Abstract

In recent centralized nonconvex distributed learning and federated learning, local methods are one of the promising approaches to reduce communication time. However, existing work has mainly focused on studying first-order optimality guarantees. On the other side, second-order optimality guaranteed algorithms, i.e., algorithms escaping saddle points, have been extensively studied in the non-distributed optimization literature. In this paper, we study a new local algorithm called Bias-Variance Reduced Local Perturbed SGD (BVR-L-PSGD), that combines the existing bias-variance reduced gradient estimator with parameter perturbation to find second-order optimal points in centralized nonconvex distributed optimization. BVR-L-PSGD enjoys second-order optimality with nearly the same communication complexity as the best known one of BVR-L-SGD to find first-order optimality. Particularly, the communication complexity is better than non-local methods when the local datasets heterogeneity is smaller than the smoothness of the local loss. In an extreme case, the communication complexity approaches to $\Theta(1)$ when the local datasets heterogeneity goes to zero. Numerical results validate our theoretical findings.

1 Introduction

Distributed learning is an attractive approach to reduce the total execution time by utilizing the parallel computations. However, the communication time in distributed learning can be a main bottleneck in the entire process due to huge parameter size typical in deep learning or low bandwidth communication environments.

To reduce communication time, one of the promising approaches is the usage of local methods such as local SGD (also called as Parallel Restart SGD or FedAvg). In local SGD, each worker independently executes multiple updates of the local model based on his own local dataset, and the server periodically communicates and aggregates the local models. Many paper have studied local SGD [26, 31, 7, 6, 16, 14, 29, 28]. Particularly, for convex objectives, it has been shown in [28], for
the first time, the communication complexity (that is the necessary number of communication rounds to achieve given desired optimization error) of local SGD can be smaller than the one of minibatch SGD when the heterogeneity of the local datasets is extremely small. In traditional distributed learning, the local datasets are typically random subsets of the global dataset and in this case the heterogeneity of the local datasets may become quite small. However, in the recent federated learning regimes \cite{FedAvg, FL, MDA}, it is often the case that the heterogeneity of the local datasets is not too small. Also, the analysis in \cite{FedAvg2} has only focused on convex cases. Hence, the superiority of local SGD to minibatch SGD is still quite limited.

Recently, more communication efficient local methods than local SGD have been proposed for possibly nonconvex objectives to guarantee first-order optimality \cite{SCAFFOLD, BVR-L-SGD, BVR-L-PSGD}. SCAFFOLD \cite{SCAFFOLD} is a new local algorithm based on the idea of reducing their called client-drift by using a similar formulation to the variance reduction technique \cite{VR}. They have shown that the communication complexity of SCAFFOLD can be smaller than the one of minibatch SGD for not too heterogeneous local datasets under the \textit{quadraticity} of the (possibly nonconvex) local objectives, which is quite limited. For general nonconvex objectives, the communication complexity of SCAFFOLD is same as minibatch SGD. More recently, Murata and Suzuki \cite{BVR-L-SGD} have proposed Bias-Variance Reduced Local SGD (BVR-L-SGD). BVR-L-SGD utilizes their proposed \textit{bias-variance reduced estimator} that simultaneously reduces the bias caused by local gradient steps and the variance caused by stochasticization of the gradients in local optimization based on the formulation of SARAH like variance reduction \cite{BVR-L-PSGD}. They have shown that the communication complexity of BVR-L-SGD is smaller than minibatch SGD for not too heterogeneous local datasets \textit{for general nonconvex objectives}. Specifically, BVR-L-SGD is superior to minibatch SGD when the Hessian heterogeneity of the local datasets is small relative to the smoothness of the local loss in order sense.

On the other side, there are vast work that has studied second-order optimality guarantees, which is much more challenging to ensure but desirable than first-order one, in non-distributed nonconvex optimization. Several approaches are known and one of the simplest approaches is parameter perturbation \cite{4, 8, 10}. However, almost all existing analysis of local methods have only focused on achieving first-order optimality. As an exception, Vlaski et al. \cite{Vlaski} have analysed second-order guarantees of local SGD with parameter perturbation, but the obtained communication complexity is much worse than the one of minibatch SGD and no benefit of localization has been shown.

\textbf{Open question.} For local methods, it is not well-studied how to find second-order optimal points with low communication cost and thus we have the following research questions: \textit{Is there a first-order distributed optimization algorithm with second-order optimality guarantees which satisfies that (i) the communication complexity is smaller than non-local methods for not too heterogeneous local datasets; and (ii) the communication complexity approaches to $\Theta(1)$ when the heterogeneity of local datasets goes to zero?}

Note that the both properties are desirable in distributed optimization. We expect that local methods are superior to non-local methods for not highly heterogeneous local datasets. Furthermore, when the local datasets are nearly identical, it is expected that a few communications are sufficient to optimize the global objective. \textit{Only in the case of first-order optimality}, Murata and Suzuki \cite{BVR-L-PSGD} have shown that their proposed BVR-L-SGD satisfies (i) and (ii), and the question has been positively answered. However, the question is still open in the case of second-order optimality.

\textbf{Main Contributions}

We propose a new local algorithm called Bias-Variance Reduced Local \textit{Perturbed} SGD (BVR-L-PSGD) for nonconvex distributed learning to efficiently find second-order optimal points, which positively answered the above research questions.

\footnote{Since there are communication efficient distributed optimization algorithms that find first-order stationary points like BVR-L-SGD, we can apply generic algorithms which guarantee second-order optimality to them \cite{30, 1}. However, this naive approach does not possess the aforementioned property (ii) because the generic framework requires at least $\Omega(1/\epsilon^{3/2})$ communication rounds to guarantee second-order optimality due to the multiple negative curvature exploitation steps in their framework for any communication efficient algorithms with first-order optimality guarantees. Also, this approach requires explicit negative curvature exploitation, that is complicated and makes the whole algorithm less practical.}
We analyse BVR-L-PSGD for general nonconvex smooth objectives. The most challenging part of work and has a unique difficulty of our analysis.

Table 1: Comparison of the order of the necessary number of communication rounds to achieve desired optimization error \( \varepsilon \) in terms of given optimization criteria (described in the column of "Guarantee") in nonconvex optimization. "Assumptions" indicates the necessary assumptions to derive the results (the numbers correspond to Assumptions 2, 3, 4, 5 in Section 2 respectively). BSGV means the bounded stochastic gradient variance assumption, that is \( \mathbb{E}_{z \sim D_p} \| \nabla f_p(x) - \nabla f(x) \|^2 \leq \sigma^2 \). B is the local computation budget, which is defined in Section 2. \( P \) is the number of workers. \( n \) is the total number of samples. The gradient Lipschitzness \( L \), Hessian Lipschitzness \( \rho \), the gradient boundedness \( G \) are regarded as \( \Theta(1) \) for ease of presentation. In this notation, Hessian heterogeneity \( \zeta \) always satisfies \( \zeta \leq \Theta(L) = \Theta(1) \).

The algorithm is based on a simple combination of the existing bias and variance reduced gradient estimator and parameter perturbation. In our algorithm, parameter perturbation is carried out at every local update and it is not necessary to determine whether or not to add noise by checking the norm of the global gradients, which is often required in several previous non-distributed algorithms [5, 18].

We analyse BVR-L-PSGD for general nonconvex smooth objectives. The most challenging part of our analysis is to ensure that our algorithm efficiently escapes global saddle points even in local optimization. To realize this, it is necessary to analyse the behavior of the bias-variance reduced estimator around the saddle points by carefully evaluating the degree of some kind of asymptotic consistency of the estimator around the saddle points. This point has never been pursued in previous work and has a unique difficulty of our analysis.

The comparison of the communication complexities of our method with the most relevant existing results is given in Table 1. Our proposed method enjoys second-order optimality with nearly the same communication complexity as the one of BVR-L-SGD, which achieves the best known communication complexity to achieve first-order optimality. This means that our method finds second-order optimal points without hurting the communication efficiency of the state-of-the-art first-order optimality guaranteed method. Particularly, the communication complexity is better than minibatch SGD when Hessian heterogeneity \( \zeta \) is small relative to smoothness \( L \). Also, the communication complexity approaches to \( \tilde{O}(1) \) when heterogeneity \( \zeta \) goes to zero and the local computation budget \( B \) (see Section 2) goes to infinity. Hence, our method enjoys the aforementioned two desired properties.

### Related Work

Here, we briefly review the related studies to our paper.

#### Local methods.
Several recent papers have studied local algorithms combined with variance reduction technique [24, 2, 15, 12]. Sharma et al. [24] have proposed a local variant of SPIDER [3] and shown that the proposed algorithm achieves the optimal total computational complexity. However, the communication complexity essentially matches the ones of non-local SARAH and no advantage of localization has been shown. Khanduri et al. [15] have proposed STEM and its variants based on their called two-sided momentum, but again the communication complexity does not improve non-local methods. Also, Das et al. [2] have considered a SPIDER like local algorithm called FedGLOMO but the derived communication complexity is even worse than minibatch SARAH. Karimireddy et al. [12] have proposed Mime, which is a general framework to mitigate client-drift. Particularly, under \( \delta \)-Bounded Hessian Dissimilarity (BHD) [1], their MimeMVR achieves communication complexity of
1/(P\varepsilon^2) + \delta/(\sqrt{P}\varepsilon^3) + \delta/\varepsilon^2 \text{ when } B \to \infty, \text{ that is better than the one of minibatch SGD } 1/\varepsilon^2 \text{ when } \delta \leq \sqrt{P}\varepsilon. \text{ However, the asymptotic rate is still worse than the one of BVR-L-SGD } \zeta/\varepsilon^2 \text{ because } \zeta \leq \delta \text{ always holds.}

**Second-order guarantee.** Neon \([30]\) and Neon2 \([11]\) are generic first-order methods with second-order guarantees, that repeatedly run a first-order guaranteed algorithm and negative curvature descent. Another approach is a parameter perturbation for SGD. For the first time, Ge et al. \([4]\) have shown that SGD with a simple parameter perturbation escapes saddle points efficiently. Later, the analysis has been refined by \([8, 10]\). Recently, applying variance reduction technique to second-order guaranteed methods has been also studied \([5, 18]\) and particularly Li et al. \([18]\) have proposed SSRGD that combines SARAH \([21]\) with parameter perturbation and shown that SSRGD nearly achieves the optimal computational complexity with second-order optimality guarantees.

## 2 Problem Definition and Assumptions

In this section, we first introduce several notations and definitions used in this paper. Then, the problem settings are described and theoretical assumptions used in our analysis are given.

**Notation.** \(\| \cdot \|\) denotes the Euclidean \(L_2\) norm \(\| x \|_2 = \sqrt{\sum x_i^2}\) for vector \(x\). For a matrix \(X\), \(\| X \|\) denotes the induced norm by the Euclidean \(L_2\) norm. For a natural number \(m, [m]\) means the set \([1, 2, \ldots, m]\). For a set \(A\), \#\(A\) means the number of elements, which is possibly \(\infty\). For any number \(a, b, a \lor b\) and \(a \land b\) denote \(\max\{a, b\}\) and \(\min\{a, b\}\) respectively. We denote the uniform distribution over \(A\) by \(\text{Unif}(A)\). Given \(K, T, S \in \mathbb{N}\), let \(I(k, t, s)\) be integer \(k + Kt + KTs\) for \(k \in [K] \cup \{0\}\), \(t \in [T - 1] \cup \{0\}\) and \(s \in [S - 1] \cup \{0\}\). Note that \(I(k, t, s) = I(0, t + 1, s)\) and \(I(k, t, s) = I(k, 0, s + 1)\) for \(k \in [K] \cup \{0\}\), \(t \in [T - 1] \cup \{0\}\) and \(s \in [S - 1] \cup \{0\}\). \(B_r^d\) denotes the set \(\{x \in \mathbb{R}^d \mid \| x \| \leq r\}\), which is the Euclidean ball in \(\mathbb{R}^d\) with radius \(r\).

**Definition 2.1** (Gradient Lipschitzness). A differentiable function \(f : \mathbb{R}^d \to \mathbb{R}\) is \(L\)-gradient Lipschitz if \(\| \nabla f(x) - \nabla f(y) \| \leq L\| x - y\|\), \(\forall x, y \in \mathbb{R}^d\).

**Definition 2.2** (Hessian Lipschitzness). A twice differentiable function \(f : \mathbb{R}^d \to \mathbb{R}\) is \(\rho\)-Hessian Lipschitz if \(\| \nabla^2 f(x) - \nabla^2 f(y) \| \leq \rho\| x - y\|\), \(\forall x, y \in \mathbb{R}^d\).

**Definition 2.3** (Second-order optimality). For a \(\rho\)-Hessian Lipschitz function \(f, x \in \mathbb{R}^d\) is an \(\varepsilon\)-second-order optimal point of \(f\) if \(\| \nabla f(x) \| \leq \varepsilon\) and \(\nabla^2 f(x) \succeq -\sqrt{\rho}\varepsilon I\).

### 2.1 Problem Settings

**Objective function.** We want to minimize nonconvex smooth objective \(f(x) := \frac{1}{P} \sum_{p=1}^{P} f_p(x)\), where \(f_p(x) := \mathbb{E}_{z \sim D_p}[\ell(x, z)]\) for \(x \in \mathbb{R}^d\), where \(D_p\) is the data distribution associated with worker \(p\). In this paper, we focus on offline settings (i.e., \(#\text{supp}(D_p) < \infty\) for every \(p \in [P]\)) for simple presentation. It is easy to extend our results to online settings. Also, just for simplicity, it is assumed that each local dataset has an equal number of samples, i.e., \(#\text{supp}(D_p) = n/P\) for every \(p, p' \in [P]\), where \(n\) is the total number of samples.

**Optimization criteria.** Since objective function \(f\) is nonconvex, it is generally difficult to find a global minima of \(f\). Previous work in distributed learning has mainly focused on finding first-order stationary points of \(f\). In this study, we aim to find \(\varepsilon\)-second-order stationary points of \(f\) in distributed learning settings.

