The General Adversary Bound: A Survey

Lily Li  Morgan Shirley

April 14, 2021

Abstract

Ben Reichardt showed in a series of results that the general adversary bound of a function characterizes its quantum query complexity. This survey seeks to aggregate the background and definitions necessary to understand the proof. Notable among these are the lower bound proof, span programs, witness size, and semi-definite programs. These definitions, in addition to examples and detailed expositions, serve to give the reader a better intuition of the graph-theoretic nature of the upper bound. We also include an applications of this result to lower bounds on DeMorgan formula size.

1 Introduction

Given a function $f$, the quantum query complexity of $f$, denoted $Q_2(f)$, is the number of quantum oracle queries necessary to evaluate $f$. It is typically used as a lower bound on the complexity of a quantum algorithm: the amount of computation allowed between queries is unbounded, so the analysis can be much simpler. The polynomial method [Bea+01] and the adversary bound method [Amb02; BSS03] are common techniques used to show lower bounds on quantum query complexity. However, these techniques are currently incomparable; on the $n$-input collision problem, the adversary method only achieves an $O(1)$ lower bound while the polynomial method achieves the optimal $\Theta(n^{1/3})$ bound while on Ambainis’ total function $f^k$ on $4^k$ bits, the polynomial method achieves at most a $2^k$ lower bound which is strictly weaker than the adversarial bound of $2.5^k$ [Amb06].

The adversary bound was originally proposed by Ambainis [Amb02]. Given a boolean function $f$, the adversary bound of $f$, denoted $\text{Adv}(f)$, captures the intuition that, in order to compute $f$, one must be able to distinguish between any two inputs $w$ and $x$ where $f(w) \neq f(x)$. Specifically, if $|\phi_w\rangle$ and $|\phi_x\rangle$ are the final state of a quantum query algorithm after running with inputs $w$ and $x$ respectively, then $|\phi_w\rangle$ and $|\phi_x\rangle$ must be far apart in our measurement basis if $f(w) \neq f(x)$.

There are several equivalent formulations of the bound. This survey uses the spectral norm formulation of Barnum, Saks, and Szegedy [BSS03].

Definition 1.1. An adversary matrix for $f : \{0,1\}^n \rightarrow \{0,1\}$ is a $2^n$-by-$2^n$ Hermitian matrix $\Gamma$ where $\langle x|\Gamma|y \rangle = 0$ whenever $f(x) = f(y)$.

Definition 1.2. The matrix $D_i$ is the $2^n$-by-$2^n$ matrix where $\langle x|D_i|y \rangle = 0$ if $x_i = y_i$ and $\langle x|D_i|y \rangle = 1$ if $x_i \neq y_i$.

Definition 1.3. The adversary bound on a function $f : \{0,1\}^n \rightarrow \{0,1\}$ is

$$\text{Adv}(f) = \max_{\Gamma \geq 0, \Gamma \neq 0} \frac{\|\Gamma\|}{\max_i \|\Gamma \circ D_i\|}$$

where $\Gamma$ is an adversary matrix for $f$.

In the above definition, $\Gamma \geq 0$ indicates that all entries of $\Gamma$ are non-negative, and the operator $\circ$ denotes entry-wise product. As mentioned above, the adversary bound lower-bounds quantum query complexity.

Theorem 1.4 ([BSS03]). \text{Adv}(f) = \Omega(Q_2(f)).

Furthermore, Laplante, Lee, and Szegedy show that the adversary bound of a function is a lower bound on the square root of the function’s De Morgan formula size.

Theorem 1.5 ([LLS06]). \text{Adv}(f) \leq \sqrt{L_f}

Høyer, Lee, and Špalek [HLS07] removed the non-negativity requirement from the adversary bound and showed that it remained a lower bound on quantum query complexity and formula size. In fact this generalization only strengthened the lower bound – it is a tight bound on quantum query complexity, although this was not shown until later by Reichardt [Rei11].

Definition 1.6. The general adversary bound on a function $f : \{0,1\}^n \rightarrow \{0,1\}$ is

$$\text{Adv}^+(f) = \max_{\Gamma \neq 0} \frac{\|\Gamma\|}{\max_i \|\Gamma \circ D_i\|}$$

where $\Gamma$ is an adversary matrix for $f$.

\[1\]We assume familiarity with bra-ket notation, which is used here and elsewhere in the survey.
Unlike the matching lower bound, which has a relatively simple proof, the upper bound is proved using deceptively simple algorithms with complicated analyses. Key to this analysis is the span program model of computation [KW93]. Reichardt’s main result is the following:

**Theorem 1.7.** (General Adversary Bound Characterize Quantum Query Complexity.) For any n-ary boolean function $f$,

$$Q_2(f) = \Theta(\text{Adv}^+(f)).$$

Perhaps surprisingly, this result about quantum computing has been used recently in entirely classical settings. From the work of Ambainis et al. [Amb+10], any function with de Morgan formula size $\ell$ has a quantum query algorithm which makes at most $O(\sqrt{\ell})$ queries. In combination with the polynomial method, this implies the existence of a polynomial $p$ with degree $O(\sqrt{\ell})$ such that $p(x)$ approximates $f$ up to a constant factor. More recently, Tal used the result to show a $\tilde{\Omega}(n^2)$ lower bound for the bipartite formula size of the Inner-Product function [Tal17].

### 2 Preliminaries

Let $f$ be an $n$-ary boolean function. Then $F_0 = f^{-1}(0)$ and $F_1 = f^{-1}(1)$ are sets of strings which evaluate to 0 and 1 on $f$ respectively.

We assume basic familiarity with quantum computation and bra-ket notation. Given a vector $|v\rangle$, let $||v||$ represent the $\ell_2$-norm of $|v\rangle$. Given a matrix $M$, let $||M||$ represent the spectral norm of the matrix, defined as $\max_{|u\rangle} ||M|u\rangle||$ where the maximum is over unit vectors $|u\rangle$. In this survey, we use the fact that $||M||$ is the largest singular value of $M$. For two matrices $A$ and $B$, their entry-wise product is denoted $A \circ B$ and their entry-wise inner product is denoted $\langle A, B \rangle$. The trace of a square matrix is the sum of its eigenvalues (including multiplicities). In this survey we make use of the fact that $||\langle M, B \rangle|| = \text{Tr}(M^*B)$ when $M$ and $B$ are square matrices with the same dimension.

Let the trace norm of a matrix $M$ be $||M||_{\text{Tr}} = \max_B ||\langle M, B \rangle||/||B||$ i.e. the maximization of the trace of $M$ over all complex matrices with the same dimensions as $M$. Another standard definition of the trace norm is $||M||_{\text{Tr}} = \text{Tr}(\sqrt{M^*M})$. These definitions are equivalent, which can be proved by observing that the spectral norm is the Schatten $\infty$-norm and the trace norm is the Schatten 1-norm, and using the fact that, for $\frac{1}{p} + \frac{1}{q} = 1$, the Schatten $p$-norm of $M$ is $\max_B ||\langle M, B \rangle||$ divided by the Schatten $q$-norm of $B$. The Frobenius norm of a matrix $M$, denoted $||M||_F$, is $\sqrt{\sum_{x,y} \langle x|M|y\rangle^2}$. We use the fact that the Frobenius norm is the Schatten 2-norm.

For a matrix $A$, we say that $A \in \mathbb{L}(U, V)$ if $A$ is a linear transformation from vectors in $\mathbb{C}^U$ to vectors in $\mathbb{C}^V$. In this case $A$ has $|U|$ columns and $|V|$ rows. Let $\mathbb{L}(U) = \mathbb{L}(U, U)$. $I_k$ is the $k \times k$ identity matrix. When the dimensions are clear from context, we omit the subscript. For $i \in U$ and $j \in V$, we will use $|i\rangle$ and $|j\rangle$ to denote the indicator vectors for the relevant column and row of $A$ respectively. In particular, $\langle i|A|j\rangle$ is the entry of $A$ in row $i$ and column $j$.

Readers will also require some familiarity with positive semi-definite matrix (PSD) and semi-definite programs (SDP). If $X$ is PSD, we write $X \succeq 0$. When we write $X \succeq Y$, we mean $X - Y \succeq 0$.

### 3 The General Adversary Bound

In this section we show the following properties of the general adversary bound.
Theorem 3.1 ([HLS07]). \( \text{Adv}^\pm(f) = \Omega(Q_2(f)) \).

Theorem 3.2 ([HLS07]). \( \text{Adv}^\pm(f) \leq \sqrt{L_f} \)

The corresponding upper bound, \( \text{Adv}^\pm(f) = O(Q_2(f)) \), will be left to a later section.

3.1 \( \text{Adv}^\pm \) is a Lower Bound for Quantum Query Complexity

Consider a quantum query algorithm that computes \( f \) in \( T \) steps with error at most 1/3. Without loss of generality, the quantum query algorithm is of the form \( U_TV_{\text{IND}}U_{T-1}V_{\text{IND}} \cdots U_1V_{\text{IND}}U_0 \) where each \( U_i \) is a unitary that does not depend on the input \( x \) and \( V_{\text{IND}} \) is the standard phase oracle unitary on the index function \( \text{IND} \):
\[
V_{\text{IND}}|i\rangle = (-1)^x|i\rangle
\]

It will be helpful to divide the state of this quantum query algorithm into three sets of qubits: (1) the input set \( I \) holds the input \( x \) and remains unchanged throughout the execution of the algorithm, (2) the query set \( Q \) that is used by each \( V_{\text{IND}} \) to specify a coordinate of \( x \), and (3) a workspace set \( W \) that can be acted upon arbitrarily. The qubits in \( Q \) and \( W \) are measured at the end of the algorithm to obtain an output in \( \{0,1\} \). These measurements can be viewed as orthogonal projectors \( \Pi_0, \Pi_1 \). Let the combined state of \( Q \) and \( W \) on input \( x \) at step \( t \) be \( |\psi_x^t\rangle \). Further define the matrix \( \Psi^t \) to be the \( 2^n \times (|Q| + |W|) \) matrix with \( |\psi_x^t\rangle \) as rows. Then the probability that we will measure outcome \( b \) on input \( x \) is \( \|\Pi_b|\psi_x^T\rangle\|^2 \). Note that for all \( x \) we have \( \|\Pi_{f(x)}|\psi_x^T\rangle\|^2 \geq 2/3 \). Three other important properties of the projectors are that \( \Pi_0 + \Pi_1 = \mathbb{I} \) (the projectors are complete), \( \Pi_b^2 = \Pi_b \) (performing a projection twice has no more effect than applying it once), and \( \Pi_0 \Pi_1 = \Pi_1 \Pi_0 = 0 \) (the projections are orthogonal).

The main observation that Hoyer, Lee, and Špalek [HLS07] use in their proof of Theorem 3.1 is that the combined state of \( Q \) and \( W \) must be very different when the algorithm is run on \( x \) compared to when it is run on \( y \) if \( f(x) \neq f(y) \); otherwise, any measurement would be unable to distinguish these states with high enough fidelity. We present their argument here.

Proof of Theorem 3.1. Let \( \Gamma \) be an adversary matrix. Note that \( \|\Gamma\| \) is the largest absolute value of any eigenvalue of \( \Gamma \), as \( \Gamma \) is Hermitian. Assume that \( \|\Gamma\| = \lambda_1 \) where \( \lambda_1 \) is the largest eigenvalue of \( \Gamma \): this can be done without loss of generality by replacing \( \Gamma \) with \( (−1)\Gamma \), which does not affect the value of \( \|\Gamma\| \). Let \( |\delta\rangle \) be the unit eigenvector corresponding to \( \lambda_1 \).

