilde{R})(\sim 1) \xrightarrow{x_n} H_1(n-1; \tilde{R}) \to H_1(n; \tilde{R}) \to \cdots$$

Since $H_1(n-1; \tilde{R})_{M_{1,n-1}+1} = 0$ we have a surjective map
$$H_2(n; \tilde{R})_{M_{1,n-1}+1} \to H_1(n-1; \tilde{R})_{M_{1,n-1}}.$$

By definition of the number $M_{1,n-1}$ we have that $H_1(n-1; \tilde{R})_{M_{1,n-1}} \neq 0$. It follows that $H_2(n; \tilde{R})_{M_{1,n-1}+1} \neq 0$ and therefore
$$M_{1,n-1} + 1 \leq M_{2,n}.$$

We also have an exact sequence
$$0 \to \tilde{H}_2(2; \tilde{R}) \to \tilde{H}_1(1; \tilde{R})(\sim 1) \xrightarrow{x_n} \tilde{H}_1(1; \tilde{R}) \to \tilde{H}_1(2; \tilde{R}) \to \cdots$$

Note that $\tilde{H}_1(1; \tilde{R})_{\tilde{M}_{2,1}+1} = 0$. Considering the sequence in degree $\tilde{M}_{1,1} + 1$ we get an isomorphism $\tilde{H}_2(2; \tilde{R})_{\tilde{M}_{1,1}+1} \cong \tilde{H}_1(1; \tilde{R})_{\tilde{M}_{1,1}} \neq 0$ and thus $\tilde{M}_{1,1} + 1 \leq \tilde{M}_{2,2}$. In degree $\tilde{M}_{2,2}$ we obtain the injective map $0 \to \tilde{H}_2(2; \tilde{R})_{\tilde{M}_{2,2}} \to \tilde{H}_1(1; \tilde{R})_{\tilde{M}_{2,2}-1}$. Since by definition of the number $\tilde{M}_{2,2}$ we have that $\tilde{H}_2(2; \tilde{R})_{\tilde{M}_{2,2}} \neq 0$, it follows that $\tilde{H}_1(1; \tilde{R})_{\tilde{M}_{2,2}-1} \neq 0$ and therefore $\tilde{M}_{2,2} \leq \tilde{M}_{1,1} + 1$. Hence
$$\tilde{M}_{2,2} = \tilde{M}_{1,1} + 1.$$

All in all we have shown that
$$M_2 = M_{2,2} = \tilde{M}_{1,1} + 1 \leq M_{1,n-1} + 1 \leq M_{2,n} = M_2$$

which is the second part of the desired inequalities of (ii). Thus we proved (ii) and this concludes the proof. □
3. Componentwise linear ideals

In this section we prove Conjecture 1.3 for componentwise linear ideals. We first introduce some notation and recall some definitions. (For unexplained notation see \cite{6}.) Given a finitely generated $S$-module $M \neq 0$ and $i, j \in \mathbb{Z}$ we denote with $\beta_{i,j}(M) = \dim_K \text{Tor}_i^S(M, K)_j$ the graded Betti numbers of $M$. Let

\[ \text{proj dim}(M) = \max\{i \in \mathbb{Z}: \beta_{i,i+j}(M) \neq 0 \text{ for some } j\} \]

be the projective dimension and

\[ \text{reg}(M) = \max\{j \in \mathbb{Z}: \beta_{i,i+j}(M) \neq 0 \text{ for some } i\} \]

be the Castelnuovo-Mumford regularity of $M$.

For $a = (a_1, \ldots, a_n) \in \mathbb{N}^n$ and a monomial $x_1^{a_1} \cdots x_n^{a_n} \in S$ we set $x^a$. Let $|a| = a_1 + \cdots + a_n$ and $\text{supp}(a) = \{i: a_i \neq 0\} \subseteq [n] = \{1, \ldots, n\}$. A simplicial complex $\Delta$ on the vertex set $[n]$ is a collection of subsets of $[n]$ such that $\{i\} \in \Delta$ for $i = 1, \ldots, n$, and $F \in \Delta$ whenever $F \subseteq G$ for some $G \in \Delta$. For $F \in \Delta$ we define $\dim(F) = |F| - 1$ where $|F| = |\{i \in F\}|$ and $\dim(\Delta) = \max\{\dim(F): F \in \Delta\}$. Then $F \in \Delta$ is called an $i$-face if $i = \dim(F)$. Faces of dimension 0, 1 are called vertices and edges respectively. The maximal faces under inclusion are called the facets of the simplicial complex. Note that $\emptyset$ is also a face of dimension $-1$. For $i = 1, \ldots, \dim(\Delta)$ we define $f_i$ to be the number of $i$-dimensional faces of $\Delta$.