**Data access constraints and communication settings.** It is assumed that each worker \(p\) can only access the own data distribution \(D_p\) without communication. Aggregation (e.g., summation) of all the worker’s \(d\)-dimensional parameters or broadcast of a \(d\)-dimensional parameter from one worker to the other workers can be realized by single communication.\(^4\)

**Evaluation criteria: communication complexity.** In this paper, we compare communication complexities of optimization algorithms to satisfy the aforementioned optimization criteria. In typical situations, single communication is more time-consuming than single stochastic gradient computation. Let \(C\) be the single communication cost and \(G\) be the single stochastic gradient computation cost.\(^4\)

\(^4\)\(\delta\)-BHD condition in \([12]\) requires \(\| \nabla^2 \ell(x, z) - \nabla^2 f(x) \| \leq \delta\) for every \(x \in \mathbb{R}^d, z \sim D_p\) and \(p \in [P]\). Note that \(\delta\)-BHD condition requires both intra Hessian dissimilarity boundedness \(\| \nabla^2 f_1(x) - \nabla^2 f_2(x) \|\), which is bounded by \(\zeta\) under Assumption \([1]\) and additionally inner Hessian dissimilarity \(\| \nabla^2 \ell(x, z) - \nabla^2 f(x) \|\). Hence, \(\delta\)-BHD is much stronger than Assumption \([1]\) and it is possible that \(\delta \gg \zeta\).
Using these notations, \( C \geq G \) is assumed. We expect that increasing the number of available stochastic gradients in a single communication round leads to faster convergence. Hence, it is natural to increase the number of stochastic gradient computations in a single communication round unless the total stochastic gradient computation time exceeds \( C \) to reduce the total running time. This motivates the concept of local computation budget \( B (\leq C/G) \): given a communication and computational environment, it is assumed that each worker can only computes at most \( B \) single stochastic gradients per communication round on average. Then, we compare the communication complexity, that is the total number of communication rounds of a distributed optimization algorithm to achieve the desired optimization accuracy. From the definition, we can see that the communication complexity on a fixed local computation budget \( B := C/G \) captures the best achievable total running time of an algorithm.

### 2.2 Theoretical Assumptions

In this paper, we assume the following five assumptions. The first one has already been adopted in several previous work \([13, 20]\). The other ones are standard in the nonconvex optimization literature to guarantee second-order optimality.

**Assumption 1** (Hessian heterogeneity \([13, 20]\)). \( \{f_p\}_{p=1}^P \) is second-order \( \zeta \)-heterogeneous, i.e., for any \( p, p' \in [P] \), \( \| \nabla^2 f_p(x) - \nabla^2 f_{p'}(x) \| \leq \zeta, \forall x \in \mathbb{R}^d \).

**Assumption 2** characterizes the heterogeneity of local objectives \( \{f_p\}_{p=1}^P \) in terms of Hessians and has an important role in our analysis. Intuitively, we expect that relatively small heterogeneity parameter \( \zeta \) to the smoothness parameter \( L \) (defined in Assumption 2) reduces the necessary number of communication rounds to optimize the global objective. Especially when the local objectives are identical, i.e., \( D_p = D_{p'} \) for every \( p, p' \in [P] \), \( \zeta \) becomes zero. When each \( D_p \) is the empirical distribution of \( n/P \) IID samples from common data distribution \( D \), we have \( \| \nabla^2 f_p(x) - \nabla^2 f_{p'}(x) \| \leq \Theta(\sqrt{P/nL}) \) with high probability by matrix Hoeffding’s inequality under Assumption 2 for fixed \( x \). Hence, in traditional distributed learning regimes, Assumption 1 naturally holds. An important remark is that Assumption 2 implies \( \zeta \leq 2L \), i.e., the heterogeneity is bounded by the smoothness. Even in federated learning regimes, we expect \( \zeta \ll 2L \) for some problems practically.

**Assumption 2** (Gradient Lipschitzness). \( \forall p \in [P], z \in \text{supp}(D_p), \ell(\cdot, z) \) is \( L \)-gradient Lipschitz.

**Assumption 3** (Existence of global optimum). \( f \) has a global minimizer \( x* \in \mathbb{R}^d \).

**Assumption 4** (Hessian Lipschitzness). \( \forall p \in [P], z \in \text{supp}(D_p), \ell(\cdot, z) \) is \( \rho \)-Hessian Lipschitz.

**Assumption 5** (Bounded stochastic gradient). \( \forall p \in [P], z \in \text{supp}(D_p), \nabla \ell(\cdot, z) \) is \( G \)-bounded, i.e., \( \| \nabla \ell(x, z) \| \leq G, \forall x \in \mathbb{R}^d \).

In our analysis, \( G \) has no significant impact because \( G \) only depends on our theoretical communication complexity in logarithmic order.

### 3 Main Ideas and Proposed Algorithm

Our proposed algorithm is based on a natural combination of (i) Bias-Variance Reduced (BVR) estimator; and (ii) parameter perturbation at each local update. The first idea has been proposed by \([20]\) to find first-order stationary points with small communication complexity. The second one is a well-known approach to find second-order stationary points in non-distributed nonconvex optimization \([4, 8, 10]\). In this section, we illustrate these two ideas and provide its concrete procedures.

#### 3.1 Review of BVR Estimator \([20]\)

The bias-variance reduced estimator aims to efficiently find first-order stationary points by simultaneously reducing the bias caused by local gradient descent steps and the variance caused by stochastization of the used gradients.

First we consider why the standard local SGD is not sufficient to achieve fast convergence and sometimes slower than minibatch SGD. Recall that in local SGD each worker takes the update rules

---

\(^5\)In this work, it is assumed that all the workers can participate in a single communication. It is not so hard to extend our algorithm and analysis to worker sampling settings, which is more realistic in cross-device federated learning.
Algorithm 1 BVR-L-PSGD($\bar{x}_0$, $\eta$, $b$, $K$, $T$, $S$, $r$)

1: Add noise $x_0 = \bar{x}_0 + \eta \xi_0$, where $\xi_0 \sim \text{Unif}(B^d_r)$.
2: for $s = 0$ to $S - 1$ do
3:  for $p = 1$ to $P$ in parallel do
4:  $v^{(p)}_{I(0,0,s)} = \nabla f_p(x_{I(0,0,s)})$.
5:  end for
6:  Communicate $\{v^{(p)}_{I(0,0,s)}\}_{p=1}^P$. Set $v_{I(0,0,s)} = \frac{1}{P} \sum_{p=1}^P v^{(p)}_{I(0,0,s)}$.
7: for $t = 0$ to $T - 1$ do
8:  for $p = 1$ to $P$ in parallel do
9:  $g_{I(0,t,s)}^{(p)} = \frac{1}{Kb} \sum_{k=1}^{Kb} \nabla \ell(x_{I(0,t,s)}, z_{I(0,t,s)})$, 
10: $g_{I(t,k,t,s)}^{(p),\text{ref}} = \frac{1}{Kb} \sum_{k=1}^{Kb} \nabla \ell(x_{I(0,t-1,s)}, z_{I(t-1,s)}) (z_{I(t-1,s)} \sim \text{i.i.d.} D_p)$.
11: $v_{I(t,k,t,s)} = 1_{t \geq 1} (g_{I(t,k,t,s)}^{(p)} - g_{I(t,k,t,s)}^{(p),\text{ref}} + v_{I(k-1,t,s)}) + 1_{t=0} v_{I(0,t,s)}^{(p)}$.
12: end for
13: Communicate $\{v_{I(0,t,s)}\}_{p=1}^P$. Set $v_{I(0,t,s)} = \frac{1}{P} \sum_{p=1}^P v_{I(0,t,s)}^{(p)}$.
14: Randomly select $p_{t,s} \sim \text{Unif}[P]$. # Only worker $p_{t,s}$ runs local optimization.
15: for $k = 0$ to $K - 1$ do
16:  $b_k = 1_{k=0 \text{ (mod } [\sqrt{K}])} [\sqrt{K}] b + 1_{k=0 \text{ (mod } [\sqrt{K}])} b$.
17:  $g_{I(k+1,t,s)} = \frac{1}{b_k} \sum_{k=1}^{b_k} \nabla \ell(x_{I(k,0,s)}, z_{I(k,0,s)})$.
18:  $g_{I(0,k,s)}^{(p),\text{ref}} = \frac{1}{b_k} \sum_{k=1}^{b_k} \nabla \ell(x_{I(k-1,0,s)}, z_{I(k-1,0,s)}) (z_{I(k-1,0,s)} \sim \text{i.i.d.} D_{p_{t,s}})$.
19:  $v_{I(k+1,t,s)} = 1_{k \geq 1} (g_{I(k+1,t,s)} - g_{I(0,k,s)}^{(p),\text{ref}} + v_{I(k-1,t,s)}) + 1_{k=0} v_{I(0,t,s)}^{(p)}$.
20: Update $x_{I(k+1,t,s)} = x_{I(k+1,t,s)} - \eta v_{I(k+1,t,s)}$.
21: Add noise $x_{I(k+1,t,s)} = \bar{x}_{I(k+1,t,s)} + \eta \xi_{I(k+1,t,s)}$, where $\xi_{I(k+1,t,s)} \sim \text{Unif}(B^d_r)$.
22: end for
23: Communicate $x_{I(0,t+1,s)}$.
24: end for
25: end for

of $x_{k+1}^{(p)} = x_{k}^{(p)} - \eta g_{k}^{(p)}$ for $k \in [B/b]$ in each communication round, where $g_{k}^{(p)}$ is a stochastic gradient with minibatch size $b$ at $x_{k}^{(p)}$ on local dataset $D_p$ and $B$ is given local computation budget. In typical convergence analysis, we need to bound the expected deviation of $g_{k}^{(p)}$ from ideal global gradient $\nabla f(x_k)$, that is $\mathbb{E}||g_{k}^{(p)} - \nabla f(x_k^{(p)})||^2 = ||\nabla f_p(x_k^{(p)}) - \nabla f(x_k^{(p)})||^2 + \mathbb{E}||g_{k}^{(p)} - \nabla f_p(x_k^{(p)})||^2$. The former term is called bias and the latter one is called variance. A typical assumption to bound the first term is bounded gradient heterogeneity assumption, that requires $||\nabla f_p(x) - \nabla f(x)|| \leq \zeta_1$ for every $x \in \mathbb{R}^d$ and $p \in [P]$. Under this assumption, the first term is only bounded by $\zeta_1$, that is a constant. The second term is typically bounded by $\sigma^2/b$ for $g_{k}^{(p)}$ with minibatch size $b$, when the variance of a single stochastic gradient is bounded by $\sigma^2$. These facts show that the bias is still a constant and does not vanish even if minibatch size $b$ is enhanced and the variance vanishes. This is why local SGD can be worse than minibatch SGD when $\zeta_1$ is not too small. Also, we can see that the variance is still a constant for fixed minibatch size $b$ and this is a common reason why minibatch SGD and local SGD only show slow convergences. These observations give critical motivations of the simultaneous reduction of the bias and variance.

The bias-variance reduced estimator $v_{k}^{(p)}$ is defined as $v_{k}^{(p)} := (1/b) \sum_{l=1}^{b} (\nabla \ell(x_{k}^{(p)}, z_l) - \nabla \ell(x_0, z_l)) + \nabla f(x_0)$ (SVRG version). It is known that the bias caused by localization can be bounded by $\zeta ||x_{k}^{(p)} - x_0||$ and the variance caused by stochastization can be bounded by $(L^2/b) ||x_{k}^{(p)} - x_0||^2$, where $\zeta$ is the Hessian heterogeneity of $\{f_p\}$ and $L$ is the smoothness of $\ell$. This implies that both the bias and variance of $v_{k}^{(p)}$ converges to zero as $x_{k}^{(p)}$ and $x_0$ go to $x_*$.

In other words, bias-variance reduced estimator $v_{k}^{(p)}$ is asymptotically consistent to the global gradient $\nabla f(x_{k}^{(p)})$ by using periodically computed global full gradients $\nabla f(x_0)$. We actually adopt SARAH version of BVR estimator as in [20] rather than SVRG one due to its theoretical advantages.
3.2 Parameter Perturbation at Local Updates

Although the bias-variance reduced estimator is useful to guarantee first-order optimality with small communication complexity in nonconvex optimization, the algorithm often gets stuck at saddle points. To tackle this problem, we borrow the ideas of escaping saddle points in non-distributed nonconvex optimization. Parameter perturbation is a familiar approach in non-distributed nonconvex optimization. Specifically, Jin et al. [8, 10] have considered the update rule of \( x_{k+1} = x_k - \eta \nabla f(x_k) + \eta \xi_k \), where \( \xi_k \sim \text{Unif}(B^d_r) \) for some small radius \( r \). This algorithm is called Perturbed GD (PGD) or Noisy GD. Similar to this formulation, we add noise at each local update, i.e., \( x_{k+1}^{(p)} = x_k^{(p)} - \eta v_k^{(p)} \). The intuition behind the noise addition is that random noise has some components along the negative curvature directions of the global objective around the saddle point, and we expect that noise addition helps the parameter proceed to the decreasing directions of \( f \) and escape the saddle points.

Necessity of local perturbation. Perturbing the global model at the server side is an intuitive way, but not sufficient for communication efficiency when we want to utilize small heterogeneity of the local datasets (i.e., \( \zeta \ll L \)). The bias-variance reduced estimator with local perturbation enables to escape multiple global saddle points in local optimization and achieves second-order optimality with communication complexity \( \tilde{\Theta}(\zeta/e^2) \) for sufficiently large \( B \). In contrast, perturbing the global parameter at the server side only ensures to escape single global saddle point at each round and only achieves communication complexity of \( \tilde{\Theta}(L/e^2) \). This is the reason why local perturbation rather than global one is adopted.

3.3 Concrete Procedures

The full description of our proposed Bias-Variance Reduced Local Perturbed SGD (BVR-L-PSGD) is given in Algorithm 1. When we set the noise size \( r = 0 \), Algorithm 1 essentially matches BVR-L-SGD. Additionally setting \( K = 1 \), Algorithm 1 matches SARAH. The algorithm requires \( \Theta(ST) \) communication rounds. At each communication round, each worker computes large batch stochastic gradients and the server constructs \( v_{I(0,t,s)} \) by aggregating them. \( v_{I(0,t,s)} \) is used as an estimator of \( \nabla f(x_{I(0,t,s)}) \) to reduce computational cost. In line 14-21, we randomly select worker \( p_{t,s} \) and only worker \( p_{t,s} \) runs local optimization as described above. In the local optimization, we use SARAH like bias variance reduced estimator (line 16-18) rather than SVRG one and add noise (line 20) at each local update.

4 Convergence Analysis

In this section, we provide convergence theory of BVR-L-PSGD (Algorithm 1). All the omitted proofs are found in the supplementary material. For simple presentations, we use \( \Theta \) symbol to hide an extra poly-logarithmic factors that depend on \( L, \rho, G, K, b, T, S, 1/\varepsilon, 1/q \), where \( q \) represents the confidence parameter in high probability bounds.

4.1 Finding First-Order Stationary Points

First, we derive Descent Lemma for BVR-L-PSGD and first-order optimality guarantees by using it.