Consider running our quantum query algorithm for \( f \) with an input in a superposition defined by \( |\delta\rangle \): the state of the input qubits will be \( \sum_{x \in \{0,1\}^n} \langle x|\delta\rangle |x\rangle \). Then the state of \( Q \) and \( W \) at step \( t \) will be \( \sum_{x \in \{0,1\}^n} \langle x|\delta\rangle |\psi_x^t\rangle \). Let \( W(t) \) be the \( 2^n \)-by-\( 2^n \) density matrix defined by \( \langle x|W(t)|y\rangle = \langle x|\delta\rangle \langle \delta|y\rangle \langle \psi_y^t|\psi_x^t\rangle \).

Equivalently, \( W(t) = |\delta\rangle \langle \delta| \circ \Psi^t(\Psi^t)^* \). We measure the progress of the algorithm by comparing \( W(t) \) to \( \Gamma \). Define the progress measure \( M(t) = \langle \Gamma, W(t) \rangle \). To prove the lower bound, it suffices to show that this progress measure changes by an amount bounded above by \( 2\max_i \|\Gamma \circ D_i\| \) at each step of the algorithm, but must change by at least a constant multiple of \( \|\Gamma\| \) over the course of the entire algorithm. The following three claims show this.

Claim 3.3. \( M(0) = \|\Gamma\| \)

Proof. Before any executions of the phase oracle, the state cannot depend on the input: for all \( x \) and \( y \), \( |\psi_x^0\rangle = |\psi_y^0\rangle \), and so \( W(0) = |\delta\rangle \langle \delta| \). Then \( M(0) = \langle \Gamma, |\delta\rangle \langle \delta| \rangle = \text{Tr}(\Gamma^* |\delta\rangle \langle \delta|) = \text{Tr}(\lambda_1 |\delta\rangle \langle \delta|) = \lambda_1 \cdot 1 = \|\Gamma\|. \)

Claim 3.4. \( M(t) \leq \left( \frac{1}{\sqrt{2}} \right) \|\Gamma\| \)

\( ^2 \)To see that \( W(t) \) is indeed a density matrix, note that it is the Gram matrix of \( \{\langle x|\delta\rangle |\psi_x^t\rangle \} \).

\( \sqrt{2} \)
Proof. First note that \( \Gamma = \Gamma \circ F \) where \( F \) is the 0/1 adversary matrix:

\[
\langle x | F | y \rangle = \begin{cases} 
0 & f(x) = f(y) \\
1 & f(x) \neq f(y) 
\end{cases}
\]

Thus \( M^{(T)} = (\Gamma \circ F, W^{(T)}) = (\Gamma, F \circ W^{(T)}) \). By the definition of the trace norm, this gives us \( M^{(T)} \leq \| \Gamma \| \| F \circ W^{(T)} \|_{TV} \). To prove the claim we simply need to upper-bound \( \| F \circ W^{(T)} \|_{TV} \).

Let \( X_0 \) (respectively \( X_1 \)) be the \( 2^n \times 2^n \) matrix where the \( x \)th row is (the conjugate of) \( \Pi_{f(x)} \delta_x | \psi_x^T \rangle \) (respectively \( \Pi_{1-f(x)} \delta_x | \psi_x^T \rangle \)). Intuitively, \( X_0 \) is the projection onto the correct answers and \( X_1 \) is the projection onto the incorrect answers.

Observe that \( F \circ W^{(T)} = X_0 X_1^* + X_1 X_0^* \):

\[
\langle x | (X_0 X_1^* + X_1 X_0^*) | y \rangle = \langle x | \delta \rangle \langle \delta | y \rangle \left( \langle \psi_y^T | \Pi_{1-f(y)} \Pi_{f(x)} | \psi_x^T \rangle + \langle \psi_y^T | \Pi_{f(y)} \Pi_{1-f(x)} | \psi_x^T \rangle \right).
\]

If \( f(x) = f(y) \), then the expression on the right is 0, as \( \Pi_0 \Pi_1 = 0 \). Otherwise, \( \Pi_0 \Pi_0 = \Pi_0 \) and \( \Pi_0 + \Pi_1 = I \), so the expression on the right is \( \langle x | \delta \rangle \langle \delta | y \rangle \langle \psi_y^T | \psi_x^T \rangle = \langle x | W^{(T)} | y \rangle \).

We now need to upper-bound \( \| X_0 X_1^* + X_1 X_0^* \|_{TV} \).

\[
\| X_0 X_1^* + X_1 X_0^* \|_{TV} \leq \| X_0 X_1^* \|_{TV} + \| X_1 X_0^* \|_{TV}
\]

(by the triangle inequality)

\[
\leq \| X_0 \|_F \| X_1^* \|_F + \| X_1 \|_F \| X_0^* \|_F
\]

(by Hölder’s Inequality)

\[
= 2 \| X_0 \|_F \| X_1 \|_F
\]

Hölder’s inequality applies here because the trace norm is the Schatten 1-norm and the Frobenius norm is the Schatten 2-norm. We upper-bound this final expression by noting the following two facts:

\[
\| X_0 \|_F^2 + \| X_1 \|_F^2 = \sum_{x \in \{0,1\}^n} |\langle x | \delta \rangle|^2 \left( \| \Pi_{f(x)} | \psi_x^T \rangle \|_F^2 + \| I - \Pi_{f(x)} | \psi_x^T \rangle \|_F^2 \right) = \| \delta \|_2^2 = 1
\]

\[
\| X_0 \|_F^2 = \sum_{x \in \{0,1\}^n} |\langle x | \delta \rangle|^2 \| \Pi_{f(x)} | \psi_x^T \rangle \|_F^2 \geq \frac{2}{3} \| \delta \|_2^2 = \frac{2}{3}
\]

Therefore, \( 2 \| X_0 \|_F \| X_1 \|_F \) is maximized at \( 2 \sqrt{2/3} \sqrt{1/3} = \frac{2}{3} \sqrt{2} \).

From the first two claims, we know that \( M^{(0)} - M^{(T)} \geq (1 - \frac{2}{3} \sqrt{2} ) \| \Gamma \| \). The last step in the proof is to give an upper bound on \( M^{(t)} - M^{(t+1)} \) for all \( t \).

Claim 3.5. \( M^{(t)} - M^{(t+1)} \leq 2 \max_i \| \Gamma \circ D_i \| \)

Proof. To help us prove this claim, we will define a new density matrix \( W^{(t)}_i \) that is similar to \( W^{(t)} \). Whereas \( W^{(t)} \) is indexed by the basis states of the input qubits \( I \) and has entries defined by the state of the query qubits \( Q \) and the workspace qubits \( W \), \( W^{(t)}_i \) will be indexed by \( I \) and \( Q \) and have entries defined by the state of \( W \).

\[
\langle x, i | W^{(t)}_i | y, j \rangle = \langle x | \delta \rangle \langle \delta | y \rangle \langle \psi_y^T \rangle \langle j | \psi_x^F \rangle
\]

Here, \( i \) and \( j \) are basis states of \( Q \). Note that \( W^{(t)}_i \) is a density matrix since it has trace one, and is positive semi-definite since \( W^{(t)}_i \) is also a Gram matrix.

Let \( G \) and \( D \) be the following block-diagonal \((n \cdot 2^n) \times (n \cdot 2^n)\) matrices:

\[
G = \Gamma \otimes I_n, \quad D = \sum_{i=1}^n D_i \otimes |i \rangle \langle i |
\]
Note that $M^{(t)} = \langle \Gamma, W^{(t)} \rangle = \langle G, W^*_0 \rangle$. We would like to give $M^{(t+1)}$ in terms of $W^*_0$ as well, and so we analyze the effect of a single step of the quantum query algorithm on this matrix. Since the unitary $U_{t+1}$ does not depend on the input qubits, we can ignore it for the purposes of our progress measure: $\langle \psi_x^t | U_{t+1}^* U_{t+1} | \psi_x^t \rangle = \langle \psi_x^t | \psi_x^t \rangle$, and so $W^{(t)}$ does not change after the application of the unitary. This means that $M^{(t+1)} = \langle G, W^*_0 \rangle = \langle G, V_{\text{IND}} W^*_0 V_{\text{IND}} \rangle$.

$$M^{(t)} - M^{(t+1)} = \langle G, W^*_0 \rangle - \langle G, V_{\text{IND}} W^*_0 V_{\text{IND}} \rangle = \langle G, W^*_0 - V_{\text{IND}} W^*_0 V_{\text{IND}} \rangle = \langle G, (W^*_0 - V_{\text{IND}} W^*_0 V_{\text{IND}}) \circ D \rangle$$

This last equality is true because $\langle x, y | (W^*_0 - V_{\text{IND}} W^*_0 V_{\text{IND}}) | y, i \rangle = (1 - (-1)^{x_i+y_i}) \langle x, y | W^*_0 | y, i \rangle$ (which is 0 when $x_i = y_i$) and $G$ is block-diagonal ($\langle x, y | G | y, j \rangle = 0$ if $i \neq j$).

$$M^{(t)} - M^{(t+1)} = \langle G, (W^*_0 - V_{\text{IND}} W^*_0 V_{\text{IND}}) \circ D \rangle$$

$$= \langle G \circ D, (W^*_0 - V_{\text{IND}} W^*_0 V_{\text{IND}}) \rangle$$

$$\leq \|G \circ D\| \cdot \left\| W^*_0 - V_{\text{IND}} W^*_0 V_{\text{IND}} \right\|_\text{Tr}$$

(by the definition of the trace norm)

$$\leq \|G \circ D\| \cdot \left( \left\| W^*_0 \right\|_\text{Tr} + \left\| V_{\text{IND}} W^*_0 V_{\text{IND}} \right\|_\text{Tr} \right)$$

(by the triangle inequality)

$$= 2 \|G \circ D\| \left\| W^*_0 \right\|_\text{Tr}$$

(by the triangle inequality)

$$= 2 \max_i \|\Gamma \circ D_i\|$$

In the above we used the following facts: the trace norm is invariant under conjugation with a unitary, the trace norm of a density matrix is one, and the spectral norm of a block-diagonal matrix is the maximum of the spectral norms of the blocks.

Putting it all together, we have that a quantum query algorithm for $f$ requires at least $\frac{1 - \frac{\sqrt{2}}{2}}{2} \text{Adv}^\pm f = \Omega(\text{Adv}^\pm f)$ rounds.

### 3.2 Adv^\pm is a Lower Bound for the Square Root of Formula Size

The lower bound on $\sqrt{\mathcal{L}(f)}$ using $\text{Adv}^\pm(f)$ makes use of the Karchmer-Wigderson game on $f$.

**Definition 3.6 ([KW90]).** Given a Boolean function $f$, the Karchmer-Wigderson game on $f$ ($\text{KW}(f)$) is a two-player communication game in which one party receives an input $x \in f^{-1}(0)$, one party receives an input $y \in f^{-1}(1)$, and the parties must collectively determine some coordinate $i$ on which $x_i \neq y_i$.

A useful fact is that the minimum number of leaves in a De Morgan formula that computes a function $f$ – denoted $\mathcal{L}(f)$ – is exactly the minimum number of leaves in a communication protocol that successfully solves $\text{KW}(f)$ – denoted $C^P(\text{KW}(f))$.

**Theorem 3.7 ([KW90]).** $\mathcal{L}(f) = C^P(\text{KW}(f))$

We give a brief sketch of the proof, noting that we only need one direction for the lower bound in this section.

**Proof (Sketch).** Given a formula for $f$, we can use induction on the depth of the formula to produce a communication protocol for $\text{KW}(f)$.