We denote with $\Delta^* = \{F: F^c \not\in \Delta\}$ the Alexander dual of $\Delta$ where $F^c = [n] \setminus F$. This is again a simplicial complex. For $F = \{i_1, \ldots, i_s\} \subseteq [n]$ we also write $x_F$ for the monomial $\prod_{i \in F} x_i$. These monomials are also called squarefree monomials. Then $K[\Delta] = S/I_\Delta$ is the Stanley-Reisner ring of $\Delta$ where

\[ I_\Delta = (x_F: F \subseteq [n], F \not\in \Delta) \]

is the Stanley-Reisner ideal of $\Delta$. Observe that $\dim(K[\Delta]) = \dim(\Delta) + 1$. (See \cite{6} for details.) At first we relate some of the considered invariants. For a graded ideal $I \subseteq S$ let

\[ a(I) = \min\{d \in \mathbb{Z}: \beta^{S}_{0,d}(I) \neq 0\} \]

be the initial degree of $I$.

**Lemma 3.1.** Let $\Delta$ be a $(d - 1)$-dimensional simplicial complex. Then:

(i) $e(S/I_\Delta) = \beta^S_{0,a(I_\Delta^*)}(I_\Delta^*)$.

(ii) $\text{codim}(S/I_\Delta) = a(I_\Delta^*)$.

(iii) $\text{proj dim}(S/I_\Delta) = \text{reg}(I_\Delta^*)$.

**Proof.** Observe that $F \in \Delta$ is a facet if and only if $x_{F^c}$ is a minimal generator of $I_\Delta^*$. Hence $F$ has maximal dimension $d - 1$ if and only if $x_{F^c}$ is a minimal generator of $I_\Delta^*$ of minimal degree. It follows that

\[ a(I_\Delta^*) = n - d \text{ and } \beta^S_{0,a(I_\Delta^*)}(I_\Delta^*) = f_{d-1}^d. \]

(i): We know that $e(S/I_\Delta) = f_{d-1}^d$. (For example combine 4.1.9 and 5.1.9 in \cite{6}.) Thus $e(S/I_\Delta) = \beta^S_{0,a(I_\Delta^*)}(I_\Delta^*)$. 

(ii): This follows from
\[
\text{codim}(S/I_\Delta) = n - \dim(S/I_\Delta) = n - \dim(\Delta) - 1 = n - d = a(I_\Delta^*).
\]

(iii): This is a result of Terai in [17]. □

Recall that an ideal \( I \subset S \) is called a monomial ideal if it is generated by monomials of \( S \). We denote with \( G(I) \) the unique minimal system of generators for \( I \).

A monomial ideal \( I \subset S \) is called squarefree strongly stable, if it is generated by squarefree monomials such that for all \( x_F \in G(I) \) and \( i \) with \( x_i \mid x_F \) we have for all \( j < i \) with \( x_j \nmid x_F \) that \((x_F/x_i)x_j \in I\).

Note that for a simplicial complex \( \Delta \) we have that \( I_\Delta \) is squarefree strongly stable if and only if \( I_\Delta^* \) is squarefree strongly stable.

We give a new proof for the bound of the multiplicity in the case of squarefree strongly stable ideals which avoids the calculations of the original proof in [13].

**Theorem 3.2.** Let \( \Delta \) be a simplicial complex such that \( I_\Delta \) is a squarefree strongly stable ideal and \( c = \text{codim}(S/I_\Delta) \). Then
\[
e(S/I_\Delta) \leq \left( \prod_{i=1}^{c} M_i \right) / c!.
\]

**Proof.** Let \( b(S/I_\Delta) = \max \{ i \in \mathbb{Z} : \beta_{i, \text{reg}(S/I_\Delta)}^S(S/I_\Delta) \neq 0 \} \). Since \( I_\Delta \) and \( I_\Delta^* \) are squarefree strongly stable ideals, it follows from Theorem 3.8 below that
\[
\beta_{i, \text{reg}(S/I_\Delta)}^S(S/I_\Delta) \neq 0 \text{ for } i = 1, \ldots, b(S/I_\Delta) \text{ and }
\]
\[
\beta_{0, a(I_\Delta^*)}^S(I_\Delta^*) \leq \frac{\text{proj dim}(I_\Delta^*) + a(I_\Delta^*)}{a(I_\Delta^*)}.
\]

Let \( p = \text{proj dim}(I_\Delta^*) \). We have that
\[
\text{codim}(S/I_\Delta) = a(I_\Delta^*) \leq \max \{ j \in \mathbb{Z} : \beta_{p, j}^S(I_\Delta^*) \neq 0 \} = b(S/I_\Delta)
\]
where the last equality follows from Theorem 2.8 in [5]. (These numbers describe certain “extremal Betti numbers” of the considered modules.)