**Proposition 4.1** (Descent Lemma). Let \( S \in \mathbb{N} \) and \( I(k, t, s) \supseteq I(k_0, t_0, s_0) \subseteq [KTS] \cup \{0\} \). Suppose that Assumptions 1, 2, 3 and 5 hold. Given \( q \in (0, 1) \), \( r > 0 \), if we appropriately choose \( \eta = \Theta(1/L \wedge 1/(K\zeta) \wedge \sqrt{b/K\zeta} \wedge \sqrt{Pb}/(\sqrt{KTL})) \), it holds that

\[
f(x_{I(k,t,s)}) \leq f(x_{I(k_0,t_0,s_0)}) - \frac{\eta}{2} \sum_{i=I(k_0,t_0,s_0)}^{I(k,t,s)-1} \| \nabla f(x_i) \|^2 + \eta \Delta_T r^2 + R_1
\]

with probability at least \( 1 - 3q \). Here, \( \Delta_T := I(k, t, s) - I(k_0, t_0, s_0) \),

\[
R_1 := - \frac{1}{\eta} \sum_{i=I(k_0,t_0,s_0)}^{I(k,t,s)-1} \| x_{i+1} - x_i \|^2 + \frac{c_\eta}{\eta} r^2 \sum_{i=I(0,t_0,s_0)}^{I(k_0,t_0,s_0)-1} \| x_{i+1} - x_i \|^2 + \frac{\Delta_T \sqrt{KTL}}{\sqrt{K}} \sum_{i=I(0,t_0,s_0)}^{I(k_0,t_0,s_0)-1} \| x_{i+1} - x_i \|^2 \text{ for some universal constant } c_\eta > 0.
\]
From Proposition 4.1 with \(I(k_0, t_0, s_0) \leftarrow 0\) and \(I(k, t, s) \leftarrow KTS\) gives the following corollary.

**Corollary 4.2.** Suppose that Assumptions 1, 2, 3, 4 and 5 hold. Under the same setting as in Proposition 4.3 and \(S \geq \Theta\left(\frac{(f(x_0) - f(x_*) - (\nabla f(x_0) - \nabla f(x_*)))}{(\eta KT)^2}\right)\), with probability at least \(1 - 3q\), there exists \(i \in [KTS + 1] \cup \{0\}\) such that \(\|\nabla f(x_i)\| \leq \epsilon\).

**Remark** (Communication complexity). The total number of communication rounds \(\Theta(TS)\) becomes \(\tilde{O}\left(T + \left(L/K + \zeta + L/\sqrt{KB} + \sqrt{TL/\sqrt{KB}}\right) (f(x_0) - f(x_*))/\epsilon^2\right)\). Given local computation budget \(B\), we set \(T := \Theta(1 + n/(BP))\) and \(KB := \Theta(B)\) with \(b \leq \Theta(\sqrt{B})\). Then, we have the averaged number of local computations per communication round \(Kb + n/(PT) = \Theta(B)\) and the communication complexity \(TS\) with budget \(B\) becomes

\[
\tilde{O}\left(1 + \frac{n}{BP} + \frac{1}{\sqrt{K\epsilon^2}} + \frac{\sqrt{P}}{\sqrt{K\epsilon}} + \frac{\epsilon}{\sqrt{\epsilon}}\right),
\]

which matches the best known communication complexity \(\Theta(\sqrt{n})\).

### 4.2 Escaping Saddle Points

Next, we show that BVR-L-PSGD implicitly exploits the negative curvature of \(f\) around saddle points and efficiently escapes the saddle points by utilizing the asymptotic consistency of BVR estimator and the parameter perturbation at each local update.

We rely on the technique of coupling sequence \([10]\). Given saddle point \(\tilde{x}_I(k_0, t_0, s_0)\) and \(\tilde{I} \geq I(k_0, t_0, s_0)\), we define a new sequence \(\{x'_i\}_{i=I(k_0, t_0, s_0)}^{\infty}\) as follows:

1. \(\langle \xi^j_I, e_{\min} \rangle = -\langle \xi^j_I, e_{\min} \rangle\); 2. \(\langle \xi^j_I, e_j \rangle = \langle \xi^j_I, e_j \rangle\) for \(j \in \{2, \ldots, d\}\); and 3. All the other randomness is completely same as the one of \(\{x_i\}^{KTS-1}\). Let \(r_0 := \|\langle \xi_I, e_{\min} \rangle\|\). Note that \(\|\xi_I - \xi^j_I, e_{\min}\| = 2r_0\) and thus \(\|\xi_I - \xi^j_I\| = 2r_0\). Also, observe that \(x_I+1-x'^j_{I+1} = \eta\langle \xi_I - \xi^j_I, e_{\min}\rangle e_{\min}\).

We define \(\tilde{I}\) used in the definition of coupling sequence as follows:

\[
\tilde{I} := \begin{cases} I(k_0, t_0, s_0), & (1/\etaK) \\ I(k_0', t_0, s_0) - 1, & (\sqrt{K} < 1/(\etaK)) \\ I(0, t_0 + 1, s_0) - 1, & (K < 1/(\etaK)) \\ I(0, 0, s_0 + 1) - 1, & (K < 1/(\etaK)) \\ I(0, 0, s_0), & 1/(\etaK) \leq \sqrt{K} \\ I(k_0', t_0, s_0), & (\sqrt{K} < 1/(\etaK)) \leq K \end{cases}
\]

Here, \(k_0'\) is the minimum index \(k > k_0\) and \(k \equiv 0 \pmod{\lceil \sqrt{K} \rceil}\). We can easily check that \(\tilde{I} - I(k_0, t_0, s_0) \leq 1/(\etaK)\).

Then, we show that either of the two sequences \(\{x_i\}\) or \(\{x'_i\}\) efficiently escapes the saddle points by bounding the norm of the cumulative difference of \(x_i\) and \(x'_i\) from below. The novel and most difficult part of the analysis is to evaluate the norm of the cumulative difference of the deviations \(\|\sum_{i=I}^{\tilde{I}}(1 - \etaH)\tilde{J}_i - v_i - \nabla f(x_i) - v'_i + \nabla f(x'_i))\|\) generated by the two sequences, where \(v'_i\) denotes the BVR estimator at iteration \(i\) generated by sequence \(x'_i\).

**Proposition 4.3** (Implicit Negative Curvature Exploitation). Let \(I(k_0, t_0, s_0) \in [KTS] \cup \{0\}\). Suppose that Assumptions 1, 2, 3, 4 and 5 hold. Suppose that Assumptions 1, 2, 3, 4 and 5 hold. Under the minimum eigenvalue \(\lambda_{\min} \in \mathcal{H} := \nabla f(\tilde{x}_I(k_0, t_0, s_0)) \) satisfies \(\lambda := -\lambda_{\min} > \sqrt{\epsilon}\). Under \(b = \Omega(K \vee 1/(\sqrt{K}\epsilon)) \vee T/(PK)\), if we appropriately choose \(\tilde{J}_I(k_0, t_0, s_0) = \tilde{\Theta}(1/(\eta\epsilon))\), \(\eta = \tilde{\Theta}(1/L \wedge 1/(K\zeta) \wedge \sqrt{B}/\sqrt{K} \wedge \sqrt{P}/(\sqrt{K}/L))\), with \(\mathcal{F}_I(k_0, t_0, s_0) := c_T\sqrt{\eta}\tilde{J}_I(k_0, t_0, s_0)^2\) and \(r = c_r\epsilon (c_T = \tilde{\Theta}(1)\) and \(c_r = \tilde{\Theta}(1))\) we have

\[
f(x_I(k_0, t_0, s_0) + \tilde{J}_I(k_0, t_0, s_0)) - f(x_I(k_0, t_0, s_0)) \leq -\mathcal{F}_I(k_0, t_0, s_0) + R_2
\]

with probability at least \(1/2 - 9\eta/2\). Here, \(R_2 := \frac{2c_T\tilde{J}_I(k_0, t_0, s_0)^{\wedge K}}{K^{\sqrt{T}}} \sum_{i=I(k_0, t_0, s_0)}^{I(k_0, t_0, s_0) - 1} \|x_{i+1} - x_i\| + \frac{2c_T\tilde{J}_I(k_0, t_0, s_0)^{\wedge K}}{K^{\sqrt{T}}} \sum_{i=I(k_0, t_0, s_0)}^{I(k_0, t_0, s_0) - 1} \|x_{i+1} - x_i\| \) for some universal constant \(c_T > 0\).

Proposition 4.3 says the function value decreases by roughly \(\mathcal{F}_I(k_0, t_0, s_0)\) and the global model escapes saddle points with probability at least \(1/2\) after \(\tilde{J}_I(k_0, t_0, s_0)\) local steps.
4.3 Finding Second-Order Stationary Points

In this subsection, we derive final theorem that guarantees the second-order optimality of the global model by combining Propositions 4.1 and 4.3.

**Theorem 4.4 (Final Theorem).** Suppose that Assumptions [7] [2] [2] and [3] hold. Under $b = \Omega(K \sqrt{1/(\sqrt{K} \rho \varepsilon)} + T/(PK))$, if we appropriately choose $\eta = \Theta(1/L \wedge 1/(K \zeta) \wedge \sqrt{b/\varepsilon} + \sqrt{\varepsilon}/L \wedge \sqrt{P_b/(K \varepsilon)})$, $r = \Theta(\varepsilon)$ and $S = \Theta(1 + (f(x_0) - f(x_1))/\eta)$, with probability at least $1/2$, there exists $i \in [KTS] \cup \{0\}$ such that $\tilde{x}_i$ is $\varepsilon$-second-order optimal point of $f$.

**Remark** (High probability bound). Theorem 4.4 guarantees that Algorithm 1 finds an approximate second-order optimal point in $KTS$ iterations with probability at least $1/2$. Repeating Algorithm 1 $\log_2(1/q)$ times guarantees that the same statement holds with probability at least $1 - q$.

**Remark** (Communication complexity). The total number of communication rounds $TS$ is given by $\tilde{O} \left( T + \left( L/K + \zeta + L/\sqrt{Kb} + \sqrt{T/\sqrt{K}P_b} \right) \left( f(x_0) - f(x_1) \right)/\varepsilon^2 \right)$. Given local computation budget $B$, we set $T := \Theta(1 + n/(BP))$ and $Kb := \Theta(B)$ with $b \leq \Theta(\sqrt{B})$. Then, we have the averaged number of local computations per communication round $Kb + n/(PT) = \Theta(B)$ and the communication complexity $\Theta(TS)$ with budget $B$ becomes

$$\tilde{O} \left( 1 + \frac{n}{BP} + \frac{L}{B \varepsilon^2} + \frac{\sqrt{T}}{B \varepsilon^{3/2}} + \frac{\zeta}{\varepsilon^2} \right).$$

This implies that for $\zeta = o(L)$ the communication complexity is strictly smaller than the one of minbatch SGD $\tilde{O} \left( 1 + L/\varepsilon^2 + G^2/(BP\varepsilon^4) \right)$. Note that the rate matches to the one of BVR-L-SGD [20]. Hence, our method finds second-order optimal points without hurting communication efficiency of the state-of-the-art first-order optimality guaranteed method. Furthermore, when $B \to \infty$, we have $\Theta(1 + \zeta/\varepsilon^2)$, that goes to $\Theta(1)$ as $\zeta \to 0$.

In summary, BVR-L-PSGD enjoys the desirable properties (i) and (ii) described in Section 1.

5 Numerical Results

In this section, we give some experimental results to verify our theoretical findings.

**Data Preparation.** We artificially generated heterogeneous local datasets from CIFAR10 dataset. The data preparation procedure is completely in accordance with [20] and the details are found in [20]. We set homogeneity parameter $q$ to 0.35, which captures how similar the local datasets are ($q = 0.1$ corresponds to I.I.D. case and higher $q$ does to higher heterogeneity).

**Model.** We conducted our experiments using a two-hidden layers fully connected neural network with 100 hidden units and softplus activation. For loss function, we used the standard cross-entropy loss. We initialized parameters by uniformly sampling the parameters from $[-1/100, 1/100]$.

**Implemented Algorithms.** Minibatch SGD, Noisy Minibatch SGD, BVR-L-SGD [20] and our proposed BVR-L-PSGD were implemented. We set $K = 64$ and $b = 16$, and thus $B = 1024$. For BVR-L-PSGD, the noise radius was tuned from $r \in \{0.5, 2.5, 12.5\}$. For each algorithm, we tuned learning rate $\eta$ from $\{0.005, 0.01, 0.05, 0.1, 0.5, 1.0\}$. The details of the tuning procedure are found in the supplementary material.

**Evaluation.** We compared the implemented algorithms using six criteria of train gradient norm $\|\nabla f(x)\|$; train loss; train accuracy; test gradient norm; test loss and test accuracy against the number of communication rounds. The total number of communication rounds was fixed to 1,000 for each algorithm. We independently repeated the experiments 5 times and report the mean and standard deviation of the above criteria. Due to the space limitation, we will only report train gradient norm, train loss and test accuracy in the main paper. The full results are found in the supplementary material.

**Results.** Figure 1 shows the performances of BVR-L-SGD and our proposed algorithm. We can

---

6One limitation of Theorem 4.4 is that it only guarantees the existence of $\varepsilon$-second-order optimal point $\tilde{x}$, in the history of $\{\tilde{x}_i\}_{i=0}^{KTS+1}$. However, this is also the case in the existing studies [25] [18]. We empirically found that the outputs of each communication rounds showed stable performances (see Section 5).

https://www.cs.toronto.edu/~kriz/cifar.html
see that the both algorithms got stuck at a small gradient norm region in initial rounds. After that BVR-L-SGD showed unstable convergence and took a lot of time to escape the stucked region. In contrast, our proposed method efficiently escaped the stucked region and consistently achieves better train loss and test accuracy than BVR-L-SGD. Also, our method consistently outperformed Minibatch SGD and Noisy Minibatch SGD.

6 Conclusion

In this paper, we have studied a new local algorithm called Bias-Variance Reduced Local Perturbed SGD (BVR-L-PSGD) based on a combination of the bias-variance reduced gradient estimator with parameter perturbation to efficiently find second-order optimal points in centralized nonconvex distributed optimization. We have shown that BVR-L-PSGD enjoys second-order optimality without hurting the best known communication complexity for first-order optimality guarantees. Particularly, the communication complexity is better than non-local methods when Hessian heterogeneity $\xi$ of local datasets is smaller than the smoothness of the local loss $L$ in order sense. Also, for sufficiently large $B$, the communication complexity of our method approaches to $\Theta(1)$ when the local datasets heterogeneity $\xi$ goes to zero. The numerical results have validated our theoretical findings.