If the formula is a single leaf, then that leaf must be labelled with some literal. Then, since the formula evaluates to false on $x$ and true on $y$, the players know that they differ on the leaf’s literal and therefore no communication is required (and so the communication protocol for $\text{KW}(f)$ is also a single leaf).
If the formula is the logical AND of two subformulae, then $y$ must evaluate to 1 on both subformulae but $x$ must evaluate to 0 on at least one, so the player holding $x$ can report which. The parties continue with the protocol for that subformula, so the number of leaves in the communication protocol is (by induction) the sum of the number of leaves in the subformulae, which is just the number of leaves in the entire formula. A similar situation holds when the formula is the logical OR of two subformulae, but with the player holding $y$ speaking.

A communication protocol for $KW(f)$ can be used to construct a formula for $f$ in an analogous fashion. □

A communication protocol for $KW(f)$ partitions $f^{-1}(0) \times f^{-1}(1)$ into $C^P(KW(f))$ combinatorial rectangles, where each rectangle is monochromatic in terms of $KW(f)$: that is, each rectangle is associated with some $i$ where $x_i \neq y_i$ for all $(x, y)$ in the rectangle. Let $C^D(KW(f))$ be the minimum number of monochromatic combinatorial rectangles required to partition $f^{-1}(0) \times f^{-1}(1)$. Clearly, $C^D(KW(f)) \leq C^P(KW(f))$.

In order to prove Theorem 3.2, we will exploit two properties of the spectral norm. The first is that the spectral norm (indeed, any matrix norm) is monotone with respect to submatrices: if $A$ is a submatrix of $B$, then $\|A\| \leq \|B\|$. The second is that the square of the spectral norm is subadditive over rectangles. For a $|X| \times |Y|$ matrix $A$ and a combinatorial rectangle $R \subseteq X \times Y$, let $A_R$ be defined by:

$$\langle x|A_R|y \rangle = \begin{cases} \langle x|A|y \rangle & (x, y) \in R \\ 0 & \text{otherwise} \end{cases}$$

Lemma 3.8 ([LLS06]). If $A$ is an $|X| \times |Y|$ matrix and $R$ partitions $X \times Y$ into combinatorial rectangles, then $\|A\|^2 \leq \sum_{R \in \mathcal{R}} \|A_R\|^2$.

Proof. Note that $\|A\| = \max_{u,v} |\langle u|A|v \rangle|/\|u\| \|v\|$. In the following, let $|u|$ and $|v|$ be the unit vectors that achieve the maximum in this expression.

For any $R \in \mathcal{R}$ where $R = X_R \times Y_R$ for $X_R \subseteq X, Y_R \subseteq Y$, define $|u_R\rangle$ and $|v_R\rangle$ as follows:

$$\langle u_R|x \rangle = \begin{cases} \langle u|x \rangle & x \in X_R \\ 0 & \text{otherwise} \end{cases} \quad \langle v_R|y \rangle = \begin{cases} \langle v|y \rangle & y \in Y_R \\ 0 & \text{otherwise} \end{cases}$$

$$\|A\| = |\langle u|A|v \rangle| = \left| \langle u \bigg| \sum_{R \in \mathcal{R}} A_R \bigg| v \rangle \right| = \sum_{R \in \mathcal{R}} \langle u|A_R|v \rangle = \sum_{R \in \mathcal{R}} \langle u_R|A_R|v_R \rangle \leq \sum_{R \in \mathcal{R}} |\langle u_R|A_R|v_R \rangle| \leq \sum_{R \in \mathcal{R}} \|A_R\| \|u_R\| \|v_R\|$$

$$\leq \left( \sum_{R \in \mathcal{R}} \|A_R\|^2 \right)^{1/2} \left( \sum_{R \in \mathcal{R}} |u_R|^2 \|v_R\|^2 \right)^{1/2}$$

(by the Cauchy-Schwarz inequality)

Note that the second term here simplifies:

$$\sum_{R \in \mathcal{R}} |u_R|^2 \|v_R\|^2 = \sum_{R \in \mathcal{R}} \sum_{(x,y) \in R} \langle u|x \rangle \langle v|y \rangle = \|u\|^2 \|v\|^2$$

(as $\mathcal{R}$ partitions $X \times Y$)

To conclude, note that as $|u|$ and $|v|$ are unit vectors, $\|u\|^2 \|v\|^2 = 1$: therefore, $\|A\| \leq \left( \sum_{R \in \mathcal{R}} \|A_R\|^2 \right)^{1/2}$ and so $\|A\|^2 \leq \sum_{R \in \mathcal{R}} \|A_R\|^2$. □
Now we can prove Theorem 3.2.

Proof of Theorem 3.2. Let $A$ be any $f^{-1}(0) \times f^{-1}(1)$ matrix. Let $\mathcal{R}_f$ be an optimal rectangle partition in terms of $KW(f)$.

$$\|A\|^2 \leq \sum_{R \in \mathcal{R}_f} \|A_R\|^2 \leq C^D(KW(f)) \cdot \max_{R \in \mathcal{R}_f} \|A_R\|^2$$

Let $A_i$ be the $f^{-1}(0) \times f^{-1}(1)$ matrix defined by:

$$\langle x | A_i | y \rangle = \left\{ \begin{array}{ll} \langle x | A | y \rangle & x_i \neq y_i \\ 0 & \text{otherwise} \end{array} \right.$$ 

Then, for any $R$, $A_R$ is a submatrix of $A_i$, so by the monotonicity with respect to rectangles:

$$C^D(KW(f)) \cdot \max_{R \in \mathcal{R}_f} \|A_R\|^2 \leq C^D(KW(f)) \cdot \max_{i \in [n]} \|A_i\|^2$$

Rearranging, we get:

$$\mathcal{L}(f) \geq C^D(KW(f)) \geq \max_{A \neq 0} \frac{\|A\|^2}{\max_i \|A_i\|^2}$$

We conclude by taking the square root of the above expression and noting that for any matrix $A \in f^{-1}(0) \times f^{-1}(1)$, letting $A'$ be the matrix of the form $A' = \begin{bmatrix} 0 & A \\ A^* & 0 \end{bmatrix}$, we have that $A'$ is an adversary matrix for $f$ and $\|A'\| = \|A\|$, so maximizing over matrices $A$ on the right-hand side is equivalent to maximizing over adversary matrices $A'$.

\[\square\]

4 Span Programs

Given a function $f$, its span program $P_f$ is an algebraic model of computation for $f$ first introduced by Karchmer and Wigderson. Let $A$ be a matrix whose columns are labelled by the set of $2n$ literals. Let $|t|$ be a target vector. For input $s$ such that $f(s) = 1$, we would like the target vector $|t|$ to be contained in the span of the columns of $A$ that are labelled by literals that agree with $s$. Otherwise, if $f(s) = 0$, we require that $|t|$ is not in the span. In this case, there must exist some vector $|y|$ that witnesses this fact (as shown by Farkas’ Lemma). More formally, we define the span program as follows.

Definition 4.1. (Span Programs, [KW93].) A span program $P_f$ for an $n$-ary boolean function $f$ consists of a matrix $A \in \mathbb{L}(\mathbb{C}^l, \mathbb{C}^m)$ and a target vector $|t| \in \mathbb{C}^m$, where $I$ is the disjoint union of $2n$ index sets $I_{1,0}, I_{1,1}, \ldots, I_{n,0}, I_{n,1}$ one for each setting of each entry of a boolean string $s \in \{0,1\}^n$. Given $s$, $\Pi(s) \in \mathbb{L}(\{0,1\}^I)$ is the diagonal matrix whose diagonal entry $(j,b) \times (j,b)$ indicates $s_j = b$ i.e.

$$\Pi(s) = \mathbb{I} - \sum_{j \in [n]} |j, \bar{s}_j\rangle \langle j, \bar{s}_j|.$$

The span program $P_f$ evaluates to false if there exists a negative witness $|y| \in \mathbb{C}^m$ i.e. $\langle y | A \Pi(s) | 0 \rangle = 0$ but $\langle y | t \rangle > 0$; wlog. assume that $\langle y | t \rangle = 1$ by scaling. Conversely, $P_f$ evaluates to true if there exists a positive witness $|z| \in \mathbb{C}^l$ i.e. $|t|$ is in the span of $A \Pi(s)$ and $A \Pi(s) | z \rangle = |t\rangle$.

For inputs which evaluate to true on $P_f$, i.e. $x \in F_1$ for which there exists $|z\rangle$ such that $A \Pi(x) | z\rangle = |t\rangle$, let $\text{wsize}(P_f, x) = \| |z\rangle \|^2$. For inputs which evaluate to false on $P_f$, i.e. $w \in F_0$ for which there exists $|y\rangle$ such that $\langle y | A \Pi(w) = 0$ and $\langle y | t \rangle = 1$, let $\text{wsize}(P_f, w) = \| |y\rangle |A\|^2$.

The witness size of $P_f$ is then

$$\text{wsize}(P_f) = \max_{s \in \{0,1\}^n} \text{wsize}(P_f, s).$$

\[\text{Note that this value is equivalent to } \| (z | A (\mathbb{I} - \Pi(s))) \| \text{ by the first condition.}\]
Using SDP duality, we show that the witness size of the span-program of \( f \) is equivalent to its general adversary bound.

**Example 4.2.** Consider the span programs for several simple functions. Note that there can be many different span programs for the same function. All omitted column index sets are assumed to be empty.

1. For the \( n \)-ary logical or function, \( \text{OR}_n \), let \( |t| = [1] \) and
   \[
   A = \begin{bmatrix}
   I_{1,1} & I_{2,1} & \cdots & I_{n-1,1} & I_{n,1} \\
   1 & 1 & \cdots & 1 & 1
   \end{bmatrix}
   \]

   Observe that \( \text{ws} = \text{size}(P_{\text{OR}_n}) = \max_{s \in \{0,1\}^n} \text{ws}(P_{\text{OR}_n}, s) = n^2 \) is achieved by the input string \( s = [0, \ldots, 0]^T \) with the witness \( |y| = [1] \).

2. For the parity function \( \oplus_2 \), let \( |t| = [1, 1]^T \) and
   \[
   A = \begin{bmatrix}
   I_{1,0} & I_{1,1} & I_{2,0} & I_{2,1} \\
   1 & 0 & 1 & 0 \\
   0 & 1 & 0 & 1
   \end{bmatrix}
   \]

   Observe that \( \text{ws} = \text{size}(P_{\oplus_2}) = 2. \) This can be achieved by a string which evaluates to false e.g. \( w = 00 \) with witness \( |y| = [0, 1]^T \) and \( \text{ws} = \text{size}(P_{\oplus_2}, w) = ||y||^2 \) or by a string which evaluates to true e.g. \( x = 01 \) with witness \( |z| = [1, 1]^T \) and \( \text{ws} = \text{size}(P_{\oplus_2}, w) = ||z||^2 \).

### 4.1 Canonical Span Programs

In order to relate the complexity of the span program of a given function \( f \) to its query complexity, we put it in *canonical span program* form. Every span program can be transformed into a canonical span program with at most a polynomial blow-up in size [KW93].