Hence we get that
\[
M_i = \text{reg}(S/I_\Delta) + i \text{ for } i = 1, \ldots, \text{codim}(S/I_\Delta).
\]

Together with the results of Lemma 3.1 we obtain
\[
e(S/I_\Delta) = \beta_{0, a(I_\Delta^*)}^S(I_\Delta^*) \leq \left( \frac{\text{proj dim}(I_\Delta^*) + a(I_\Delta^*)}{a(I_\Delta^*)} \right)
\]
\[
= \left( \frac{\text{reg}(S/I_\Delta) + \text{codim}(S/I_\Delta)}{\text{codim}(S/I_\Delta)} \right) = \left( \prod_{i=1}^{\text{codim}(S/I_\Delta)} M_i \right) / \text{codim}(S/I_\Delta)!
\]

For an arbitrary graded ideal we can prove a weaker bound than the one of Conjecture 1.3 which was already noticed in [13]. We also get a bound for the codimension of the considered ideal.
Corollary 3.3. Let \( \text{char}(K) = 0 \), \( I \subset S \) be a graded ideal, \( R = S/I \) and \( c = \text{codim}(R) \). Then

\[
\begin{align*}
(i) \quad & c \leq \max \{ i \in \mathbb{Z} : \beta^S_{i,i+\text{reg}(S/I)}(S/I) \neq 0 \}, \\
(ii) \quad & e(R) \leq \binom{\text{reg}(R)+c}{c}. 
\end{align*}
\]

Proof. Let again

\[
b(S/I) = \max \{ i \in \mathbb{Z} : \beta^S_{i,i+\text{reg}(S/I)}(S/I) \neq 0 \}.
\]

By replacing \( I \) with the generic initial ideal \( \text{Gin}(I) \) with respect to the reverse lexicographic order of \( I \) (see for example [7] for details) we do not change the multiplicity and the codimension. Furthermore by Theorem 2.8 in [5] also the number \( b(S/I) \) does not change. This means we may assume that \( I \) is a monomial ideal.

By polarization we get a Stanley-Reisner Ideal \( I_{\Delta} \) for some complex \( \Delta \) with the same Betti diagram as \( I \) and also the multiplicity, codimension do not change. Hence we may assume that \( I = I_{\Delta} \).

Now we replace \( I_{\Delta} \) by the Stanley-Reisner ideal of the associated simplicial complex with respect to symmetric or algebraic shifting. Again the multiplicity, codimension and \( b(S/I_{\Delta}) \) do not change and we may assume that \( I_{\Delta} \) is a squarefree strongly stable ideal. (See [4] for details on shifting operations.)

In the proof of Theorem 3.2 we showed in fact that for a squarefree strongly stable ideal the desired bounds of (i) and (ii) hold. This concludes the proof. \( \square \)

Remark 3.4. It can also be shown that the bound for the multiplicity of Corollary 3.3 is valid if \( \text{char}(K) > 0 \). This can be proved analogously to the discussion before Corollary 3.8 in [13].

In a special case we can prove Conjecture 1.3.

Corollary 3.5. Let \( I \subset S \) be a graded ideal, \( R = S/I \), \( c = \text{codim}(R) \) and suppose that \( M_i = \text{reg}(R) + i \) for \( i = 1, \ldots, c \). Then

\[
e(R) \leq \frac{\prod_{i=1}^c M_i}{c!}.
\]

Remark 3.6. Corollary 3.5 does not imply the upper bound for the multiplicity in Conjecture 1.3 in full generality. For example even for complete intersections with ideals generated in degree \( \geq 2 \) the assumptions of the corollary are not satisfied.

But several known cases besides squarefree strongly stable ideals are included in this result. For example the following cases which were originally proved in [13] with different proofs for each type of ideal:

(i) \( I \) is a stable ideal.
(ii) \( I \) is a squarefree stable ideal.
(iii) \( I \) has a linear resolution.