A Supplementary Material for Numerical Results

In this section, we give additional information and numerical results that complement the contents in Section 5.

Parameter Tuning

For the implemented algorithms, learning rate \( \eta \) was tuned. Also, for Noisy Minibatch SGD and BVR-L-PSGD, noise radius \( r \) was also tuned. We ran each algorithm for all the patterns of the tuning parameters and chose the ones that maximized the minimum train accuracy.

Additional Numerical Results

Here, we provide the full results of our numerical experiments. Figures 2 and 3 show the comparisons of the six criterion, i.e., train gradient norm, train loss, train accuracy, test gradient norm, test loss and test accuracy with fixed local computation budget \( B = 1,024 \) under \( q = 0.1 \) (I.I.D. case) and \( q = 0.35 \) (heterogeneous case) respectively.

B Convergence Analysis

In this section, complete analysis of BVR-L-PSGD is provided. Particularly, detailed proofs of Proposition 4.1, Corollary 4.2 (Subsection B.3), Proposition 4.3 (Subsection B.4) and Theorem 4.4 (Subsection B.5) are given.

B.1 Miscellaneous Results

Lemma B.1. Let $A \in \mathbb{R}^{d \times d}$ with the smallest and largest eigenvalues $\lambda_{\min} \in (-\infty, 0)$ and $\lambda_{\max} \in [0,1)$ respectively. Then, for $J \in \mathbb{N} \cup \{0\}$, it holds that

$$\|A(1-A)^J\| \leq (-\lambda_{\min})(1-\lambda_{\min})^J + \frac{e}{J+1}.$$ 

Proof. First, when $J = 0$, trivially $\|A(1-A)^J\| \leq \max\{-\lambda_{\min}, \lambda_{\max}\} < (-\lambda_{\min}) + e$. Thus, we assume $J > 0$. Note that $\|A(1-A)^J\| = \sup_{\sigma \in [\lambda_{\min}, \lambda_{\max}]} |\sigma(1-\sigma)^J|$. We consider the two cases $\sigma \in [\lambda_{\min}, 0)$ and $\sigma \in [0, \lambda_{\max}]$.

In the former case, $h(\sigma) := |\sigma(1-\sigma)^J| = -\sigma(1-\sigma)^J$ is monotonically decreasing function on $(-\infty, 0)$ because the derivative function $h'(\sigma) = -(1-\sigma)^J + J(1-\sigma)^{J-1} = (1-\sigma)^{J-1}(J+1)\sigma - 1 < 0$, and hence $\sup_{\sigma \in [\lambda_{\min}, 0)} h(\sigma) \leq (-\lambda_{\min})(1-\lambda_{\min})^J$.

In the latter case, $h(\sigma) = \sigma(1-\sigma)^J$ has the derivative function $h'(\sigma) = (1-\sigma)^J - J(1-\sigma)^{J-1} = (1-\sigma)^{J-1}(1-(J+1)\sigma)$, thus, it holds that $h'(1/(J+1)) = 0$, $h'(\sigma) > 0$ for $\sigma \in [0,1/(J+1))$ and $h'(\sigma) < 0$ for $\sigma \in (1/(J+1), 1]$. Hence, for $\sigma \in [0, \lambda_{\max}]$ with $\lambda_{\max} \in [0,1)$, $h(\sigma) \leq h(1/(J+1)) \leq e/(J+1)$.

In summary, we have shown that $\sup_{\sigma \in [\lambda_{\min}, \lambda_{\max}]} h(\sigma) \leq (-\lambda_{\min})(1-\lambda_{\min})^J + e/(J+1)$. This is the desired result. \qed

B.2 Concentration Inequalities

Lemma B.2 (Corollary 8 in [9]). Let $X_1, \ldots, X_n$ be random vectors in $\mathbb{R}^d$. Suppose that $\{X_i\}_{i=1}^n$ and corresponding filtrations $\{\mathcal{F}_i\}_{i=1}^n$ satisfy the following conditions:

$$\mathbb{E}[X_i | \mathcal{F}_{i-1}] = 0 \text{ and } \mathbb{P}(\|X_i\| \geq s | \mathcal{F}_{i-1}) \leq 2e^{-\frac{s^2}{2\sigma_i^2}}, \forall s \in \mathbb{R}, \forall i \in [n]$$

for random variables $\{\sigma_i\}_{i=1}^n$ with $\sigma_i \in \mathcal{F}_{i-1}$ ($i \in [n]$). Then, for any $q \in (0,1)$ and $A > a > 0$, with probability at least $1-q$ it holds that

$$\sum_{i=1}^n \sigma_i^2 \geq A \text{ or } \left\|\sum_{i=1}^n X_i\right\| \leq c \max\left\{\sum_{i=1}^n \sigma_i^2, a\right\} \left(\frac{\log \frac{2d}{q} + \log \log \frac{A}{a}}{a}\right)$$

for some constant $c > 0$.

Note that if $X$ is bounded and centered random vector, i.e., $\|X\| \leq \sigma$ a.s. and $\mathbb{E}[X] = 0$, it holds that $\mathbb{P}(\|X\| \geq s) \leq 2e^{-s^2/2\sigma^2}$ for every $s \in \mathbb{R}$. Hence, $\|X_i\| \leq \sigma_i^2$ a.s. and $\mathbb{E}[X_i] = 0$ conditioned on $\mathcal{F}_{i-1}$ is a sufficient condition for applying Lemma B.2.

B.3 Finding First-Order Stationary Points

Proof of Proposition 4.1

We fix $k \in [K] \cup \{0\}$, $t \in [T - 1] \cup \{0\}$ and $s \in [S - 1] \cup \{0\}$. From $L$-smoothness of $f$, we have

$$f(x_{I(k+1,t,s)}) \leq f(x_{I(t,s)}) + \langle \nabla f(x_{I(t,s)}), x_{I(k+1,t,s)} - x_{I(t,s)} \rangle + \frac{L}{2}\|x_{I(k+1,t,s)} - x_{I(t,s)}\|^2.$$
From this inequality, we have

\[
f(x_{I(k,t,s)}) \leq f(x_{I(k,t,s)}) + \langle \nabla f(x_{I(k,t,s)}) - v_{I(k,t,s)} + \xi_{I(k,t,s)}, x_{I(k+1,t,s)} - x_{I(k,t,s)} \rangle \\
+ \langle v_{I(k,t,s)} - \xi_{I(k,t,s)}, x_{I(k+1,t,s)} - x_{I(k,t,s)} \rangle + \frac{L}{2} \|x_{I(k+1,t,s)} - x_{I(k,t,s)}\|^2 \\
= f(x_{I(k,t,s)}) + \langle \nabla f(x_{I(k,t,s)}), -\frac{L}{2} \|x_{I(k+1,t,s)} - x_{I(k,t,s)}\|^2 \rangle \\
- \left( \frac{1}{\eta} - \frac{L}{2} \right) \|x_{I(k+1,t,s)} - x_{I(k,t,s)}\|^2 \\
= f(x_{I(k,t,s)}) + \eta \|v_{I(k,t,s)} - \xi_{I(k,t,s)} - \nabla f(x_{I(k,t,s)})\|^2 - \frac{\eta}{2} \|\nabla f(x_{I(k,t,s)})\|^2 \\
+ \frac{1}{2\eta} \|x_{I(k+1,t,s)} - x_{I(k,t,s)}\|^2 - \left( \frac{1}{\eta} - \frac{L}{2} \right) \|x_{I(k+1,t,s)} - x_{I(k,t,s)}\|^2 \\
= f(x_{I(k,t,s)}) + \eta \|v_{I(k,t,s)} - \xi_{I(k,t,s)} - \nabla f(x_{I(k,t,s)})\|^2 - \frac{\eta}{2} \|\nabla f(x_{I(k,t,s)})\|^2 \\
- \left( \frac{1}{2\eta} - \frac{L}{2} \right) \|x_{I(k+1,t,s)} - x_{I(k,t,s)}\|^2 \\
\leq f(x_{I(k,t,s)}) + \eta \|v_{I(k,t,s)} - \xi_{I(k,t,s)} - \nabla f(x_{I(k,t,s)})\|^2 - \frac{\eta}{2} \|\nabla f(x_{I(k,t,s)})\|^2 \\
- \left( \frac{1}{2\eta} - \frac{L}{2} \right) \|x_{I(k+1,t,s)} - x_{I(k,t,s)}\|^2 + \eta \|\xi_{I(k,t,s)}\|^2 \\
\leq f(x_{I(k,t,s)}) + \eta \|v_{I(k,t,s)} - \xi_{I(k,t,s)} - \nabla f(x_{I(k,t,s)})\|^2 - \frac{\eta}{2} \|\nabla f(x_{I(k,t,s)})\|^2 \\
- \left( \frac{1}{2\eta} - \frac{L}{2} \right) \|x_{I(k+1,t,s)} - x_{I(k,t,s)}\|^2 + \eta \|\xi_{I(k,t,s)}\|^2. \\
\tag{1}
\]

Here, for the first equality we used the fact \( v_{I(k,t,s)} - \xi_{I(k,t,s)} = -(1/\eta) (x_{I(k+1,t,s)} - x_{I(k,t,s)}) \). The second equality follows from the facts \( v_{I(k,t,s)} - \xi_{I(k,t,s)} = (1/\eta) (x_{I(k+1,t,s)} - x_{I(k,t,s)}) \) and \((a - b, -b) = (1/2)(\|a - b\|^2 - \|a\|^2 + \|b\|^2)\) for any \(a, b \in \mathbb{R}^d\). For the second inequality, we used the relation \(\|a + b\| \leq 2(\|a\|^2 + \|b\|^2)\) for any \(a, b \in \mathbb{R}^d\). The last inequality holds from the definition of \(\xi_{I(k,t,s)}\).

Thus, for every \(k, k_0 \in [K - 1], t, t_0 \in [T - 1]\) and \(s, s_0 \in [S - 1]\) \((I(k, t, s) \geq I(k_0, t_0, s_0))\), we have

\[
f(x_{I(k,t,s)}) \leq f(x_{I(k_0,t_0,s_0)}) + \eta \sum_{i=I(k_0,t_0,s_0)}^{I(k,t,s)-1} \|v_i - \nabla f(x_i)\|^2 \\
- \frac{\eta}{2} \sum_{i=I(k_0,t_0,s_0)}^{I(k,t,s)-1} \|\nabla f(x_i)\|^2 - \left( \frac{1}{2\eta} - \frac{L}{2} \right) \sum_{i=I(k_0,t_0,s_0)}^{I(k,t,s)-1} \|x_{i+1} - x_i\|^2 \\
+ \eta (I(k, t, s) - I(k_0, t_0, s_0)) v^2. \\
\tag{2}
\]
Now we bound the deviation $\|v_I(k,t,s) - \nabla f(x_I(k,t,s))\|^2$. Observe that

\[
v_I(k,t,s) - \nabla f(x_I(k,t,s)) = g_I(k,t,s) - g_I^{ref}(k,t,s) + v_I(k-1,t,s) - \nabla f(x_I(k,t,s))
\]

\[
= g_I(k,t,s) - g_I^{ref}(k,t,s) + \nabla f_{p_{k,\nu}}(x_I(k-1,t,s)) - \nabla f_{p_{k,\nu}}(x_I(k,t,s))
+ \nabla f_{p_{k,\nu}}(x_I(k,t,s)) - \nabla f_{p_{k,\nu}}(x_I(k-1,t,s)) + \nabla f(x_I(k-1,t,s)) - \nabla f(x_I(k,t,s))
+ v_I(k-1,t,s) - \nabla f(x_I(k-1,t,s))
\]

\[
= \sum_{k=0}^{k-1} (g_I(k+1,t,s) - g_I^{ref}(k+1,t,s) + \nabla f_{p_{k,\nu}}(x_I(k,t,s)) - \nabla f_{p_{k,\nu}}(x_I(k+1,t,s))
+ \nabla f_{p_{k,\nu}}(x_I(k+1,t,s)) - \nabla f_{p_{k,\nu}}(x_I(k,t,s)) + \nabla f(x_I(k,t,s)) - \nabla f(x_I(k+1,t,s))
+ v_I(0,t,s) - \nabla f(x_I(0,t,s)).
\]

Further, we have

\[
v_I(0,t,s) - \nabla f(x_I(0,t,s)) = \frac{1}{P} \sum_{p=0}^{P} (g_I(p,0,t,s) - g_I^{ref}(p,0,t,s) + v_I(0,t-1,s) - \nabla f(x_I(0,t,s))
\]

\[
= \frac{1}{P} \sum_{p=0}^{P} (g_I(p,0,t,s) - g_I^{ref}(p,0,t,s) + \nabla f(x_I(0,t-1,s)) - \nabla f(x_I(0,t,s))
+ v_I(0,t-1,s) - \nabla f(x_I(0,t-1,s))
\]

\[
= \sum_{\tau=0}^{t-1} \frac{1}{P} \sum_{p=0}^{P} (g_I(p,0,\tau+1,s) - g_I^{ref}(p,0,\tau+1,s) + \nabla f(x_I(0,\tau,s)) - \nabla f(x_I(0,\tau+1,s))
+ v_I(0,0,s) - \nabla f(x_I(0,0,s)).
\]

Note that the last term is exactly zero from the definition of $v_I(0,0,s)$.

We define

\[
\alpha_I(k,t,s) := g_I(k,t,s) - g_I^{ref}(k,t,s) + \nabla f_{p_{k,\nu}}(x_I(k-1,t,s)) - \nabla f_{p_{k,\nu}}(x_I(k,t,s))
\]

\[
\beta_I(k,t,s) := \nabla f_{p_{k,\nu}}(x_I(k-1,t,s)) - \nabla f_{p_{k,\nu}}(x_I(k-1,t,s)) + \nabla f(x_I(k-1,t,s)) - \nabla f(x_I(k,t,s))
\]

\[
\gamma_I(0,\tau,s) := \frac{1}{P} \sum_{p=1}^{P} (g_I(p,0,\tau,s) - g_I^{ref}(p,0,\tau,s) + \nabla f(x_I(0,\tau-1,s)) - \nabla f(x_I(0,\tau,s))
\]

and

\[
\begin{aligned}
A_I(k,t,s) &:= \sum_{k=0}^{k-1} \alpha_I(k+1,t,s), \\
B_I(k,t,s) &:= \sum_{\tau=0}^{\ell-1} \beta_I(k+1,t,s), \\
C_I(0,t,s) &:= \sum_{\tau=0}^{\ell-1} \gamma_I(0,\tau+1,s).
\end{aligned}
\]

Note that $\mathbb{E}[A_I(k,t,s)] = \mathbb{E}[C_I(k,t,s)] = 0$. Using these definitions, we have

\[
\|v_I(k,t,s) - \nabla f(x_I(k,t,s))\|^2 \leq 3(\|A_I(k,t,s)\|^2 + \|B_I(k,t,s)\|^2 + \|C_I(k,t,s)\|^2).
\]

We denote all the randomness up to iteration $I(k-1,t,s)$ as $\mathcal{F}_{I(k-1,t,s)}$.