**Definition 4.3.** (Canonical Span Program.) The input matrix \( A \) and target vector \( |t| \) of the canonical span program will be as follows. Define \( |t| \in \mathbb{C}^{F_0} \) to be a scalar multiple of the all ones vector. Let \( A \in \mathcal{L}(\mathbb{C}^I, \mathbb{C}^{F_0}) \) where \( I = [m] \times \{0, 1\}^m \) for a yet-to-be-determined \( m \). Each row of \( A \) corresponds to an input \( w \) evaluating to zero on \( f \). Divide this row further into \( 2n \) row vectors of length \( m \) for each setting of each entry in the input. In the following, if \( w_j = b \), then denote each length-\( m \) vector corresponding to \( I_{j,b}(w) \) by \( |v_{w,j}^b\rangle \) and corresponding to \( I_{j \bar{b}} \) by \( |v_{w,j}\rangle \).

Define \( |v_{w,j}^0\rangle \) to be the all zeroes vector for all \( w \in F_0 \) and \( j \in [m] \). Observe that \( |t| \) cannot be in the span of \( \text{All}(w) \) since the row of \( \text{All}(w) \) corresponding to \( w \) consists entirely of zeros. Further, since the indicator vector \( |w\rangle \in \mathbb{C}^{F_0} \) for \( w \) is a witness for \( A \),

\[
\text{ws}(P_f, w) = \| \langle w | A \rangle \|^2 = \sum_{j \in [n]} \| v_{w,j} \|^2.
\]

Each \( x \in F_1 \) will assign an input vector of length \( mn \). These will not appear in \( A \), but will be used to ensure that the vectors \( |v_{w,j}\rangle \) in \( A \) satisfy certain constraints. Each vector will be divided into \( n \) length \( m \) vectors corresponding to the \( n \) entries of \( x \). These will be denoted by \( |v_{x,j}\rangle \). Since \( |t| \) needs to be in the span of \( \text{All}(x) \), we require that for all \( w \in F_0 \), \( \sum_{w_j \neq x_j} \langle v_{w,j} | v_{x,j}\rangle = 1 \). Observe that the witness size is again of the form

\[
\text{ws}(P_f, x) = \sum_{j \in [n]} \| v_{x,j} \|^2.
\]

\(^4\)Since \( \langle w | t \rangle = 1 \) while \( \langle w | \text{All} \rangle = 0 \).
The smallest $m$ for which there exists such vectors $|v_{w,j}\rangle$ and $|v_{x,j}\rangle$ will suffice.

In the following let $W$ be the witness size of the canonical span program.

**Example 4.4.** The canonical span program for $\otimes_2$ is as follows. Let the target vector be $|t\rangle = c[1,1]^T$ where $c = 1/(3\sqrt{W})$. Then for $\{w_1 = 00, w_2 = 11\} = F_0$ with vector $|v_{w,j}\rangle \in \mathbb{C}^m$ corresponding to the length $m$ vector of the $j^{th}$ bit of $w_i$, we have

$$A = \begin{bmatrix}
I_{1,0} & I_{1,1} & I_{2,0} & I_{2,1} \\
0 & \langle v_{w,1} | & 0 & \langle v_{w,2} | \\
\langle v_{w,2} | & 0 & \langle v_{w,1} | & 0 \\
\end{bmatrix} \begin{array}{c}
w_1 = 00 \\
w_2 = 11
\end{array}$$

Further, to each string $x_i$ in $\{x_1 = 10, x_2 = 01\} = F_1$ we assign a vector $|x_i\rangle = [v_{x,i,1}, v_{x,i,2}]^T$ where $|v_{x,i,j}\rangle \in \mathbb{C}^m$ corresponds to the length $m$ vector of the $j^{th}$ bit of $x_i$. Note that $m = 1$ suffices, since the matrix $A$ where

$$A = \begin{bmatrix}
I_{1,0} & I_{1,1} & I_{2,0} & I_{2,1} \\
0 & 1 & 0 & 1 \\
1 & 0 & 1 & 0
\end{bmatrix} \begin{array}{c}
w^{(1)} = 00 \\
w^{(2)} = 11
\end{array}$$

and the pair of vectors $|x_1\rangle = |x_2\rangle = [1,1]^T$ satisfies the condition $\sum_{w \neq x} |v_{w,j}|v_{x,j} = 1$.

### 4.2 The Dual of Adv is Span Program Witness Size

From the canonical span program above we write the witness size as the following optimization problem:

$$\text{wsize}(P_f) = \min_{\{\{v_{w,j}\}\} s \in \{0,1\}^n, j \in [n]} \max_{|v_{x,j}\rangle} \|v_{x,j}\|^2$$

subject to the constraint that for all pairs $(w, x) \in F_0 \times F_1$, $\sum_{w \neq x} \langle v_{w,j} | v_{x,j} \rangle = 1$. Let $X$ be PSD matrix such that entry $\langle w, i | X | x, j \rangle = \langle v_{w,i} | v_{x,j} \rangle$ for all $w \in F_0$ and $x \in F_1$. Write $\text{wsize}(P_f)$ as the following equivalent SDP

$$\text{wsize}(P_f) = \min_{X \succeq 0} \max_{s \in \{0,1\}^n} \sum_{j \in [n]} \langle s, j | X | s, j \rangle$$

subject to the constraint that for all $(x, w) \in F_0 \times F_1$, $\sum_{w \neq x} \langle w, j | X | x, j \rangle = 1$.

We will turn the above SDP into the general adversarial bound. First introduce a variable $\xi$ in order to
eliminate the inner maximization function. For adversary matrix \( \Gamma \) let \( \Gamma_j = \Gamma \circ D_j \).

\[
\text{ws}(P_f) = \min_{\xi} \xi \quad \text{subject to} \quad \forall (w,x) \in F_0 \times F_1: \sum_{x,y} \alpha_{w,x} \langle w, y \rangle \text{subject to} \quad \forall s \in \{0,1\}^n: \xi \geq \sum_{s \in \{0,1\}^n} \langle s, y \rangle \text{subject to} \quad \forall (w,x) \in F_0 \times F_1: \sum_{x,y} \alpha_{y,x} |w \rangle |x\rangle
\]

\[
= \max_{\{\alpha_{w,x}\}, \beta_x \geq 0, \sum_x \beta_x = 1, \sum_x \beta_x |s\rangle \langle s| \geq \sum_{w,x,y} \alpha_{w,x} |w \rangle |x\rangle}
\]

\[
= \max_{\{\alpha_{w,x}\}, \beta_x \geq 0, \sum_x \beta_x = 1, \sum_x \beta_x |s\rangle \langle s| \geq \sum_{w,x,y} \alpha_{w,x} |w \rangle |x\rangle}
\]

\[= \max_{\{\alpha_{w,x}\}, \beta_x \geq 0, \sum_x \beta_x = 1, \sum_x \beta_x |s\rangle \langle s| \geq \sum_{w,x,y} \alpha_{w,x} |w \rangle |x\rangle} \sum \alpha_{w,x} \quad \text{(substitute } |s'\rangle = \frac{1}{\sqrt{\beta_s}} |s\rangle )
\]

\[= \max_{\{\alpha_{w,x}\}, \beta_x \geq 0, \sum_x \beta_x = 1, \sum_x \beta_x |s\rangle \langle s| \geq \sum_{w,x,y} \alpha_{w,x} |w \rangle |x\rangle} \sum \alpha_{w,x} \beta_x \quad \text{(substitute } \alpha_{w,x}' = \alpha_{w,x}/\sqrt{\beta_w})
\]

\[= \max_{\{\beta\} |\beta\rangle \langle \beta| \geq 0, \sum_x |\beta_s\rangle \langle \beta_s| \leq 1} \langle \beta| \Gamma |\beta\rangle \quad \text{(substitute } \langle \beta| \Gamma |\beta\rangle = 1 \text{ if } w_j = x_j )
\]

\[= \max_{\{\beta\}} |\beta\rangle \langle \beta| \leq 1}
\]

\[= \text{Adv}(f)
\]

\[B_{G(s)} = \begin{bmatrix} \mu_0 & I \\ 0 & \Pi_s \end{bmatrix} F_0 \quad B_{G'(s)} = \begin{bmatrix} I \\ \Pi_s \end{bmatrix} F_0 \]

\[|t\rangle = \frac{1}{3\sqrt{W}} \sum_{w \in F_0} |w\rangle \quad \text{and} \quad A = \sum_{w \in F_0, j \in [n]} |w\rangle \langle j| \otimes |v_{w,j}\rangle
\]

\[\text{where } W \text{ is the witness size and } \Pi_s = 1 - \Pi_s \in \mathcal{L}(\mathcal{C}^I) \text{ (see } \Pi(s) \text{ in Equation 1).}
\]

4.3 Span Programs as Graphs

The canonical span program matrix \( A \) of \( f \) can be transformed into the biadjacency matrix of two bipartite graphs [Rei10; Rei11; RS12]. These graphs capture the evaluation of a string \( s \) on \( f \): in particular, we define a “true” biadjacency matrix such that if \( f(s) = 1 \) then there is an eigenvalue-zero eigenvector while no such eigenvector exists when \( f(s) = 0 \), and a “false” biadjacency matrix where the opposite is true. Let \( B_{G(s)} \in \mathbb{C}^{(F_0 \cup F_1) \times \{0,1\}\cup I} \) and \( B_{G'(s)} \in \mathbb{C}^{(F_0 \cup F_1) \times I} \) be the true and false biadjacency matrices corresponding to the bipartite graph \( G \) of the span program respectively:

\[B_{G(s)} = \begin{bmatrix} \mu_0 & I \\ 0 & \Pi(s) \end{bmatrix} F_0 \quad B_{G'(s)} = \begin{bmatrix} I \\ \Pi(s) \end{bmatrix} F_0 \]

\[|t\rangle = \frac{1}{3\sqrt{W}} \sum_{w \in F_0} |w\rangle \quad \text{and} \quad A = \sum_{w \in F_0, j \in [n]} |w\rangle \langle j| \otimes |v_{w,j}\rangle
\]

where \( W \) is the witness size and \( \Pi(s) = 1 - \Pi(s) \in \mathcal{L}(\mathcal{C}^I) \) (see \( \Pi(s) \) in Equation 1).
Example 4.5. Let us turn the canonical span program of the parity function, shown in Example 4.4, into its corresponding bipartite graphs. The matrices $B_{G(x)}$ and $B_{G'(w)}$ are then defined as follows for strings $x = 10$ and $w = 00$ which evaluates to true and false respectively.

$$B_{G(x)} = \begin{bmatrix} \mu_0 & I \\ 1 & 0 & 1 & 0 \\ 1 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix} \quad F_0 = \begin{bmatrix} F_0 & I' \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix} I'$$

These corresponds to the bipartite graphs shown Figure 1 and Figure 2.

These corresponds to the bipartite graphs shown Figure 1 and Figure 2.

Figure 1: The bipartite graphs corresponding to the true biadjacency matrix. All unmarked edges have weight one. The matrix vector product $B_{G(x)} |\phi\rangle$ is equivalent to assigning weights to the open dots in the picture. In order to find an eigenvalue zero eigenvector $|\phi\rangle$ of $B_{G(x)}$, the assignment of weights must ensure the neighbours of every solid dot sums to zero. Observe that $B_{G(x)}$, with $\oplus(x) = 1$, has an eigenvalue zero eigenvector while $B_{G'(w)}$, with $\oplus(w) = 0$, does not.

Figure 2: The bipartite graphs corresponding to the false biadjacency matrix. As opposed to the above, $B_{G'(x)}$, with $\oplus(x) = 1$, does not have an eigenvalue zero eigenvector while $B_{G'(w)}$, with $\oplus(w) = 0$, does.