Next we generalize these results to the case of componentwise linear ideals.

In the following we fix a field \( K \) with \( \text{char}(K) = 0 \). Recall that an ideal \( I \) is called componentwise linear, if for all \( d \geq 0 \) the ideal \( I(d) \) has a \( d \)-linear resolution.
Theorem 3.7. Let $I \subset S$ be a componentwise linear ideal, $R = S/I$ and $c = \text{codim}(R)$. Then
\[ e(R) \leq \left( \prod_{i=1}^{c} M_i \right)/c!. \]

Proof. Aramova, Herzog and Hibi [3] proved that an ideal $I$ is componentwise linear if and only if $\beta^S_{i,j}(I) = \beta^S_{i,j}(\text{Gin}(I))$ for all $i, j \in \mathbb{Z}$ where $\text{Gin}(I)$ is the generic initial ideal of $I$ with respect to the reverse lexicographic order. We know that $\text{Gin}(I)$ is stable (see [7]). Then the Eliahou-Kervaire resolution of $\text{Gin}(I)$ (see also 3.8 below) and 3.3 (i) imply that
\[ M_i(S/\text{Gin}(I)) = \text{reg}(S/\text{Gin}(I)) + i \text{ for } i = 1, \ldots, \text{codim}(S/\text{Gin}(I)). \]
Thus we can apply Corollary 3.5 to conclude the proof. $\square$

We introduce a large class of componentwise linear ideals. We fix a vector $a = (a_1, \ldots, a_n)$ where $2 \leq a_i \leq \infty$. The following type of ideal was defined in [9] and [16]: Let $I \subset S$ be a monomial ideal. $I$ is said to be $a$-bounded if for all $x^u \in G(I)$ and all $i \in [n]$ one has $u_i < a_i$. The ideal $I$ is called $a$-stable if, in addition for all $x^u \in G(I)$ and all $j \leq m(u) = \max\{i \in [n]: u_i \neq 0\}$ with $u_j < a_j - 1$, we have that $x_jx^u/x_{m(u)} \in I$. It is easy to see that if $I$ is $a$-stable, then for all $x^u \in I$ and all $j \leq m(u)$ with $u_j < a_j - 1$ we have that $x_jx^u/x_{m(u)} \in I$. If $I$ is $a$-stable with $a = (2, \ldots, 2)$, then $I$ is exactly squarefree stable. For $a = (\infty, \ldots, \infty)$ we obtain a stable ideal in the usual sense.

Let $a, b \in \mathbb{Z}$. We make the convention that $a \choose b = 0$ unless $0 \leq b \leq a$. If $x^u \in S$ with $u \prec a$, then we define
\[ l(u) = |\{i: u_i = a_i - 1, i < m(u)\}|. \]
The following Theorem was proved in [9] and [16].

Theorem 3.8. Let $I \subset S$ be an $a$-stable ideal and $i, j \in \mathbb{Z}$. One has, independent of the characteristic of $K$,
\[ \beta^S_{i,i+j}(I) = \sum_{x^u \in G(I), |u| = j} \binom{m(u) - 1 - l(u)}{i}. \]

As a consequence we are able to determine the regularity for $a$-stable ideals.

Corollary 3.9. Let $I \subset S$ be an $a$-stable ideal. Then
\[ \text{reg}(I) = \max\{|u|: x^u \in G(I)\}. \]
In particular, if $I$ is generated in degree $d$, then $I$ has a $d$-linear resolution.

Corollary 3.10. Let $I \subset S$ be an $a$-stable ideal, $R = S/I$ and $c = \text{codim}(I)$. Then
\[ e(R) \leq \left( \prod_{i=1}^{c} M_i \right)/c!. \]

Proof. Apply 3.5 and 3.8. $\square$

We can prove a little bit more:
Theorem 3.11. Let $I \subseteq S$ be an $a$-stable ideal. Then $I$ is componentwise linear.

Proof. For $k \in \mathbb{N}$ let $I_{\leq k} \subseteq S$ be the ideal which is generated by all homogeneous polynomials of $I$ of degree at most $k$.

We use the following criterion from [12]: a monomial ideal $I$ is componentwise linear if and only if $\text{reg}(I_{\leq k}) \leq k$ for all $k \in \mathbb{N}$. Let $I$ be an $a$-stable ideal. Then for all $k$ the ideal $I_{\leq k}$ is $a$-stable. By 3.9 we have $\text{reg}(I_{\leq k}) \leq k$. This concludes the proof. □