Bounding $\|A_I(k,t,s)\|$  

Let $\alpha_I(k,t,s) := \nabla f(x_I(k,t,s)), \mathcal{Z}_{I(k,t,s)} - \nabla f(x_I(k-1,t,s)), \mathcal{Z}_{I(k,t,s)} + \nabla f_{p_{k,\nu}}(x_I(k-1,t,s)) + \nabla f_{p_{k,\nu}}(x_I(k,t,s))$. Then, $\alpha_I(k,t,s) = (1/b) \sum_{l=1}^{b} \alpha_I(l,k,t,s)$. Observe that $\alpha_I(k,t,s)$ satisfies

\[
\mathbb{E}[\alpha_I(k,t,s) | \mathcal{F}_{I(k-1,t,s)}] = 0
\]

and

\[
P(\|\alpha_I(k,t,s)\| \geq s | \mathcal{F}_{I(k-1,t,s)}) \leq 2e^{-\frac{s^2}{2(\sigma^2_{\mathcal{F}_{I(k-1,t,s)})}}}
\]
for every \( s \in \mathbb{R} \) and \( \kappa \in [k] \), where \( \sigma_{I(\kappa,t,s)}^{(\alpha)} := 2L\|x_{I(\kappa,t,s)} - x_{I(\kappa-1,t,s)}\| \). Here, we used the fact that \( \|\nabla \ell(x_{I(\kappa,t,s)}, z_{I(\kappa,t,s)}) - \nabla \ell(x_{I(\kappa-1,t,s)}, z_{I(\kappa,t,s)}) + \nabla f_{P_{t,s}}(x_{I(\kappa-1,t,s)})\| \leq 2L\|x_{I(\kappa,t,s)} - x_{I(\kappa-1,t,s)}\| \) from \( L \)-smoothness of \( \ell \). Note that \( \{a_{I(\kappa,t,s)}\}_{k=1}^{Kb} \) is i.i.d. sequence with at least \( b \) samples and \( \|a_{\kappa, I(\kappa,t,s)}\| \leq 4G \) almost surely from Assumption~5.

From these results, we can use Lemma~B.2 with \( A = 4KG \) and \( a = \varepsilon (\varepsilon \) is some positive number and will be defined later) and get

\[
\|A_{I(k,t,s)}\|^2 \leq \frac{c^2}{b} \left( \sum_{\kappa=0}^{k-1} \left( \sigma_{I(\kappa+1,t,s)}^{(\alpha)} \right)^2 \right) + \varepsilon \left( \log \frac{2d}{q} + \log \log \frac{4KG}{\varepsilon} \right)
\]

with probability at least \( 1 - q \) for some constant \( c > 0 \). Also, note that \( \|A_{I(k,t,s)}\| \leq 4kG \) almost surely.

### Bounding \( \|B_{I(k,t,s)}\| \)

Observe that

\[
\beta_{I(\kappa,t,s)} = \nabla f_{P_{t,s}}(x_{I(\kappa,t,s)}) - \nabla f_{P_{t,s}}(x_{I(\kappa-1,t,s)}) + \nabla f(x_{I(\kappa-1,t,s)}) - \nabla f(x_{I(\kappa,t,s)})
\]

\[
= (\nabla f_{P_{t,s}} - \nabla f)(x_{I(\kappa,t,s)}) - (\nabla f_{P_{t,s}} - \nabla f)(x_{I(\kappa-1,t,s)})
\]

\[
= \left( \int_{0}^{1} (\nabla^2 f_{P_{t,s}} - \nabla^2 f)(\theta x_{I(\kappa,t,s)} + (1 - \theta)x_{I(\kappa-1,t,s)})d\theta \right) (x_{I(\kappa,t,s)} - x_{I(\kappa-1,t,s)}).
\]

Hence, from Assumption~1, we get

\[
\|\beta_{I(\kappa,t,s)}\| \leq \zeta \|x_{I(\kappa,t,s)} - x_{I(\kappa-1,t,s)}\| =: \sigma_{I(\kappa,t,s)}^{(\beta)}.
\]

This gives

\[
\|B_{I(k,t,s)}\|^2 \leq k \sum_{\kappa=0}^{k-1} \left( \sigma_{I(\kappa+1,t,s)}^{(\beta)} \right)^2.
\]

Here we used the relation \( (\sum_{i=0}^{m} |a_i|)^2 \leq m \sum_{i=0}^{m} a_i^2 \) for every \( \{a_i\}_{i=1}^{m} \subset \mathbb{R} \). Also, note that \( \|B_{I(k,t,s)}\| \leq 4kG \) almost surely.

### Bounding \( \|C_{I(0,t,s)}\| \)

The argument is similar to the one of the case of the first term. From Lemma~B.2, the third term \( \|C_{I(0,t,s)}\| \) can be bounded as

\[
\|C_{I(0,t,s)}\|^2 \leq \frac{c^2}{PKb} \left( \sum_{\tau=0}^{t-1} \left( \sigma_{I(\tau+1,t,s)}^{(\gamma)} \right)^2 \right) + \varepsilon \left( \log \frac{2d}{q} + \log \log \frac{4KTG}{\varepsilon} \right),
\]

with probability at least \( 1 - q \), where \( \sigma_{I(0,t,s)}^{(\gamma)} := 2L \sum_{\tau=0}^{K-1} \|x_{I(\tau+1,t-1,s)} - x_{I(\tau-1,t-1,s)}\| \geq 2L\|x_{I(0,t-1,s)} - x_{I(0,t-1,s)}\| \). Here, we used the fact that \( \{g^{(p)}_{I(\tau,s)} - g^{(p)}_{I(\tau,s)}\}_{p=1}^{Kb} \) is independent and each of them is constructed from \( Kb \) i.i.d. data samples. Also, note that \( \|C_{I(k,t,s)}\| \leq 4TG \) almost surely.

Put the three results all together, we obtain

\[
\|v_{I(k,t,s)} - \nabla f(x_{I(k,t,s)})\|^2 \leq \frac{3c^2}{b} \left( \sum_{\kappa=0}^{k-1} \left( \sigma_{I(\kappa+1,t,s)}^{(\alpha)} \right)^2 \right) + \varepsilon \left( \log \frac{2KTSd}{q} + \log \log \frac{4KG}{\varepsilon} \right)
\]

\[
+ 3k \sum_{\kappa=0}^{k-1} \left( \sigma_{I(\kappa+1,t,s)}^{(\beta)} \right)^2
\]

\[
+ \frac{3c^2}{PKb} \left( \sum_{\tau=0}^{t-1} \left( \sigma_{I(\tau+1,t,s)}^{(\gamma)} \right)^2 \right) + \varepsilon \left( \log \frac{2KTSd}{q} + \log \log \frac{4TG}{\varepsilon} \right)
\]
for every $k \in [K-1]$, $t \in [T-1]$ and $s \in [S-1]$ with probability at least $1 - 3q$ for some constant $c > 0$. We set $q \leftarrow q/(KTS)$. Now, we set

$$6e^2\epsilon \left( \log \frac{2KTSd}{q} + \log \log \frac{4KGTG}{\varepsilon} \right) \leq r^2.$$ 

Then, we have

$$\|v_I(k,t,s) - \nabla f(x_I(k,t,s))\|^2 \leq \frac{3e^2}{b} \left( k - 1 \right) \left( \sigma^2_{i(\alpha)}(k) \right) \left( \log \frac{2KTSd}{q} + \log \log \frac{G}{\varepsilon} \right)$$

$$+ 3k \left( \sum_{s=0}^{k-1} \left( \sigma^2_{i(\beta)}(k+1,t,s) \right) \right)^2$$

$$+ \frac{3e^2}{Pkb} \left( \sum_{s=0}^{t-1} \left( \sigma^2_{i(\gamma)}(0,t+1,s) \right) \right) \left( \log \frac{2KTSd}{q} + \log \log \frac{G}{\varepsilon} \right)$$

$$+ r^2$$

for every $I(k,t,s) \in [KTS] \cup \{0\}$.

Let

$$V(k,t,s) := 12e^2 \left( \frac{L^2}{b} + K\zeta^2 + \frac{L^2T}{Pb} \right) \left( \sum_{s=0}^{k-1} \|x_{I(k+1,t,s)} - x_I(k,t,s)\|^2 \right)$$

$$+ \frac{1}{T} \sum_{s=0}^{t-1} \sum_{k=0}^{K-1} \|x_{I(k+1,t,s)} - x_{I(k,t,s)}\|^2$$

$$\times \left( \log \frac{2KTSd}{q} + \log \log \frac{4KGTG}{\varepsilon} \right).$$

Observe that $\|v_I(k,t,s) - \nabla f(x_I(k,t,s))\|^2 \leq V(k,t,s) + r^2$ and $V(k,t,s) \leq V(k',t',s)$ for $k' \geq k$ and $t' \geq t$.

Now, we bound $\sum_{i=I(k,t,s)}^{I(k,t,s)} \|v_i - \nabla f(x_i)\|^2$ by dividing three cases.

**Case I.** $s = s_0$ and $t = t_0$.

We bound $\sum_{i=I(k,t,s)}^{I(k,t,s)} \|v_i - \nabla f(x_i)\|^2$ for general $k_-, t_-$ and $s_-$ with $k_- \leq k$, $t_- = t$ and $s_- = s$.

$$\sum_{i=I(k,t,s)}^{I(k,t,s)} \|v_i - \nabla f(x_i)\|^2$$

$$\leq \sum_{k'=k_-}^{k} V(k',t_-,s_-) + (k - k_- + 1)r^2$$

$$\leq (k - k_- + 1)V(k,t_-,s_-) + (k - k_- + 1)r^2$$

$$\leq 12e^2 \left( \frac{KL^2}{b} + K^2\zeta^2 + \frac{KL^2T}{Pb} \right)$$

$$\times \left( \frac{k - k_- + 1}{K} \sum_{k=0}^{k-1} \|x_{I(k+1,t-,s_-)} - x_{I(k,t-,s_-)}\|^2 \right)$$

$$+ \frac{k - k_- + 1}{KT} \sum_{k=0}^{t-1} \sum_{k=0}^{K-1} \|x_{I(k+1,t-,s_-)} - x_{I(k,t-,s_-)}\|^2$$

$$\times \left( \log \frac{2KTSd}{q} + \log \log \frac{4KGTG}{\varepsilon} \right)$$

$$+ (k - k_- + 1)r^2.$$
Since

\[
\frac{k - k_-}{K} + \sum_{\kappa=0}^{k-1} \left( \|x_{I(k+1,t-,s_-)} - x_{I(k,t-,s_-)}\|^2 + \frac{k - k_- + 1}{K} \sum_{\tau=0}^{t_- - 1} \sum_{\kappa=0}^{K-1} \|x_{I(k+1,\tau,s_-)} - x_{I(k,\tau,s_-)}\|^2 \right)
\]

\[
\leq \sum_{\kappa=k_-}^{k-1} \left( \|x_{I(k+1,t-,s_-)} - x_{I(k,t-,s_-)}\|^2 + \frac{k - k_- + 1}{K} \sum_{\tau=0}^{k_- - 1} \sum_{\kappa=0}^{K-1} \|x_{I(k+1,\tau,s_-)} - x_{I(k,\tau,s_-)}\|^2 \right)
\]

\[
+ \frac{k - k_- + 1}{K} \sum_{\tau=0}^{t_- - 1} \sum_{\kappa=0}^{K-1} \|x_{I(k+1,\tau,s_-)} - x_{I(k,\tau,s_-)}\|^2
\]

\[
= \sum_{i=I(k_-,t_-)}^{I(k,t-,s_-)-1} \|x_{i+1} - x_i\|^2 + \frac{(I(k,t,s) - I(k-, t-, s_-) + 1) \wedge K I(k-, t-, s_-) - 1}{K} \sum_{i=I(0,t-,s_-)}^{I(k-, t-, s_-) - 1} \|x_{i+1} - x_i\|^2
\]

\[
+ \frac{(I(k,t-, s_-) - I(k-, t-, s_-) + 1) \wedge KT I(0,t-,s_-) - 1}{KT} \sum_{i=I(0,0,s_-)}^{I(0,t-,s_-) - 1} \|x_{i+1} - x_i\|^2,
\]

we get

\[
\sum_{i=I(k_-,t-,s_-)}^{I(k,t-,s_-) - 1} \|v_i - \nabla f(x_i)\|^2 \leq 12b^2 \left( \frac{KL^2}{b} + K^2 \xi^2 + \frac{KL^2 T}{b} \right)
\]

\[
\times \left( \sum_{i=I(k_-,t-,s_-)}^{I(k,t-,s_-) - 1} \|x_{i+1} - x_i\|^2 + \frac{(I(k,t-, s_-) - I(k-, t-, s_-) + 1) \wedge K I(k-, t-, s_-) - 1}{K} \sum_{i=I(0,t-,s_-)}^{I(k-, t-, s_-) - 1} \|x_{i+1} - x_i\|^2 \right)
\]

\[
+ \frac{(I(k,t-, s_-) - I(k-, t-, s_-) + 1) \wedge KT I(0,t-,s_-) - 1}{KT} \sum_{i=I(0,0,s_-)}^{I(0,t-,s_-) - 1} \|x_{i+1} - x_i\|^2
\]

\[
\times \left( \log \frac{2KT Sd}{q} + \log \log \frac{4KT G}{\xi} \right)
\]

\[
+ (I(k,t-, s_-) - I(k-, t-, s_-) + 1) r^2.
\]

Setting \(k_- \leftarrow k_0, t_- \leftarrow t_0\) and \(s_- \leftarrow s_0\) gives the desired bound.