Lemma 4.6. (Spectral Gap of Eigenvalue Zero Eigenvectors.) If $f(x) = 1$, then the vector

$$|\psi\rangle = |\psi_1\rangle + |\psi_2\rangle \quad \text{where} \quad |\psi_1\rangle = -3\sqrt{W} |0\rangle \quad \text{and} \quad |\psi_2\rangle = \sum_{j \in [n]} |j, x_j\rangle \otimes |v_{x,j}\rangle$$

is an eigenvalue zero eigenvector of $B_{G(x)}$. Further, $|\psi\rangle$ satisfies $|\langle 0 | \psi \rangle|^2 \geq 9 \|\psi\|^2 / 10$.

If instead $f(w) = 0$, then the vector

$$|\psi'\rangle = |\psi'_1\rangle + |\psi'_2\rangle \quad \text{where} \quad |\psi'_1\rangle = -|w\rangle \quad \text{and} \quad |\psi'_2\rangle = \sum_{j \in [n]} |j, w_j\rangle \otimes |v_{w,j}\rangle$$
is an eigenvalue zero eigenvector of $B_{G'(w)}$. Further, $|\psi'\rangle$ satisfies $|\langle t|\psi'\rangle|^2 \geq \|\psi\|^2/(9W(W + 1))$.

Proof. Let $x \in F_1$ and $w \in F_0$. Observe that $B_{G(x)}|\psi_1\rangle$ is the vector with $|F_0|$ non-zero entries followed by $|I'|$ zeros. Since $f(x) = 1$, there exists a linear combination of the columns of $A$ which sum to $|t\rangle$. Choosing this set of columns will also ensure that the rows indexed by $I'$ sum to zero as an entry of $|\psi_2\rangle$ is non-zero only when the associated column of $\Pi(x)$ is. Further $|\langle 0|\psi\rangle|^2 = \|\psi_1\|^2 = 9W$, while $\|\langle t|\psi\rangle|^2 = \|\psi_1\|^2 + \|\psi_2\|^2 = 9W + W$ by definition. Similarly, observe that $B_{G'(w)}^*|\psi_1\rangle$ multiplies the column associated with $w$ among the rows of $A$ by negative one, while $B_{G'(w)}^*|\psi_2\rangle$ is exactly this same column. Further, $|\langle t|\psi'\rangle|^2 = 1/(9W)$ and $\|\langle t|\psi'\rangle|^2 = \|\psi_1\|^2 + \|\psi_2\|^2 = 1 + W$. \hfill $\Box$

5 Optimal Quantum Query Algorithms for Span Programs

Let $|t\rangle$ and $A$, as shown in Equation 9, be the target and matrix of the canonical span program respectively. Further let $G$ be the associated bipartite graph with biadjacency matrix $B_G$ and adjacency matrix $A_G$ as follows

$$B_G = \begin{bmatrix} \mu_0 & I \\ |t\rangle & A \end{bmatrix} \quad \text{and} \quad A_G = \begin{bmatrix} F_0 & \mu_0 & I \\ |t\rangle & 0 & 0 \\ A^* & 0 & 0 \end{bmatrix}$$ (10)

Let $\Delta \in \mathbb{L}(\mathbb{C}^{F_0\cup\{\mu_0\}\cup I})$ be the orthogonal projection onto the span of all eigenvalue zero eigenvectors of $A_G$. For a string $s \in \{0, 1\}^n$, let $\Pi_s \in \mathbb{L}(\mathbb{C}^{F_0\cup\{\mu_0\}\cup I})$ be

$$\Pi_s = \mathbb{I} - \sum_{j=[n], k=[m]} |j, \pi_j, k\rangle\langle j, \pi_j, k|.$$  

The graph $G(s)$ has biadjacency matrix $B_{G(s)}$ (from Equation 8) and adjacency matrix $A_{G(s)}$.

$$B_{G(s)} = \begin{bmatrix} \mu_0 & I \\ |t\rangle & \Pi(s) \end{bmatrix} \quad \text{and} \quad A_{G(s)} = \begin{bmatrix} F_0 & I' & \mu_0 & I \\ 0 & 0 & |t\rangle & A \\ 0 & 0 & 0 & \Pi(s) \end{bmatrix}$$ (11)

Note that $A_{G(s)} \in \mathbb{L}(\mathbb{C}^{F_0\cup I'\cup\{\mu_0\}\cup I})$ contains $A_G$ and the additional vertices of $I'$. Further $\mathbb{I} - \Pi_s \in \mathbb{L}(\mathbb{C}^{F_0\cup\{\mu_0\}\cup I})$ contains $\Pi(s) \in \mathbb{L}(\mathbb{C}^I)$ as a subgraph and is everywhere else zeros.

Define $U_s \in \mathbb{L}(\mathbb{C}^{F_0\cup\{\mu_0\}\cup I})$ as $U_s = (2\Pi_s - \mathbb{I})(2\Delta - \mathbb{I})$, the matrix which reflects a vector across $\Delta$ then across $\Pi_s$. Observe that $\Delta$ is independent of the input $s$, while $\Pi_s$ requires one query of the quantum $f$-oracle. The following are three different quantum query
algorithms which compute \( f(s) \) with query complexity \( W \).

**Algorithm 1: Phase Estimation**

- Initialize state \(|0\rangle \in \mathbb{C}^{F_0 \cup \mu_0 \cup I}\)
- \( \delta_p \leftarrow \frac{1}{100W} \)
- \( \delta_e \leftarrow \frac{1}{10} \)
- Run phase estimation on \( U_s \) with precision \( \delta_p \) and error \( \delta_e \)
- Return 1 if phase estimation returns zero, otherwise return 0

**Algorithm 2: Quantum Search**

- Initialize state \(|+\rangle \otimes |0\rangle \in \mathbb{C}^2 \otimes \mathbb{C}^{F_0 \cup \mu_0 \cup I}\)
- \( T \leftarrow \) random integer in \{1,...,\lceil 100W \rceil\}
- Apply \(|0\rangle\langle 0| \otimes I + |1\rangle\langle 1| \otimes U_T^T \) to initial state
- Measure the first qubit in the Hadamard basis
- Return 1 if the value is \(|+\rangle\), otherwise return 0

**Algorithm 3: Quantum Search without Register**

- Initialize state \(|0\rangle \in \mathbb{C}^{F_0 \cup \mu_0 \cup I}\)
- \( T \leftarrow \) random integer in \{1,...,\lceil 100W \rceil\}
- Apply \( U_T^T \) to \(|0\rangle\)
- Measure \( U_T^T|0\rangle \) in the standard basis
- Return 1 if the value is \(|0\rangle\), otherwise return 0

We will only analyse the first two algorithms. The analysis for the third Algorithm 3 is quite complex and the quantum query complexity is equivalent to the other two. The following lemma about the “effective spectral” gap of \( A_{G(s)} \) will be necessary for the analysis. Its intuition and proof can be found in Appendix B.

**Lemma 5.1. (Effective Spectral Gap.)** If \( f(s) = 1 \) then \( A_{G(s)} \) has an eigenvalue zero eigenvector \( |\psi\rangle \) with \( |\langle 0|\psi\rangle|^2 \geq 9 \| |\psi\rangle \|^2 / 10 \).

If \( f(w) = 0 \) and \( \{|\alpha\rangle\} \) is the set of all orthonormal eigenvectors with corresponding eigenvalues \( \rho(\alpha) \) of \( A_{G(s)} \), then for any \( c \geq 0 \)

\[
\sum_{\alpha: |\alpha\rangle \in \mathbb{C}^{F_0 \cup \mu_0 \cup I}} |\langle 0|\alpha\rangle|^2 \leq 72c^2 \left(1 + \frac{1}{W}\right).
\]

**5.1 Spectral Gap for \( U_s \)**

Using Lemma 5.1, we prove a spectral gap on the eigenvectors of the matrix \( U_s \).

**Lemma 5.2.** If \( f(s) = 1 \) then \( U_s \) has an eigenvalue one eigenvector \( |\varphi\rangle \) with \( |\langle 0|\varphi\rangle|^2 / ||\varphi||^2 \geq 9/10 \).

If \( f(s) = 0 \) and \( \{|\beta\rangle\} \) is a set of orthonormal eigenvectors of \( U_s \) with corresponding eigenvalues \( e^{i\theta(\beta)} \), where \( \theta(\beta) \in (-\pi, \pi) \). Then for any \( \Theta \geq 0 \)

\[
\sum_{\beta: |\beta\rangle \in \mathbb{C}^{F_0 \cup \mu_0 \cup I}} |\langle 0|\beta\rangle|^2 \leq \left(2\sqrt{6\Theta W} + \frac{\Theta}{2}\right)^2.
\]

A key tool used to prove Lemma 5.2 is the fact that we can rotate the basis of \( U_s \) so that it becomes block-
diagonal with blocks of maximum dimension two\textsuperscript{5}. This was proved by Szegedy [Sze04]. Nagaj, Wocjan, and Zhang [NWZ09] gave a different proof that follows from a Lemma of Jordan [Jor75]:

**Lemma 5.3. ([Jor75])** Given projections $\Pi_s$ and $\Delta$ in Hilbert space $\mathcal{H}$, there exists a decomposition of $\mathcal{H}$ into orthogonal one-dimensional and two-dimensional subspaces invariant under $\Pi_s$ and $\Delta$. On the two-dimensional subspaces, $\Pi_s$ and $\Delta$ are rank-one projectors.

Lemma 5.3 implies that $\mathcal{H}$ can be decomposed into a set of one-dimensional subspaces $\{T_i\}$ and a set of two-dimensional subspaces $\{S_i\}$. Each one-dimensional subspace $T_i$ is spanned by a vector $|v_i\rangle$ for which there exists $b, c \in \{0, 1\}$ such that $\Delta|v_i\rangle = b|v_i\rangle$ and $\Pi_s|v_i\rangle = c|v_i\rangle$: that is, each of $\Delta$ and $\Pi_s$ either act as the identity on $T_i$ or are orthogonal to $T_i$. Each two-dimensional subspace $S_i$ is spanned by vectors $|v_i\rangle, |v_i^+\rangle$ such that $\Delta|v_i\rangle = |v_i\rangle$ and $\Delta|v_i^+\rangle = 0$. Also, $S_i$ is spanned by vectors $|w_i\rangle, |w_i^+\rangle$ such that $\Pi_s|w_i\rangle = |w_i\rangle$ and $\Pi_s|w_i^+\rangle = 0$. Let $\theta_i = 2 \arccos(|v_i|)$. Then,

$$|w_i\rangle = \cos \left(\frac{\theta_i}{2}\right)|v_i\rangle + \sin \left(\frac{\theta_i}{2}\right)|v_i^+\rangle \quad |w_i^+\rangle = -\sin \left(\frac{\theta_i}{2}\right)|v_i\rangle + \cos \left(\frac{\theta_i}{2}\right)|v_i^+\rangle$$

**Theorem 5.4. ([Sze04; NWZ09])** Let $\{S_i\}, \{T_i\}$ be the decomposition of $\Pi_s$ and $\Delta$ given by Lemma 5.3. Then $U_s$ has eigenvalues $e^{\mp i\theta}$, corresponding to $\{|v_i\rangle, |v_i^\perp\rangle\}$ on each two-dimensional subspace $S_i$, and eigenvalue either 1 or -1 on each one-dimensional subspace $T_i$.

**Proof.** On one-dimensional subspace $T_i$, each individual reflection multiplies a vector by $\pm 1$, so both reflections in succession do as well. For the rest of the proof, consider a two-dimensional subspace $S_i$. By the above relationship between $\{|v_i\rangle, |v_i^\perp\rangle\}$ and $\{|w_i\rangle, |w_i^\perp\rangle\}$, we get the following:

$$\begin{bmatrix} |w_i\rangle \\ |w_i^\perp\rangle \end{bmatrix} = \begin{bmatrix} \cos \frac{\theta_i}{2} & \sin \frac{\theta_i}{2} \\ -\sin \frac{\theta_i}{2} & \cos \frac{\theta_i}{2} \end{bmatrix} \begin{bmatrix} |v_i\rangle \\ |v_i^\perp\rangle \end{bmatrix}$$

Recall that $\sigma_y = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}$ is the Pauli Y matrix, which has eigenvalues 1 and -1 corresponding to eigenvectors $|\phi_y^+\rangle = \frac{1}{\sqrt{2}}|1\rangle$ and $|\phi_y^-\rangle = \frac{1}{\sqrt{2}}|1\rangle$, respectively.

$$\begin{bmatrix} \cos \frac{\theta_i}{2} & \sin \frac{\theta_i}{2} \\ -\sin \frac{\theta_i}{2} & \cos \frac{\theta_i}{2} \end{bmatrix} = \cos \left(\frac{\theta_i}{2}\right) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} + i \sin \left(\frac{\theta_i}{2}\right) \begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix}$$

$$= \frac{e^{i\theta_i}}{2} \begin{bmatrix} 1 & -i \\ i & 1 \end{bmatrix} + \frac{e^{-i\theta_i}}{2} \begin{bmatrix} 1 & i \\ -i & 1 \end{bmatrix}$$

$$= e^{-i\theta_i/2} \frac{e^{i\theta_i/2}}{\sqrt{2}} |\phi_y^+\rangle + e^{-i\theta_i/2} |\phi_y^-\rangle = e^{i\theta_i/2} |\phi_y^+\rangle + e^{-i\theta_i/2} |\phi_y^-\rangle$$

In the basis $\{|v_i\rangle, |v_i^\perp\rangle\}$, we have that $(2\Delta - \mathbb{I}) = \begin{bmatrix} 2 & 0 \\ 0 & -2 \end{bmatrix}$, $|\sigma_z\rangle = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$, and $|\sigma_z\rangle = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$, where $\sigma_z$ is the Pauli Z matrix. Similarly, in the basis $\{|w_i\rangle, |w_i^\perp\rangle\}$, $U_s = (2\Pi(s) - \mathbb{I})(2\Delta - \mathbb{I}) = e^{-(i\theta_i/2)|\sigma_y\rangle e^{(i\theta_i/2)|\sigma_z\rangle}} = e^{-(i\theta_i/2)|\sigma_y\rangle e^{(i\theta_i/2)}|\sigma_z\rangle} = e^{-(i\theta_i/2)|\sigma_y\rangle e^{(i\theta_i/2)}|\sigma_z\rangle} = e^{-(i\theta_i/2)|\sigma_y\rangle}$, where we used the fact that $\sigma_y$ and $\sigma_z$ anticommute ($\sigma_y\sigma_z = -\sigma_z\sigma_y$) and the fact that $\sigma_z\sigma_z = \mathbb{I}$. Therefore, the eigenvalues are $e^{-i\theta_i}$ and $e^{i\theta_i}$, corresponding to eigenvectors $|\phi_y^+\rangle = \frac{|v_i\rangle + i|v_i^\perp\rangle}{\sqrt{2}}$ and $|\phi_y^-\rangle = \frac{|v_i\rangle - i|v_i^\perp\rangle}{\sqrt{2}}$, respectively.

\[\square\]

Now we can prove Lemma 5.2.

\textsuperscript{5}We can do this for any unitary made up of two reflections
Proof of Lemma 5.2. Let \{|β⟩\} be the set of eigenvectors given by the decomposition of Theorem 5.4. Since \(Δ\) is the projection into the nullspace of \(A_G\), \(A_GΔ = 0\). Thus \(A_{G(s)}(Δ ⊕ 1) = T(I - \Pi_s) ⊕ (\hat{f}_s)\) for a permutation matrix \(T\) since \(G\) is a subgraph of \(A_{G(s)}\) and \(Π(s)\) is a submatrix of \(I - \Pi_s\) from Equation 10 and Equation 11.

First consider the case where \(f(s) = 1\). Take \(|ψ⟩\) to be the eigenvalue zero eigenvector of \(A_{G(s)}\) such that \(|0⟨ψ|⟩|^2 ≥ 9||ψ||^2/10\) from Lemma 5.1. Obtain \(|φ⟩\) from \(|ψ⟩\) by restricting to the entries corresponding to the index sets \(F_0 \cup \{m_0\} \cup I\). Since \(|ψ⟩\) is an eigenvalue zero eigenvector of \(A_{G(s)}\) (see Lemma 4.6), it is not supported on the removed entries so \(||ψ|| = ||φ||\) and \(|φ⟩\) is an eigenvalue zero eigenvector of \(A_G\). Thus \(Δ|φ⟩ = |φ⟩\). Since \(Π_s\) is the identity matrix on the support of \(|ψ⟩\), \(Π_s|φ⟩ = |φ⟩\). Together \(U_s|φ⟩ = |φ⟩\).

Now consider the case where \(f(s) = 0\). Let \(|ξ⟩ = \sum_{β:|θ(β)| ≤ Θ}|β⟩⟨β(0)|\): this is the projection of \(|0⟩\) onto low-angle subspaces of \(U_s\). We want to bound \(\sum_{β:|θ(β)| ≤ Θ}|β⟩⟨β(0)|^2 = \sum_{β:|θ(β)| ≤ Θ}⟨0|β⟩⟨β|0⟩ = ⟨0|ξ⟩\). We will find it more convenient to bound \(|⟨0|ξ|^2 = ⟨0|ξ⟩\), where \(|ξ⟩\) is the normalized vector \(|ξ⟩/||ξ||\).

Observe that \(|ξ⟩\) is not supported on any eigenvectors \(|β⟩\) where \(θ(β) = 0\). Without loss of generality, \(θ(β) = 0\) only when \(|β⟩\) is in a one-dimensional subspace \(T_i\) with eigenvalue one. Then \(2πI_i - Δ\) and \((2Δ - Δ)\) either both reflect \(|β⟩\) or they both don’t. In the first case, \(Π_{s,i}|β⟩ = Δ|β⟩ = 0\), so \(⟨0|β⟩ = ⟨0|Π_{s,i}|β⟩ = 0\) because \(Π_s|0⟩ = |0⟩\). In the second case, \(Π_{s,i}|β⟩ = Δ|β⟩ = |β⟩\) and so \(A_{G(s)}|β⟩ = A_{G(s)}Δ|β⟩ = T(I - Π_s)|β⟩ = T(β - β) = 0\), so by the \(f(x) = 0\) case of Lemma 5.1 with \(c = 0\) we have that \(⟨0|β⟩ = 0\).

The observation above implies that if we consider \(Θ < π\) (the Lemma is trivial otherwise), \(e^{iθβ} \neq \pm 1\) for the \(|β⟩\) in the support of \(|ξ⟩\), and so we can restrict our analysis to just the two-dimensional subspaces of \(U_s\). We now split \(|0⟩|ξ⟩\):

\[
⟨0|ξ⟩ = ⟨0|Δ + (I - Δ)|ξ⟩ \\
= ⟨0|Δ|ξ⟩ + ⟨0|Π_s(I - Δ)|ξ⟩ \\
\leq |⟨0|Δ|ξ⟩| + |⟨0|Π_s(I - Δ)|ξ⟩| \quad \text{(by the triangle inequality)} \\
\leq |⟨0|Δ|ξ⟩| + ||Π_s(I - Δ)|ξ⟩||
\]

Now our goal is to bound both of the values in the last expression. First we bound \(||Π_s(I - Δ)|ξ⟩||\).

Given an eigenvector \(|β⟩\) in the support of \(|ξ⟩\), let \(|-β⟩\) be the other eigenvector in the two-dimensional subspace containing \(|β⟩\). Note that \(θ(β) = -θ(-β)\). Let \(|ξ⟩ = \sum_β c_β|β⟩\), where here the sum is over all eigenvectors. Then \(||Π_s(I - Δ)|ξ⟩||^2 = ||\sum_β Π_s(I - Δ)c_β|β⟩||^2\). Thanks to Theorem 5.4, we can break this summation up into pairs.

\[
||Π_s(I - Δ)|ξ⟩||^2 = \sum_{β:θ(β) > 0} ||Π_s(I - Δ)(c_β|β⟩ + c_{-β}| - β⟩)||^2 \\
= \sum_{S:θ_1 θ_2 \neq 0} \left( \frac{i}{\sqrt{2}}(c_{-β} - c_β))Π_s|v_i^⊥\right)^2 \qquad \text{(rewrite }|β⟩, |-β⟩ \text{ in terms of }|v_i⟩, |v_i^⊥\text{)}
\]

\[
= \sum_{S:θ_1 θ_2 \neq 0} \left( \frac{i}{\sqrt{2}}(c_{-β} - c_β) \sin \frac{θ_1}{2}|v_i\right)^2 \qquad \text{(change of basis)}
\]

\[
= \sum_{β:θ(β) > 0} \left( \frac{θ(β)}{2} \right)^2 \left( \frac{i}{\sqrt{2}}(c_{-β} - c_β)|v_i\right)^2 \\
\leq \sum_{β:θ(β) > 0} \left( \frac{θ(β)}{2} \right)^2 \leq \left( \frac{Θ}{2} \right)^2 \quad \text{(sin }θ \leq θ \text{ for the values considered)}
\]

\(^6\)Not just the ones in the support of \(|ξ⟩\)
Next we bound the term $|\langle 0 | \Delta | \hat{\zeta} \rangle|$ which we will write as $|\langle 0 | w \rangle | |\Delta | \hat{\zeta} \rangle|$ where $|w \rangle = \Delta | \hat{\zeta} \rangle / |\Delta | \hat{\zeta} \rangle|$ is the normalized projection of the vector $| \hat{\zeta} \rangle$ onto span of the eigenvalue zero eigenvectors of $A_G$. We will work exclusively with $|w \rangle$. First we bound the magnitude of the vector $|A_G(x) w \rangle$, then decompose $|w \rangle$ into its components in the space of “small” and “large” eigenvalue eigenvectors of $A_G(x)$ for particular choices of “small” and “large”.

$$
|A_G(x) \Delta | \hat{\zeta} \rangle|^2 = |(I - I_x) \Delta | \hat{\zeta} \rangle|^2
= \sum_{\alpha:|\rho(\alpha)| = \beta} \left\| \frac{i}{\sqrt{2}} (c_{\beta} - c_{\beta}) |v_i^\perp \rangle \right\|^2
\quad \text{rewriting $|\beta|, |\beta|$ in terms of $|v_i \rangle, |v_i^\perp \rangle$}
= \sum_{\beta:|\beta| \geq \beta_0} \left( \sin \frac{\theta(\beta)}{2} \right)^2 \left\| \frac{i}{\sqrt{2}} (c_{\beta} - c_{\beta}) |w_i \rangle \right\|^2
\quad \text{(change of basis)}
\leq \left( \frac{\Theta}{2} \right)^2 |\Delta | \hat{\zeta} \rangle|^2.
$$

By the definition of $|w \rangle$, we have

$$
|A_G(x) |w \rangle|^2 = \frac{|A_G(x) \Delta | \hat{\zeta} \rangle|^2}{|\Delta | \hat{\zeta} \rangle|^2} \leq \frac{\Theta}{2}.
$$

For a fixed $d$, to be determined later, let $|w \rangle = |w_{\text{small}} \rangle + |w_{\text{big}} \rangle$ where

$$
|w_{\text{small}} \rangle = \sum_{\alpha:|\rho(\alpha)| \leq d \theta/2} |\alpha \rangle \langle \alpha |w \rangle \quad \text{and} \quad |w_{\text{big}} \rangle = \sum_{\alpha:|\rho(\alpha)| > d \theta/2} |\alpha \rangle \langle \alpha |w \rangle.
$$

Thus we have

$$
|\langle 0 | \Delta | \hat{\zeta} \rangle| = |\langle 0 | w \rangle | |\Delta | \hat{\zeta} \rangle| \leq |\langle 0 | w_{\text{small}} \rangle| + |\langle 0 | w_{\text{big}} \rangle|
$$

where the equality is by definition, the first inequality due to the fact that the projection of the unit vector $| \hat{\zeta} \rangle$, and the second by triangle inequality.