**Case II.** \(s = s_0\) and \(t > t_0\).

Note that \(I(k,t,s_0) - I(k_0,t_0,s_0) \geq K\). Again, we consider \(\sum_{i=I(k_-,t-,s_-)}^{I(k,t,s_-)} \|v_i - \nabla f(x_i)\|^2\) for general \(k_-, t_-\) and \(s_-\) with \(k \geq k_-, t > t_-\) and \(s = s_-\).

\[
\sum_{i=I(k_-,t-,s_-)}^{I(k,t,s_-)} \|v_i - \nabla f(x_i)\|^2 \leq \sum_{i=I(k_-,t-,s_-)}^{I(K-1,t-,s_-)} \|v_i - \nabla f(x_i)\|^2 + \sum_{t'=t_-+1}^{t} \sum_{i=I(0,t',s_-)}^{I(K-1,t',s_-)} \|v_i - \nabla f(x_i)\|^2 + \sum_{i=I(0,t,s_-)}^{I(K,t,s_-)} \|v_i - \nabla f(x_i)\|^2.
\]
Using the result of Case I, the first term can be bounded as follows:

\[
\sum_{i=I_{(k_-,t_-,s_-)^{t-1}}} \|v_i - \nabla f(x_i)\|^2 \\
\leq 12c^2 \left( \frac{KL^2}{b} + K^2c^2 + \frac{KL^2T}{Pb} \right) \\
\times \left( \sum_{i=I_{(k_-,t_-,s_-)^{t-1}}} \|x_{i+1} - x_i\|^2 + \left( I(K - 1, t_-, s_-) - I(k_-, t_-, s_-) + 1 \right) \right) \\
\times \frac{I(K - 1, t_-, s_-) - I(0, t_-, s_-) + 1) \wedge K}{KT} \\
\sum_{i=I_{(0,0,s_-)^{t-1}}} \|x_{i+1} - x_i\|^2 \\
+ \frac{I(0, t_-, s_-) - I(k_-, t_-, s_-) + 1) \wedge K}{KT} \\
\sum_{i=I_{(0,0,s_-)^{t-1}}} \|x_{i+1} - x_i\|^2 \\
\times \left( \log \frac{2KTSd}{q} + \log \log \frac{4KTG}{\xi} \right) \\
+ (I(K - 1, t_-, s_-) - I(k_-, t_-, s_-) + 1) r^2.
\]

Similarly, the second term can be bounded as:

\[
\sum_{t'=t_- + 1}^{t-1} \sum_{i=I_{(0,t',s_-)^{t-1}}} \|v_i - \nabla f(x_i)\|^2 \\
\leq 12c^2 \left( \frac{KL^2}{b} + K^2c^2 + \frac{KL^2T}{Pb} \right) \\
\times \left( \sum_{t'=t_- + 1}^{t-1} \sum_{i=I_{(0,t',s_-)^{t-1}}} \|x_{i+1} - x_i\|^2 \\
+ \frac{I(K - 1, t', s_-) - I(0, t', s_-) + 1) \wedge K}{KT} \\
\sum_{i=I_{(0,0,s_-)^{t-1}}} \|x_{i+1} - x_i\|^2 \\
\times \left( \log \frac{2KTSd}{q} + \log \log \frac{4KTG}{\xi} \right) \\
\leq 12c^2 \left( \frac{KL^2}{b} + K^2c^2 + \frac{KL^2T}{Pb} \right) \\
\times \left( \sum_{i=I_{(0,t_- + 1,s_-)^{t-1}}} \|x_{i+1} - x_i\|^2 + \sum_{t'=t_- + 1}^{t-1} \frac{I(K - 1, t', s_-) - I(0, t', s_-) + 1) \wedge K}{KT} \\
\sum_{i=I_{(0,t_- + 1,s_-)^{t-1}}} \|x_{i+1} - x_i\|^2 \\
+ \frac{I(K - 1, t_- + 1, s_-) - I(0, t_- + 1, s_-) + 1) \wedge K}{KT} \\
\sum_{i=I_{(0,0,s_-)^{t-1}}} \|x_{i+1} - x_i\|^2 \\
\times \left( \log \frac{2KTSd}{q} + \log \log \frac{4KTG}{\xi} \right) \\
+ (I(K - 1, t_- + 1, s_-) - I(0, t_- + 1, s_-) + 1) r^2.
\]
Now, we bound the second term as follows:

\[
\sum_{t'=t-1}^{t-1} \frac{(I(K-1, t', s_-) - I(0, t', s_-) + 1) \land KT}{KT} I_{t-1}^{(0, t', s_-)} \sum_{i=I(0, t', s_-)}^{I_{t-1}^{(0, t', s_-)}} \|x_{i+1} - x_i\|^2 
\leq \frac{(I(K-1, t_- + 1, s_-) - I(0, t_- + 1, s_-) + 1) \land KT}{KT} I_{t-1}^{(k, t_-, s_-)} \sum_{i=I(0, t_-, s_-)}^{I_{t-1}^{(k, t_-, s_-)}} \|x_{i+1} - x_i\|^2 + \sum_{i=I(k, t_-, s_-)}^{I_{t-1}^{(k, t_-, s_-)}} \|x_{i+1} - x_i\|^2 
\leq \frac{(I(K-1, t_- + 1, s_-) - I(0, t_- + 1, s_-) + 1) \land KT}{KT} I_{t-1}^{(k, t_-, s_-)} \sum_{i=I(0, t_-, s_-)}^{I_{t-1}^{(k, t_-, s_-)}} \|x_{i+1} - x_i\|^2 + \sum_{i=I(k, t_-, s_-)}^{I_{t-1}^{(k, t_-, s_-)}} \|x_{i+1} - x_i\|^2.
\]

Using this, we have

\[
\sum_{t'=t-1}^{t-1} \sum_{i=I(t', s_-)}^{I(t', s_-)} \|u_i - \nabla f(x_i)\|^2 
\leq 12c^2 \left( \frac{KL^2}{b} + K^2 \zeta^2 + \frac{KL^2 T}{Pb} \right) 
\times \left( \frac{(I(K-1, t-1, s_-) - I(0, t-1, s_-) + 1) \land K}{K} I_{t-1}^{(k, t-1, s_-)} \sum_{i=I(0, t-1, s_-)}^{I_{t-1}^{(k, t-1, s_-)}} \|x_{i+1} - x_i\|^2 
\leq \frac{(I(K-1, t-1, s_-) - I(0, t-1, s_-) + 1) \land K}{K} I_{t-1}^{(k, t-1, s_-)} \sum_{i=I(0, t-1, s_-)}^{I_{t-1}^{(k, t-1, s_-)}} \|x_{i+1} - x_i\|^2 
\leq \frac{(I(K-1, t-1, s_-) - I(0, t-1, s_-) + 1) \land K}{K} I_{t-1}^{(k, t-1, s_-)} \sum_{i=I(0, t-1, s_-)}^{I_{t-1}^{(k, t-1, s_-)}} \|x_{i+1} - x_i\|^2 
\right) 
\times \left( \frac{2KTSd}{q} + \log \log \frac{4KTG}{\varepsilon} \right) 
+ (I(K-1, t-1, s_-) - I(0, t-1, s_-) + 1)r^2.
\]

Finally, we bound the last term:

\[
\sum_{i=I(0, t, s_-)}^{I(0, t, s_-)} \|u_i - \nabla f(x_i)\|^2 
\leq 12c^2 \left( \frac{KL^2}{b} + K^2 \zeta^2 + \frac{KL^2 T}{Pb} \right) 
\times \left( \frac{(I(k, t, s_-) - I(0, t, s_-) + 1) \land K}{K} I_{t}^{(k, t, s_-)} \sum_{i=I(0, t, s_-)}^{I_{t}^{(k, t, s_-)}} \|x_{i+1} - x_i\|^2 
\leq \frac{(I(k, t, s_-) - I(0, t, s_-) + 1) \land K}{K} I_{t}^{(k, t, s_-)} \sum_{i=I(0, t, s_-)}^{I_{t}^{(k, t, s_-)}} \|x_{i+1} - x_i\|^2 
\leq \frac{(I(k, t, s_-) - I(0, t, s_-) + 1) \land K}{K} I_{t}^{(k, t, s_-)} \sum_{i=I(0, t, s_-)}^{I_{t}^{(k, t, s_-)}} \|x_{i+1} - x_i\|^2 
\times \left( \frac{2KTSd}{q} + \log \log \frac{4KTG}{\varepsilon} \right) 
+ (I(k, t, s_-) - I(0, t, s_-) + 1)r^2.
\]

22
Summing the upper bounds of the three terms, we get

\[
\sum_{i=I(k, t, s_0)}^{I(k, t, s_0) - 1} \|v_i - \nabla f(x_i)\|^2 
\leq 48c^2 \left( \frac{KL^2}{b} + K^2 \zeta^2 + \frac{KL^2 T}{Pb} \right) 
\times \left( \sum_{i=I(k, t, s_0)}^{I(k, t, s_0) - 1} \|x_{i+1} - x_i\|^2 + \frac{(I(k, t, s_0) - I(k_0, t_0, s_0) - 1) \wedge K}{K} \sum_{i=I(0, t, s_0)}^{I(k_0, t_0, s_0) - 1} \|x_{i+1} - x_i\|^2 
+ \frac{(I(k, t, s_0) - I(k_0, t_0, s_0) - 1) \wedge K}{K} \sum_{i=I(0, t, s_0)}^{I(k_0, t_0, s_0) - 1} \|x_{i+1} - x_i\|^2 \right) 
\times \left( \log \frac{2KTSd}{q} + \log \log \frac{G}{\epsilon} \right) 
+ (I(k, t, s_0) - I(k_0, t_0, s_0) - 1) \rho^2.
\]

Setting \( k_0 \leftarrow k_0, t_0 \leftarrow t_0 \) and \( s_0 \leftarrow s_0 \) gives the desired bound.

**Case III.** \( s > s_0 \)

In this case, note that \( I(k, t, s) - I(k_0, t_0, s_0) \geq KT \) holds. Observe that

\[
\sum_{i=I(k_0, t_0, s_0)}^{I(k-1, T-1, s_0)} \|v_i - \nabla f(x_i)\|^2 
\leq \sum_{i=I(k_0, t_0, s_0)}^{I(k-1, T-1, s_0)} \|v_i - \nabla f(x_i)\|^2 
+ \sum_{s' = s_0 + 1}^{s_0} \sum_{i=I(0, 0, s')}^{I(k-1, T-1, s')} \|v_i - \nabla f(x_i)\|^2 
+ \sum_{i=I(0, 0, s)}^{I(k(t, s))} \|v_i - \nabla f(x_i)\|^2.
\]

Using the result of Case II, we bound the three terms.

The first term can be bounded as follows:

\[
\sum_{i=I(k_0, t_0, s_0)}^{I(k-1, T-1, s_0)} \|v_i - \nabla f(x_i)\|^2 
\leq 48c^2 \left( \frac{KL^2}{b} + K^2 \zeta^2 + \frac{KL^2 T}{Pb} \right) 
\times \left( \sum_{i=I(k_0, t_0, s_0)}^{I(k-1, T-1, s_0) - 1} \|x_{i+1} - x_i\|^2 + \frac{(I(k-1, T-1, s_0) - I(k_0, t_0, s_0) + 1) \wedge K}{K} \sum_{i=I(0, t_0, s_0)}^{I(k_0, t_0, s_0) - 1} \|x_{i+1} - x_i\|^2 
+ \frac{(I(k-1, T-1, s_0) - I(k_0, t_0, s_0) + 1) \wedge KT}{KT} \sum_{i=I(0, t_0, s_0)}^{I(k_0, t_0, s_0) - 1} \|x_{i+1} - x_i\|^2 \right) 
\times \left( \log \frac{2KTSd}{q} + \log \log \frac{G}{\epsilon} \right) 
+ (I(k-1, T-1, s_0) - I(k_0, t_0, s_0) + 1) \rho^2.
\]
Similarly, the second term can be bounded as

\[
\sum_{s' = s_0 + 1}^{s-1} I(K-1, T-1, s') \sum_{i = I(0,0, s')} \|v_i - \nabla f(x_i)\|^2
\]

\[
\leq 48c^2 \left( \frac{KL^2}{b} + K^2 \zeta^2 + \frac{KL^2 T}{Pb} \right) \left( \sum_{s' = s_0 + 1}^{s-1} I(K-1, T-1, s') \sum_{i = I(0,0, s')} \|x_{i+1} - x_i\|^2 \right) \left( \log \frac{2KTSd}{q} + \log \log \frac{4KTG}{\epsilon} \right)
\]

\[
+ (I(K-1, T-1, s-1) - I(k_0, t_0, s_0 + 1) + 1)r^2.
\]

We bound the last term as

\[
\sum_{i = I(0,0, s)}^{I(k,t,s)} \|v_i - \nabla f(x_i)\|^2
\]

\[
\leq 48c^2 \left( \frac{KL^2}{b} + K^2 \zeta^2 + \frac{KL^2 T}{Pb} \right) \left( \sum_{i = I(0,0, s)}^{I(k,t,s)-1} \|x_{i+1} - x_i\|^2 \right) \left( \log \frac{KTSd}{q} + \log \log \frac{4KTG}{\epsilon} \right)
\]

\[
+ (I(k, t, s) - I(0, 0, s) + 1)r^2.
\]

Summing up the three terms, we get

\[
\sum_{i = I(k_0, t_0, s_0)}^{I(k,t,s)} \|v_i - \nabla f(x_i)\|^2
\]

\[
\leq 48c^2 \left( \frac{KL^2}{b} + K^2 \zeta^2 + \frac{KL^2 T}{Pb} \right) \left( \sum_{i = I(k_0, t_0, s_0)}^{I(k,t,s)-1} \|x_{i+1} - x_i\|^2 + \frac{(I(k, t, s) - I(k_0, t_0, s_0) + 1) \wedge K}{K} \sum_{i = I(0,0, s_0)}^{I(k_0, t_0, s_0)-1} \|x_{i+1} - x_i\|^2 \right)
\]

\[
\times \left( \log \frac{2KTSd}{q} + \log \log \frac{4KTG}{\epsilon} \right)
\]

\[
+ (I(k, t, s) - I(k_0, t_0, s_0) + 1) \wedge KT \frac{I(0,0, s_0)-1}{I(0,0, s_0)} \sum_{i = I(0,0, s_0)}^{I(k_0, t_0, s_0)-1} \|x_{i+1} - x_i\|^2
\]

\[
\times \left( \log \frac{2KTSd}{q} + \log \log \frac{4KTG}{\epsilon} \right)
\]

\[
+ (I(k, t, s) - I(k_0, t_0, s_0) + 1)r^2.
\]
Combining the three cases, we obtain

\[
\begin{align*}
I(k,t,s) &\leq 48c^2 \left( \frac{KL^2}{b} + K^2 \zeta^2 + \frac{KTL^2}{Pb} \right) \\
&\times \left( \sum_{i=I(k_0,t_0,s_0)}^{I(k,t,s)-1} \|x_{i+1} - x_i\|^2 + \frac{I(k,t,s) - I(k_0,t_0,s_0) + 1)}{K} \sum_{i=I(0,t_0,s_0)}^{I(k_0,t_0,s_0)-1} \|x_{i+1} - x_i\|^2 \\
&+ \left( \frac{I(k,t,s) - I(k_0,t_0,s_0) + 1)}{KT} \sum_{i=I(0,t_0,s_0)}^{I(0,t_0,s_0)-1} \|x_{i+1} - x_i\|^2 \\
&\times \left( \log \frac{2KTSd}{q} + \log \log \frac{4KTG}{\varepsilon} \right) \right) \\
&\times \left( \frac{I(k,t,s) - I(k_0,t_0,s_0) - 1)}{K} \sum_{i=I(0,t_0,s_0)}^{I(k_0,t_0,s_0)-1} \|x_{i+1} - x_i\|^2 \\
&+ \left( \frac{I(k,t,s) - I(k_0,t_0,s_0) - 1)}{KT} \sum_{i=I(0,t_0,s_0)}^{I(0,t_0,s_0)-1} \|x_{i+1} - x_i\|^2 \\
&\times \left( \log \frac{2KTSd}{q} + \log \log \frac{4KTG}{\varepsilon} \right) \right) \\
&\times \left( \frac{I(k,t,s) - I(k_0,t_0,s_0) + 1)}{KT} \sum_{i=I(0,t_0,s_0)}^{I(0,t_0,s_0)-1} \|x_{i+1} - x_i\|^2 \\
&+ \eta(I(k,t,s) - I(k_0,t_0,s_0))r^2 \\
\right) \\
&\text{with probability at least } 1 - 3q.
\end{align*}
\]