Bound $|\langle 0 | w \rangle|$ as follows:

$$
|\langle 0 | w_{\text{small}} \rangle|^2 = \left( \sum_{\alpha:|\rho(\alpha)| \leq d \theta/2} |\langle 0 | \alpha \rangle|^2 \right)^2
\leq \left( \sum_{\alpha:|\rho(\alpha)| \leq d \theta/2} |\langle 0 | \alpha \rangle|^2 \right) \cdot \left( \sum_{\alpha:|\rho(\alpha)| \leq d \theta/2} |\langle \alpha | w \rangle|^2 \right)
\quad \text{(Cauchy-Schwartz)}
= \left( \sum_{\alpha:|\rho(\alpha)| \leq d \theta/2} |\langle 0 | \alpha \rangle|^2 \right) |w_{\text{small}} \rangle^2
\quad \text{(definition of $|w_{\text{small}} \rangle$)}
\leq 72 c^2 \left( 1 + \frac{1}{W} \right) |w_{\text{small}} \rangle^2
\leq 6 d \Theta W
\quad \text{($W \geq 1$ and $|w \rangle$ is normalized)}
$$

We further have $A_G(x) |w \rangle = \sum_{\alpha} \rho(\alpha) |\alpha \rangle \langle \alpha |w \rangle$ so

$$
\left( \frac{\Theta}{2} \right)^2 \geq |A_G(x) |w \rangle|^2
= |A_G(x) |w_{\text{small}} \rangle|^2 + |A_G(x) |w_{\text{big}} \rangle|^2
\quad \text{(orthogonality of $|\alpha \rangle$)}
\geq d^2 \left( \frac{\Theta}{2} \right)^2 |w_{\text{big}} \rangle^2
$$
Thus $\|w_{\text{big}}\| \leq 1/d$. Since $|0\rangle$ is a column of the identity matrix, $\langle 0 | w_{\text{big}} \rangle \leq \|w_{\text{big}}\|$. Together we have

$$\sqrt{\sum_{\beta:|\theta(\beta)|\leq \Theta} |\langle \beta | 0 \rangle|^2} = \langle 0 | \hat{\xi} \rangle \leq |\langle 0 | \Delta | \hat{\xi} \rangle| + \| \Pi_s(\mathbb{I} - \Delta) | \hat{\xi} \rangle \| \leq |\langle 0 | w_{\text{small}} \rangle| + |\langle 0 | w_{\text{big}} \rangle| + \frac{\Theta}{2} \leq 6d\Theta W + \frac{1}{d} + \frac{\Theta}{2}.$$  

Choosing $d = 1/\sqrt{6\Theta W}$, we find the bound to be $2\sqrt{6\Theta W} + \Theta/2$. □

### 5.2 Analysis of the Algorithms

Given the spectral gap for $U_s$ in Lemma 5.2, we can analyze the algorithms.

Algorithm 1 measures the phase of $U_s$ with input $|0\rangle$, which is in general a superposition of eigenvectors of $U_s$. If $f(s) = 1$ then by Lemma 5.2 most of the amplitude of $|0\rangle$ is in the direction of an eigenvector with phase zero, and so the likelihood of measuring phase zero is at least $9/10$ minus the error $\delta_c$, which gives a probability of at least $4/5$. If $f(s) = 0$, then if we set $\Theta$ to be the precision $\delta_p$ then only a very small amount of the amplitude of $|0\rangle$ is in the direction of eigenvectors with phase zero: by Lemma 5.2, the algorithm will measure a phase of zero with probability at most $\delta_c + (2\sqrt{d\delta_p W + \delta_p/2})^2 < 2/5$.

Algorithm 2 prepares the state $|\varphi\rangle = \frac{1}{\sqrt{2}}(|0\rangle|0\rangle + |1\rangle U_s^T|0\rangle)$ and measures the first qubit in the basis $\{|+\rangle, |-\rangle\}$, which is equivalent to measuring the first qubit of $H|\varphi\rangle = \frac{1}{\sqrt{2}}(|0\rangle|0\rangle + |1\rangle U_s^T|0\rangle - |1\rangle U_s^T|0\rangle)$ in the standard basis. The first qubit of $H|\varphi\rangle$ has amplitude $\frac{1}{2} + \frac{1}{2}(0|U_s^T|0\rangle)$ in the $|0\rangle$ direction, and so we will measure $|0\rangle$ with probability $\frac{1}{4}||I + U_s^T||0\rangle||^2$. When $f(s) = 1$, this probability will be at least $9/10$ regardless of $T$. When $f(s) = 0$,

$$\mathbb{E}_{T \in [\tau]} \left[ \frac{1}{4} ||(I + U_s^T) |0\rangle||^2 \right] = \mathbb{E}_{T \in [\tau]} \left[ \frac{1}{4} \sum_{\beta} |1 + \exp(i\theta(\beta) T)|^2 |0\rangle\langle 0| \right]$$

$$= \frac{1}{4} \sum_{\beta} |0\rangle\langle 0| \frac{1}{\tau} \sum_{T=1}^\tau \left( 2 + 2 \exp(i\theta(\beta) T) \right)$$

$$= \frac{1}{4} \sum_{\beta} |0\rangle\langle 0| \left( 2 + \frac{1}{\tau} \sum_{T=1}^\tau \exp(i\theta(\beta) T) \right)$$

$$= \frac{1}{4} \sum_{\beta} |0\rangle\langle 0| \left( 2 + \frac{1}{\tau} \left( \sum_{T=-\tau}^\tau \exp(i\theta(\beta) T) - \exp(i\theta(\beta) \cdot 0) \right) \right)$$

$$= \frac{1}{4} \sum_{\beta} |0\rangle\langle 0| \left( 2 + \frac{1}{\tau} \left( \exp(i\theta(\beta) (\tau + 1)) - \exp(-i\theta(\beta) \tau) e^{i\theta(\beta)} - 1 \right) \right)$$

We let $\Theta = 1/(50W)$ and define $\nu = (2\sqrt{6\Theta W} + \Theta/2)^2$. Divide the $|\beta\rangle$ by their eigenvalues. For $\theta(\beta) \leq \Theta$,
we use Lemma 5.2 to bound the terms in the sum by \( \nu \). Next consider those \(|\beta\rangle\) such that \( \theta(\beta) > \Theta \).

\[
\sum_{|\beta\rangle: \theta(\beta) > \Theta} |\langle 0 | \beta \rangle|^2 \left( \frac{1}{2} + \frac{1}{4\tau} \left( \frac{\exp(i\theta(\beta)(\tau + 1)) - \exp(-i\theta(\beta)\tau)}{e^{i\theta(\beta)} - 1} - 1 \right) \right)
\]

\[
\leq (1 - \nu) \cdot \left( \frac{1}{2} + \frac{1}{4\tau} \left( \frac{\exp(i\theta(\tau + 1)) - \exp(-i\theta(\tau) - \exp(i\theta) + 1)}{e^{i\theta} - 1} \right) \right)
\]

\[
= (1 - \nu) \cdot \left( \frac{1}{2} + \frac{1}{4\tau} \left( \frac{\sin(\theta(\tau + 1/2)) - \sin(\theta/2)}{\sin(\theta/2)} \right) \right)
\]

\[
= (1 - \nu) \cdot \left( \frac{1}{2} + \frac{1}{4\tau \sin(\theta/2)} \right)
\]

(\( \theta \in (0, \pi] \))

Thus algorithm two outputs 1 with probability at most \( \nu + (1 - \nu) \cdot (1/2 + 1/(4\tau \sin(\theta/2))) \). When \( \tau = \lceil 100W \rceil \) and \( W > 1 \) this probability is at most 88%.

A  Lagrangian Duality

Consider the following objective function:

\[
\begin{align*}
\text{Minimize } & \quad f_0(x) \\
\text{Subject to } & \quad f_i(x) \leq 0 \text{ for } i \in [m] \\
& \quad h_j(x) = 0 \text{ for } j \in [p]
\end{align*}
\]

for \( x \) in some domain \( D \subset \mathbb{R}^n \). Then the associated Lagrangian \( L : \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^j \) is the function

\[
L(|x|, |\lambda|, |\nu|) = f_0(x) + \sum_{i=1}^m \lambda_i f_i(|x|) + \sum_{j=1}^p \nu_j h_j(|x|).
\]

Further, the Lagrangian dual function is

\[
g(|\lambda|, |\nu|) = \inf_{|x| \in D} F(|x|, |\lambda|, |\nu|).
\]

Observe that \( g(|\lambda|, |\nu|) \) is a lower bound for the optimal value \( p^* \) of the objective function above when \( |\lambda| \geq 0 \). Let \( |x| \) be any feasible solution, then \( f_i(|x|) \leq 0 \) and \( h_j(|x|) = 0 \). Thus

\[
p^* \geq f_0(|x|) + \sum_{i=1}^m \lambda_i f_i(|x|) + \sum_{j=1}^p \nu_j h_j(|x|) = L(|x|, |\lambda|, |\nu|) \geq \inf_{|x| \in D} F(|x|, |\lambda|, |\nu|) = g(|\lambda|, |\nu|).
\]

The best lower bound is obtained by maximizing over the dual function. In our case

\[
\begin{align*}
\text{Minimize } & \quad t \\
\text{Subject to } & \quad \sum_{w_j \neq x_j} \langle w, j | X | x, j \rangle = 1 \text{ for all } (x, w) \in \Delta, w_j \neq x_j \\
& \quad \sum_{j \in [n]} \langle s, j | X | s, j \rangle \leq t \text{ for all } s \in \{0, 1\}^n
\end{align*}
\]

where \( X \geq 0 \). The Lagrangian has one variable for every constraint. Let \( Y \geq 0 \) be the variable for the constraint \( X \geq 0 \), \( \alpha_{w,x} \) and \( \beta_s \geq 0 \) be the variables for the equality and inequality constraints respectively. Then

\[
L = L(Y, |\alpha|, |\beta|; X, t) = t - \langle X | Y \rangle + \sum_{(x, w) \in \Delta, w_j \neq x_j} \alpha_{x,w} (1 - \langle w, j | X | x, j \rangle) - \sum_{|s| \in \{0, 1\}^n} \beta_s (t - \langle s, j | X | s, j \rangle)
\]

with dual function

\[
g(Y, |\alpha|, |\beta|) = \inf_{X, t} L(Y, |\alpha|, |\beta|; X, t).
\]

Since the infimum is taken over all \( X \geq 0 \) and values \( t \), there exists choices of \( Y, |\alpha| \) and \( |\beta| \) such that \( \inf_{X \geq 0, t} L(Y, |\alpha|, |\beta|) = -\infty \). To remove these values from consideration, we find the implicit constraints.

Fix \( Y, |\alpha|, |\beta|, X \) and rewrite \( L \) terms of \( t \).

\[
L = t \left( 1 - \sum_{|s| \in \{0,1\}^n} \beta_s \right) - \langle X | Y \rangle + \sum_{(x, w) \in \Delta, w_j \neq x_j} \alpha_{x,w} (1 - \langle w, j | X | x, j \rangle) + \sum_{|s| \in \{0, 1\}^n} \beta_s \langle s, j | X | s, j \rangle.
\]

Since the last three terms are fixed, by taking \( t \to -\infty \), \( L \to -\infty \). Thus we require \( 1 = \sum_{|s| \in \{0,1\}^n} \beta_s \). Similarly, fix \( Y, |\alpha|, |\beta|, t \) and rewrite \( L \) terms of \( X \).

\[
L = \langle X | Z - Y \rangle + t + \sum_{(x, w) \in \Delta} \alpha_{x,w} - t \sum_{|s| \in \{0, 1\}^n} \beta_s
\]

where \( Z = \sum_{|s| \in \{0, 1\}^n} \beta_s |s| - \sum_{(x, w) \in \Delta, w_j \neq x_j} \alpha_{x,w} |w| |x| \). Again, if \( \langle X | Z - Y \rangle \neq 0 \), then \( X \) can be chosen such that \( L \to -\infty \). Thus \( Z = Y \). Since \( Y \geq 0 \), we can simplify this to \( Z \geq 0 \).
B Spectral Analysis of Adjacency and Biadjacency Matrices

Let $G$ be a weighted bipartite graph with biadjacency matrix $B_G \in \mathcal{L}(\mathbb{C}^{U, T})$ and weighted adjacency matrix $A_G \in \mathcal{L}(\mathbb{C}^{T \cup U})$. Further let $|t\rangle \in \mathbb{C}^T$ and $G'$ be the graph with biadjacency matrix

$$B_{G'} = \begin{bmatrix} \mu_0 & U \\ \mu_0^{-1} \bar{B}_G & T \end{bmatrix}$$

and adjacency graph $A_{G'}$. To understand the eigenvectors of the modified adjacency matrix $A_{G'}$, we need the following theorem about eigenvectors of a PSD matrix.

**Theorem B.1.** (Spectral Bounds for PSD Matrices, Theorem 8.9 [RS12].) Let $X \in \mathcal{L}(V)$ with $X \succeq 0$, $|t\rangle \in V$, and $X' = X + |t\rangle\langle t|$. Further, let $\{|\beta\rangle\}$ be the eigenvectors of $X'$ with corresponding eigenvalue $\theta(\beta) \geq 0$. If there exists a vector $|\psi\rangle$ in the null-space of $X$ with $|\langle t|\psi\rangle|^2 \geq \delta ||\psi||^2$, then for any $\gamma \geq 0$

$$\sum_{\beta: \theta(\beta) \leq \gamma, |\langle t|\beta\rangle| \neq 0} \frac{|\langle t|\beta\rangle|^2}{\theta(\beta)} \leq \frac{4\gamma}{\delta}.$$ 

Note that this sum is well defined since $\theta(\beta) \geq 0$ whenever $|\langle t|b\rangle| \neq 0$. One then has $\langle \beta|X'|\beta\rangle = \langle \beta|X|\beta\rangle + ||\langle t|\beta\rangle||^2 > 0$.

**Theorem B.2.** (Spectral Properties of Small Eigenvalue Eigenvectors.) Let $G$, $B_G$, $A_G$, $G'$, $B_{G'}$, and $A_{G'}$ be as before. Suppose for some $\delta > 0$, $A_G$ has an eigenvalue zero eigenvector such that

$$|\langle t|\psi\rangle|^2 \geq \delta ||\psi||^2.$$ 

Let $\{|\alpha\rangle\}$ be the complete set of orthonormal eigenvectors of $A_{G'}$ with corresponding eigenvalues $\rho(\alpha)$. Further, let $|0\rangle$ be the vector $[0, 1, 0]^T \in \mathbb{C}^{T \cup U \cup U}$. Then for all $\gamma > 0$, we have

$$\sum_{\alpha: \rho(\alpha) \leq \gamma} |\langle 0|\alpha\rangle|^2 \leq \frac{8\gamma^2}{\delta}.$$ 

**Proof.** The structure of the proof is as follows. We begin by reviewing relationships between the eigenvectors and eigenvalues of the adjacency graph $A_G$ and the biadjacency graph $B_G$. Given an eigenvector of $A_G$, we will relate this to the eigenvectors of the modified adjacency matrix $A_{G'}$ and modified biadjacency graph $B_{G'}$. Central to this analysis will be the study of PSD matrix $B_{G'}B_{G'}^*$. Let $G$ be a graph and $A_G$ and $B_G$ be its adjacency and biadjacency matrices as described in the theorem statement. Let $|\psi\rangle = (|\psi_T\rangle, |\psi_U\rangle) \in \mathbb{C}^{T \cup U}$ be an eigenvector of $A_G$ with associated eigenvalue $\rho > 0$ i.e.

$$\begin{bmatrix} 0 & B_G \\ B_G^* & 0 \end{bmatrix} \begin{bmatrix} |\psi_T\rangle \\ |\psi_U\rangle \end{bmatrix} = \rho \begin{bmatrix} |\psi_T\rangle \\ |\psi_U\rangle \end{bmatrix}.$$

Then we obtain the identities $B_G|\psi_U\rangle = \rho|\psi_T\rangle$ and $B_G^*|\psi_T\rangle = \rho|\psi_U\rangle$. By negating these identities, we observe that $(|\psi_T\rangle, -|\psi_U\rangle)$ is also an eigenvector of $A_G$ with associated eigenvalue $-\rho$. Observe further that $|\psi_T\rangle$, defined to be $\frac{1}{\rho} B_G|\psi_U\rangle$, is an eigenvector of $B_G^*B_G$ with eigenvalue $\rho^2$. Similarly, $|\psi_U\rangle$, defined to be $\frac{1}{\rho} B_G^*|\psi_T\rangle$, is an eigenvector of $B_G^*B_G$ with eigenvalue $\rho^2$. If, instead, we begin with an eigenvector $|\phi\rangle \in \mathbb{C}^T$ of $B_G^*B_G$ with eigenvalue $\lambda$, then $B_G^*|\phi\rangle \in \mathbb{C}^U$ is an eigenvalue of $B_G^*B_G$ with eigenvalue $\lambda$ then

$$B_G^*B_G (B_G^*|\phi\rangle) = \lambda B_G^*|\phi\rangle.$$ 

The pair $(|\phi\rangle, \pm \frac{1}{\sqrt{\lambda}} B_G^*|\phi\rangle)$ are eigenvectors of $A_G$ with eigenvalues $\pm \sqrt{\lambda}$ since, in the positive case for example,

$$B_G \left( \frac{1}{\sqrt{\lambda}} B_G^*|\phi\rangle \right) = \sqrt{\lambda}|\phi\rangle$$ and $B_G^*|\phi\rangle = \sqrt{\lambda} \left( \frac{1}{\sqrt{\lambda}} B_G^*|\phi\rangle \right)$.
Let \(|\psi_T\rangle, 0\rangle\), an eigenvector of \(A_G\), be the input to our theorem. Note that \(|\langle t|\psi_T\rangle|^2 \geq \delta \|\psi\|^2\) and \(B_G^*|\psi_T\rangle = 0\). We would like to bound the magnitude of
\[
\sum_{\alpha: |\rho(\alpha)| \leq \gamma} |\langle \alpha|0\rangle|^2
\]
where \(|\{\alpha\}\rangle\) is a complete set of orthonormal eigenvectors of \(A_G\) with associated eigenvalue \(\rho(\alpha)\) and \(|0\rangle\) is the indicator vector for entry corresponding to \(\mu_0\). First we show that the eigenvalue zero eigenvectors of \(A_G\) are unsupported on \(\mu_0\) so will not contribute to this sum. We bound \(|\langle \alpha|0\rangle|^2\) for eigenvectors \(|\alpha\rangle\) with \(0 < \rho(\alpha) \leq \gamma\) using Theorem B.1 by considering the eigenvectors of \(B_GB_G^*\).

Let \(|\zeta\rangle = (|\zeta_T\rangle, \zeta_{\mu_0}, |\zeta_U\rangle)\) be an eigenvalue zero eigenvector of \(A_G\). Then modified biadjacency matrix \(B_G\) must satisfy
\[
B_G'(|\zeta_{\mu_0}\rangle, |\zeta_U\rangle) = [t] B_G \cdot \left[ \begin{array}{c} \zeta_{\mu_0} \\ |\zeta_U\rangle \end{array} \right] = B_G |\zeta_U\rangle = 0.
\]
By multiplying both sides by \(\langle \psi_T|\), we have
\[
\zeta_{\mu_0}\langle \psi_T|t\rangle + \langle \psi_T|B_G|\zeta_T\rangle = 0,
\]
since \(B_G|\psi_T\rangle = 0\) and \(|\langle t|\psi_T\rangle| > 0\), \(\zeta_{\mu_0} = 0\). Thus eigenvalue zero eigenvectors of \(A_G\) are orthogonal to \(|0\rangle\).

It remains to consider those eigenvectors \(|\alpha\rangle = (|\alpha_T\rangle, \alpha_{\mu_0}, |\alpha_U\rangle)\) of \(A_G\) with \(\rho(\alpha) > 0\). First, using the definition of eigenvectors and the property that \(A_G|0\rangle = |t\rangle\), we have
\[
\rho(\alpha)|\alpha\rangle = (\alpha|A_G|0\rangle = |\alpha_T\rangle).
\]
Substituting this into our desired sum, we obtain
\[
\sum_{\alpha:0 < |\rho(\alpha)| \leq \gamma} |\langle \alpha|0\rangle|^2 = \sum_{\alpha:0 < |\rho(\alpha)| \leq \gamma} \frac{|\langle \alpha_T|t\rangle|^2}{\rho(\alpha)^2}.
\]
Let \(B_G, B_G^*\) be a matrix with eigenvectors \(|\beta\rangle\) and corresponding eigenvalues \(\theta(\beta)\). By the relationship between the eigenvalues and eigenvectors of \(A_G\) and \(B_G^*\) considered above, each \(|\beta\rangle\) with \(\theta(\beta)\) corresponds to two eigenvectors of \(A_G\) with eigenvalue \(\left(|\beta\rangle, \frac{1}{\sqrt{\theta(\beta)}} B_G^*|\beta\rangle\right)\) with \(\pm \sqrt{\theta(\beta)}\). Thus
\[
\sum_{\alpha:0 < |\rho(\alpha)| \leq \gamma} \frac{|\langle \alpha_T|t\rangle|^2}{\rho(\alpha)^2} = \sum_{\beta: \theta(\beta) \leq \gamma^2, \theta(\beta) \neq 0} \frac{|\langle \beta|t\rangle|^2}{\theta(\beta)}.
\]
Using Theorem B.1 with \(X = B_G^*B_G - |t\rangle\langle t|\) and \(|\psi_T\rangle\) gives us the bound
\[
\sum_{\alpha:|\rho(\alpha)| \leq \gamma} |\langle \alpha|0\rangle|^2 = 2 \sum_{\beta: \theta(\beta) \leq \gamma^2, \theta(\beta) \neq 0} \frac{|\langle \beta|t\rangle|^2}{\theta(\beta)} \leq \frac{8\gamma^2}{\delta}
\]
as required. \(\square\)

Applying Theorem B.2 with \(\delta = 1/(9W(W + 1))\) and \(\gamma = c/W\) to Lemma 4.6 in the case where \(f(s) = 0\), we obtain the following Lemma 5.1.