We can choose \( \eta = \bar{O}(1/L \wedge \sqrt{b/K} / L \wedge 1/(K\zeta) \wedge \sqrt{Pb}/(\sqrt{KTL})) \) such that \( \eta \leq 1/(8L) \) and

\[
48c^2 \eta \left( \frac{KL^2}{b} + K^2 \zeta^2 + \frac{KTL^2}{Pb} \right) \left( \log \frac{2KTSd}{q} + \log \log \frac{4KTG}{\varepsilon} \right) \leq \frac{c\eta}{\eta}.
\]
for some constant $c_\eta \in (0, 1/4)$. Then, the above result can be simplified as

$$f(x_{I(k,t,s)}) \leq f(x_{I(k_0,t_0,s_0)}) - \frac{\eta}{2} \sum_{i=I(k_0,t_0,s_0)}^{I(k,t,s)-1} \|\nabla f(x_i)\|^2 - \frac{1}{8\eta} \sum_{i=I(k_0,t_0,s_0)}^{I(k,t,s)-1} \|x_{i+1} - x_i\|^2$$

$$+ \frac{c_\eta}{\eta} \left( \frac{(I(k,t,s) - I(k_0,t_0,s_0)) \wedge K}{K} \sum_{i=I(0,t_0,s_0)}^{I(k_0,t_0,s_0)-1} \|x_{i+1} - x_i\|^2 \right)$$

$$+ \frac{8\eta(I(k,t,s) - I(k_0,t_0,s_0))}{K} \left( f(x_{I(k_0,t_0,s_0)}) - f(x_{I(k,t,s)}) \right)$$

$$- \frac{1}{8\eta} \sum_{i=I(k_0,t_0,s_0)}^{I(k-1,t,s)} \|x_{i+1} - x_i\|^2$$

$$+ \frac{c_\eta}{\eta} \left( \frac{(I(k,t,s) - I(k_0,t_0,s_0)) \wedge K}{K} \sum_{i=I(0,t_0,s_0)}^{I(k_0,t_0,s_0)-1} \|x_{i+1} - x_i\|^2 \right)$$

$$+ \frac{8\eta(I(k,t,s) - I(k_0,t_0,s_0))}{K} \left( f(x_{I(k_0,t_0,s_0)}) - f(x_{I(k,t,s)}) \right)$$

$$+ \eta(I(k,t,s) - I(k_0,t_0,s_0))r^2 \right\}.$$  

with probability at least $1 - 3q$. □

Also, we bound $\|x_{I(k,t,s)} - x_{I(k_0,t_0,s_0)}\|^2$. Note that

$$\|x_{I(k,t,s)} - x_{I(k_0,t_0,s_0)}\|^2 \leq (I(k,t,s) - I(k_0,t_0,s_0)) \sum_{i=I(k_0,t_0,s_0)}^{I(k,t,s)-1} \|x_{i+1} - x_i\|^2$$

$$\leq 8\eta(I(k,t,s) - I(k_0,t_0,s_0)) \left( f(x_{I(k_0,t_0,s_0)}) - f(x_{I(k,t,s)}) \right)$$

$$- \frac{1}{8\eta} \sum_{i=I(k_0,t_0,s_0)}^{I(k-1,t,s)} \|x_{i+1} - x_i\|^2$$

$$+ \frac{c_\eta}{\eta} \left( \frac{(I(k,t,s) - I(k_0,t_0,s_0)) \wedge K}{K} \sum_{i=I(0,t_0,s_0)}^{I(k_0,t_0,s_0)-1} \|x_{i+1} - x_i\|^2 \right)$$

$$+ \frac{8\eta(I(k,t,s) - I(k_0,t_0,s_0))}{K} \left( f(x_{I(k_0,t_0,s_0)}) - f(x_{I(k,t,s)}) \right)$$

$$+ \eta(I(k,t,s) - I(k_0,t_0,s_0))r^2 \right\}.$$  

for every $k, k_0 \in [K - 1], t, t_0 \in [T - 1]$ and $s, s_0 \in [S - 1]$ ($I(k,t,s) \geq I(k_0,t_0,s_0)$) with probability at least $1 - 3q$.

By the way, we also derive (loose) almost sure bound as follows: From [1] and the fact that $\|x_{I(k,t,s)} - \nabla f(x_{I(k,t,s)})\|^2 \leq 3(4KG^2 + 4KG^2 + 4TG^2) \leq 36KTG^2$ almost surely, it holds that

$$f(x_{I(k,t,s)}) - f(x_{I(k_0,t_0,s_0)}) \leq 36\etaKT(I(k,t,s) - I(k_0,t_0,s_0))G^2 + \eta(I(k,t,s) - I(k_0,t_0,s_0))r^2$$

$$\leq 36\etaK^2T^2G^2 + \etaKTSr^2$$

$$\leq 36\etaK^2T^2S(G^2 + r^2)$$  

(5)

almost surely.
Proof of Corollary 4.2

Using Proposition 4.1 with \( I(k, t, s) = KT S \) and \( I(k_0, t_0, s_0) = 0 \), we have

\[
f(x_{KT S}) \leq f(x_0) - \frac{\eta}{2} \sum_{i=0}^{KT S-1} \|\nabla f(x_i)\|^2 - \frac{1}{8\eta} \sum_{i=0}^{KT S-1} \|x_{i+1} - x_i\|^2 + \eta KT S r^2.
\]

Then, \(-\|\nabla f(x_i)\|^2 \leq -(1/2)\|\nabla f(x_i)\|^2 + \|\nabla f(x_i) - f(x_i)\|^2 \leq -(1/2)\|\nabla f(x_i)\|^2 + \eta^2 L^2 r^2 \leq -(1/2)\|\nabla f(x_i)\|^2 + r^2\) gives

\[
f(x_{KT S}) \leq f(x_0) - \frac{\eta}{4} \sum_{i=0}^{KT S-1} \|\nabla f(x_i)\|^2 - \frac{1}{8\eta} \sum_{i=0}^{KT S-1} \|x_{i+1} - x_i\|^2 + 2\eta KT S r^2.
\]

Choosing \( r \leq 1/4 \) immediately leads the desired result. \(\square\)

B.4 Escaping Saddle Points

Given \( \{x_i\}_{i=0}^{KT S-1} \), we introduce the concept of coupling sequence \[10\]. Given \( x_i(k_0, t_0, s_0) \), let \( \{e_i\}_{i=1}^d \) be the normalized eigenvectors of \( \nabla f(x_i(k_0, t_0, s_0)) \) associated with the eigenvalues \( \lambda_1 < \cdots < \lambda_d \). We set \( e_{min} := e_1 \) and \( \lambda_{min} := \lambda_1 \). We assume that \( \lambda := -\lambda_{min} > \sqrt{\rho_e} \).

Then, for given \( i \geq I(k_0, t_0, s_0) \), we define coupling sequence \( \{x'_i\}_{i=0}^{KT S-1} \) as follows: (1) \( \langle \xi'_i, e_{min} \rangle = -\langle \xi_i, e_{min} \rangle \); (2) \( \langle \xi'_i, e_j \rangle = \langle \xi_i, e_j \rangle \) for \( j \in \{2, \ldots, d\} \); and (3) All other randomness is completely same as the one of \( \{x_i\}_{i=0}^{KT S-1} \). Let \( r_0 := \|\xi_i, e_{min}\| \). Note that \( \|\xi_i - \xi'_i, e_{min}\| = 2r_0 \) and thus \( \|\xi_i - \xi'_i\| = 2r_0 \). Also, observe that \( x_{i+1} = \eta(\xi_i - \xi'_i, e_{min})e_{min} \). We define \( i \) used in the definition of the coupling sequence as follows:

\[
\bar{i} := \begin{cases} 
I(k_0, t_0, s_0), & (1/(\eta \lambda) \leq \sqrt{\bar{K}}) \\
I(k'_0, t_0, s_0) - 1, & (\sqrt{\bar{K}} < 1/(\eta \lambda) \leq K) \\
I(0, t_0 + 1, s_0) - 1, & (K < 1/(\eta \lambda) \leq KT) \\
I(0, 0, s_0 + 1) - 1, & (KT < 1/(\eta \lambda))
\end{cases}
\]

Here, \( k'_0 \) is the minimum index \( k \) that satisfies \( k > k_0 \) and \( k \equiv 0 \) (mod \( \sqrt{\bar{K}} \)). We can easily check that \( \bar{i} - I(k_0, t_0, s_0) \leq 1/(\eta \lambda) \).

Note that

\[
\mathbb{P}\left( r_0 \geq \frac{q r}{2\sqrt{d}} \right) \geq 1 - q
\]

from the arguments in Section A.2 of [8].

To prove Proposition 4.3 first note that the following result:

**Proposition B.3.** Let \( k_0 \in [K] \cup \{0\} \), \( t_0 \in [T - 1] \cup \{0\} \) and \( s_0 \in [S - 1] \cup \{0\} \). Fix any \( J \in\{1, \ldots, I(0, 0, S) - I(k_0, t_0, s_0)\} \) and \( F > 0 \). Under the same conditions as Proposition 4.1 it holds that

\[
\min \left\{ f(x_{I(k_0, t_0, s_0) + J}) - f(x_{I(k_0, t_0, s_0)}), f(x'_{I(k_0, t_0, s_0) + J}) - f(x'_{I(k_0, t_0, s_0)}) \right\} \leq -F + \frac{2c_{e}}{\eta} \left( J \wedge K \right) \sum_{i=I(0, 0, s_0)}^{I(0, 0, s_0) - 1} \|x_{i+1} - x_i\|^2 + \frac{F \wedge KT}{K} \sum_{i=I(0, 0, s_0)}^{I(0, 0, s_0) - 1} \|x_{i+1} - x_i\|^2
\]

or \( \forall J \in [J] : \max \left\{ \|x_{I(k_0, t_0, s_0) + J} - x_{I(k_0, t_0, s_0)}\|^2, \|x'_{I(k_0, t_0, s_0) + J} - x'_{I(k_0, t_0, s_0)}\|^2 \right\} \leq 8\eta \left( F + 2\eta F r^2 \right)\)
with probability at least $1 - 6q$.

**Proof.** First note that $x_i = x'_i$ for $i \leq I(k_0, t_0, s_0)$. From the bounds of $\|x_{I(k_0, t_0, s_0) + J} - x'_{I(k_0, t_0, s_0) + J} - x''_{I(k_0, t_0, s_0) + J}\|^2$, we can see that

$$
\max \left\{ \|x_{I(k_0, t_0, s_0) + J} - x'_{I(k_0, t_0, s_0) + J} - x''_{I(k_0, t_0, s_0) + J}\|^2 \right\}
\leq 8\eta J \left( \max \left\{ f(x_{I(k_0, t_0, s_0)}) - f(x_{I(k_0, t_0, s_0) + J}) \right\} - \frac{1}{8\eta} \sum_{i = I(k_0, t_0, s_0)}^{I(k_0, t_0, s_0) + J - 1} \|x_{i+1} - x_i\|^2 \right)
$$

$$
f(x'_{I(k_0, t_0, s_0)}) - f(x''_{I(k_0, t_0, s_0) + J}) - \frac{1}{8\eta} \sum_{i = I(k_0, t_0, s_0)}^{I(k_0, t_0, s_0) + J - 1} \|x'_{i+1} - x'_i\|^2
$$

$$+ \frac{c_\eta}{\eta} \left( \frac{J \wedge K}{J} \sum_{i = I(0, t_0, s_0)}^{I(0, t_0, s_0) - 1} \|x_{i+1} - x_i\|^2 + \frac{J \wedge K T}{K} \sum_{i = I(0, t_0, s_0)}^{I(0, t_0, s_0) - 1} \|x_{i+1} - x_i\|^2 \right) + \eta J^2
$$

for every $J \in [\mathcal{J}]$ with probability at least $1 - 6q$.

We define $I(k_j, t_j, s_j) := I(k_0, t_0, s_0) + J$. Note that $s_J \geq s_0$. From $\{\}$,

$$f(x_{I(k_0, t_0, s_0)}) - f(x_{I(k_0, t_0, s_0) + J}) - \frac{1}{8\eta} \sum_{i = I(k_0, t_0, s_0)}^{I(k_0, t_0, s_0) + J - 1} \|x_{i+1} - x_i\|^2
$$

$$= f(x_{I(k_0, t_0, s_0)}) - f(x_{I(k_0, t_0, s_0) + J})
$$

$$+ f(x_{I(k_0, t_0, s_0) + J}) - f(x_{I(k_0, t_0, s_0) + J}) - \frac{1}{8\eta} \sum_{i = I(k_0, t_0, s_0)}^{I(k_0, t_0, s_0) + J - 1} \|x_{i+1} - x_i\|^2
$$

$$\leq f(x_{I(k_0, t_0, s_0)}) - f(x_{I(k_0, t_0, s_0) + J})
$$

$$- \frac{1}{8\eta} \sum_{i = I(k_0, t_0, s_0)}^{I(k_0, t_0, s_0) + J - 1} \|x_{i+1} - x_i\|^2
$$

$$+ \frac{c_\eta}{\eta} \left( \frac{J \wedge K}{K} \sum_{i = I(0, t_0, s_0)}^{I(0, t_0, s_0) - 1} \|x_{i+1} - x_i\|^2 + \frac{J \wedge K T}{K} \sum_{i = I(0, t_0, s_0)}^{I(0, t_0, s_0) - 1} \|x_{i+1} - x_i\|^2 \right) + \eta J^2
$$

$$\leq f(x_{I(k_0, t_0, s_0)}) - f(x_{I(k_0, t_0, s_0) + J})
$$

$$+ \frac{c_\eta}{\eta} \left( \frac{J \wedge K}{K} \sum_{i = I(0, t_0, s_0)}^{I(0, t_0, s_0) - 1} \|x_{i+1} - x_i\|^2 + \frac{J \wedge K T}{K} \sum_{i = I(0, t_0, s_0)}^{I(0, t_0, s_0) - 1} \|x_{i+1} - x_i\|^2 \right) + \eta J^2
$$

Here, for the last inequality, we used the fact that $I(0, t_J, s_J) \geq I(0, t_0, s_0)$. Also, we assumed $c_\eta \leq 1/8$.

Similarly, we can show that

$$f(x'_{I(k_0, t_0, s_0)}) - f(x''_{I(k_0, t_0, s_0) + J}) - \frac{1}{8\eta} \sum_{i = I(k_0, t_0, s_0)}^{I(k_0, t_0, s_0) + J - 1} \|x'_{i+1} - x'_i\|^2
$$

$$\leq f(x'_{I(k_0, t_0, s_0)}) - f(x''_{I(k_0, t_0, s_0) + J})
$$

$$+ \frac{c_\eta}{\eta} \left( \frac{J \wedge K}{K} \sum_{i = I(0, t_0, s_0)}^{I(0, t_0, s_0) - 1} \|x_{i+1} - x_i\|^2 + \frac{J \wedge K T}{K} \sum_{i = I(0, t_0, s_0)}^{I(0, t_0, s_0) - 1} \|x_{i+1} - x_i\|^2 \right) + \eta J^2.
Therefore, we get
\[
\max \left\{ \|x_I(k_0,t_0,s_0)+J - x_I(k_0,t_0,s_0)\|^2, \|x'_I(k_0,t_0,s_0)+J - x'_I(k_0,t_0,s_0)\|^2 \right\} \\
\leq 8\eta J \left\{ -\min \left\{ f(x_I(k_0,t_0,s_0)+J) - f(x_I(k_0,t_0,s_0)), f'(x_I(k_0,t_0,s_0)+J) - f(x'_I(k_0,t_0,s_0)) \right\} \\
+ \frac{2c_F}{\eta} \left( \mathcal{J} \wedge K \frac{I(k_0,t_0,s_0)-1}{K} \sum_{i=I(0,0,s_0)} \|x_{i+1} - x_i\|^2 + \mathcal{J} \wedge K \frac{I(0,t_0,s_0)-1}{KT} \sum_{i=I(0,0,s_0)} \|x_{i+1} - x_i\|^2 \right) + 2\eta \mathcal{J} r^2 \right\}
\]
for every \( J \in [\mathcal{J}] \). Now, suppose that
\[
\min \left\{ f(x_I(k_0,t_0,s_0)+J) - f(x_I(k_0,t_0,s_0)), f'(x_I(k_0,t_0,s_0)+J) - f(x'_I(k_0,t_0,s_0)) \right\} > -\mathcal{F} + \frac{2c_F}{\eta} \left( \mathcal{J} \wedge K \frac{I(k_0,t_0,s_0)-1}{K} \sum_{i=I(0,0,s_0)} \|x_{i+1} - x_i\|^2 + \mathcal{J} \wedge K \frac{I(0,t_0,s_0)-1}{KT} \sum_{i=I(0,0,s_0)} \|x_{i+1} - x_i\|^2 \right). \tag{7}\]
Then, using (7), we obtain
\[
\max \left\{ \|x_I(k_0,t_0,s_0)+J - x_I(k_0,t_0,s_0)\|^2, \|x'_I(k_0,t_0,s_0)+J - x'_I(k_0,t_0,s_0)\|^2 \right\} \\
\leq 8\eta \mathcal{J} (\mathcal{F} + 2\eta \mathcal{J} r^2).
\]
This finishes the proof. \( \square \)

We fix \( k_0 \in [K-1], t_0 \in [T-1], s_0 \in [S-1] \) and \( J_I(k_0,t_0,s_0) \in \mathbb{N} \). Let \( \mathcal{F}_{I(k_0,t_0,s_0)} := c_F \eta J_I(k_0,t_0,s_0)r^2 \). From this definition, (4) immediately implies that
\[
f(x_I(k_0,t_0,s_0)+J) - f(x_I(k_0,t_0,s_0)) \\
\leq \frac{c_F}{\eta} \left( \mathcal{J} \wedge K \frac{I(k_0,t_0,s_0)-1}{K} \sum_{i=I(0,0,s_0)} \|x_{i+1} - x_i\|^2 + \mathcal{J} \wedge K \frac{I(0,t_0,s_0)-1}{KT} \sum_{i=I(0,0,s_0)} \|x_{i+1} - x_i\|^2 \right) + \eta \mathcal{J} r^2.
\]
for every \( J \in [J_I(k_0,t_0,s_0)] \) with probability at least \( 1 - 3q \). Here, for simplifying the notations, we set \( \mathcal{F} := \mathcal{F}_{I(k_0,t_0,s_0)} \) and \( \mathcal{J} := J_I(k_0,t_0,s_0) \).

We want to show the following proposition:

**Proposition B.4.** Under the same conditions as Proposition [4,3] it holds that
\[
\max \left\{ \|x_I(k_0,t_0,s_0)+J - x_I(k_0,t_0,s_0)\|^2, \|x'_I(k_0,t_0,s_0)+J - x'_I(k_0,t_0,s_0)\|^2 \right\} > 8(c_F + 2)\eta^2 J^2 r^2
\]
for some \( J \in [\mathcal{J}] \) with probability at least \( 1 - 3q \).

**Proof.** We consider the event \( H \) that is an intersection of (6), (14) and (15) (derived later), which has probability at least \( 1 - 3q \). From now, the arguments are conditioned on \( H \). Observe that \( 8\eta \mathcal{J} (\mathcal{F} + 2\eta \mathcal{J} r^2) = 8(c_F + 2)\eta^2 J^2 r^2 \).

Suppose that
\[
\max \left\{ \|x_I(k_0,t_0,s_0)+J - x_I(k_0,t_0,s_0)\|^2, \|x'_I(k_0,t_0,s_0)+J - x'_I(k_0,t_0,s_0)\|^2 \right\} \leq 8(c_F + 2)\eta^2 J^2 r^2,
\]
which implies
\[
\max \left\{ \|x_I(k_0,t_0,s_0)+J - x_I(k_0,t_0,s_0)\|, \|x'_I(k_0,t_0,s_0)+J - x'_I(k_0,t_0,s_0)\| \right\} \leq 2 \sqrt{2(c_F + 2)\eta \mathcal{J} r}.
\]

29
We will derive a contradiction. Now, we consider the quantity $\|x_i - x_i'\|^2$ for $i > \bar{I}$. $w_i$ denotes $x_i - x_i'$. Since $\xi_i = \xi_i'$ for $i \neq \bar{I}$, for $I \geq \bar{I}$, we have that 

$$w_{i+1} = x_{i+1} - x'_{i+1}$$

$$= w_I - \eta(v_I - v'_I) - \eta(\xi_I - \xi'_I)$$

$$= w_I - \eta(\nabla f(x_I) - \nabla f(x'_I) + v_I - \nabla f(x_I) - v'_I + \nabla f(x'_I))$$

$$= w_I - \eta((H + \Delta I)w_I + v_I - \nabla f(x_I) - v'_I + \nabla f(x'_I))$$

$$= (1 - \eta H)w_I - \eta(\Delta I w_I + y_I)$$

$$= \eta(1 - \eta H)^{I-I} \xi_I - \eta \sum_{i=\bar{I}}^{I} (1 - \eta H)^{I-i} (\Delta_i w_i + y_i),$$

where $\mathcal{H} := \nabla^2 f(\bar{x}_{I(k_0,t_0,0)}), \Delta_i := \int_0^1 (\nabla^2 f(\theta x_i + (1 - \theta) x'_i) - \mathcal{H})d\theta, y_i := v_i - \nabla f(x_i) - v'_i + \nabla f(x'_i)$ and $\hat{\xi}_I = \xi_I - \xi'_I$. Let $\lambda := -\lambda_{\min}(\nabla^2 f(\bar{x}_{I(k_0,t_0,0)}) > \sqrt{\rho}$. For the last inequality, we used $\bar{x}_{\bar{I}} = \bar{x}_I$.

First we give an upper bound of the term $\|\eta(1 - \eta H)^{I-I} \xi_I\|$. Since $\hat{\xi}_I = \xi_I - \xi'_I = 2\langle \xi_I, e_{\text{min}} \rangle e_{\text{min}}$, we have 

$$\eta(1 - \lambda H)^{I-I} \hat{\xi}_I = 2(\xi_I, e_{\text{min}}) e_{\text{min}}.$$ 

Since $r_0 = 2\|\langle \xi_I, e_{\text{min}} \rangle\|$, we have 

$$\left\|\eta(1 - \lambda H)^{I-I} \hat{\xi}_I \right\| = \eta(1 + \lambda)^{I-I} r_0 =: U_\xi(I). \tag{9}$$

From now, we will show that the following claims hold for $I \in \{0, \ldots, I(k_0, t_0, 0) + J\}$ with probability at least $1 - q$ using mathematical induction: 

$$\|w_I\| \leq c_{\text{upper}}^{(w)} \eta(1 + \lambda)^{I-I} r_0 =: U_w(I)$$

for $c_{\text{upper}}^{(w)} = \tilde{\Theta}(1) > 0$, and 

$$\|y_I\| \leq c_{\text{upper}}^{(y)} \eta^2 \lambda \left( L + \frac{\sqrt{K L}}{\sqrt{b}} + K \zeta + \frac{\sqrt{K T L}}{\sqrt{Pb}} \right) (1 + \lambda)^{I-I} r_0 =: U_y(I)$$

for some $c_{\text{upper}}^{(y)} = \tilde{\Theta}(1) > 0$. Observe that $U_\xi, U_w$ and $U_y$ are monotonically increasing with respect to $I$ for $I \geq \bar{I}$. First we check the case $I \in \{0, \ldots, \bar{I}\}$. In this case, the both claims trivially holds from the definition of $\{x_I'\}_{i=0}^{KTS-1}$ because $w_i = y_i = 0$ for $i \leq \bar{I}$. Suppose that the two claims hold for the cases $\{0, \ldots, \bar{I}\}$ with $I \geq \bar{I}$. We want to show that the two claims also hold for the case $I + 1 > \bar{I}$.

$$\|w_{I+1}\| \leq \eta \sum_{i=I}^{I} (1 + \lambda)^{I-i} \|\Delta_i w_i\| + \eta \sum_{i=I}^{I} (1 + \lambda)^{I-i} \|y_i\| + U_\xi(I + 1).$$

Here we used inequality $\tag{9}$. Observe that 

$$\|\Delta_i w_i\| \leq \|\Delta_i\| \|w_i\| \leq \|\Delta_i\| U_w(i) \leq \|\Delta_i\| U_w(I + 1)$$
and
\[ \| \Delta_i \| \leq \rho \int_0^1 \| \theta x_i + (1 - \theta)x'_i - \bar{x}_i(k_1, t_0, s_0) \| d\theta \]
\[ \leq p \max \{ \| x_i - \bar{x}_i(k_1, t_0, s_0) \|, \| x'_i - \bar{x}'_i(k_1, t_0, s_0) \| \} \]
\[ \leq \rho U_\Delta. \]

Hence, we get
\[ \eta \sum_{i=I}^{I} (1 + \eta \lambda)^{I-i} \| \Delta_i w_i \| \leq \| y_i \| \]
\[ \leq (1 + \eta \lambda)^{I-i} \| y_i \| \]
\[ \leq c_{\text{upper}} \eta \lambda \cdot \eta \left( L + \sqrt{KL} \sqrt{b} + K\zeta + \sqrt{KTL} \sqrt{Pb} \right) (1 + \eta \lambda)^{I-I_0} \]
\[ \leq \left( \frac{c_{\text{upper}} \eta \lambda \cdot \eta \left( L + \sqrt{KL} \sqrt{b} + K\zeta + \sqrt{KTL} \sqrt{Pb} \right)}{c_{\text{upper}}} \right) U_w(I). \]
\[ (11) \]

These results imply
\[ \| w_{I+1} \| \leq \eta_pJU_\Delta U_w(I + 1) + \left( \frac{c_{\text{upper}} \eta \lambda \cdot \eta \left( L + \sqrt{KL} \sqrt{b} + K\zeta + \sqrt{KTL} \sqrt{Pb} \right)}{c_{\text{upper}}} \right) U_w(I + 1) \]
\[ \leq \left( \eta_pJU_\Delta + \frac{c_{\text{upper}} \eta \lambda \cdot \eta \left( L + \sqrt{KL} \sqrt{b} + K\zeta + \sqrt{KTL} \sqrt{Pb} \right)}{c_{\text{upper}}} + \frac{1}{c_{\text{upper}}} \right) U_w(I + 1). \]

Here, we again used the monotonicity of \( U_w(I) \) with respect to \( i \). Now, we define \( \tilde{J} := \tilde{J}(k_1, t_0, s_0) \) for some \( c_{\tilde{J}} := \Theta(1) \geq 2 \), which does not depend on index \( I(k_1, t_0, s_0) \) and will be determined later. Also, we set \( c_{\text{upper}} \geq 3 \) and \( c_{\text{upper}} \). These definitions with appropriate \( \eta \leq 1/(c_{\tilde{J}}(L + \sqrt{KL} \sqrt{b} + K\zeta + \sqrt{KTL} \sqrt{Pb})) \times 1/(6c_{\text{upper}}) = \Theta(1/L \wedge \sqrt{b/K} + 1/(K\zeta) \wedge \sqrt{Pb} / (\sqrt{KTL}) \text{ and } c_r \leq 1/(24\sqrt{c_{\tilde{J}}} + 2c_{\text{upper}}^2) \) give
\[ \eta_pJU_\Delta \leq 4c_r \sqrt{c_{\tilde{J}}} + 4 \times \eta^2 J^2 \rho \leq \frac{1}{6c_{\text{upper}}} \leq \frac{1}{18} \]
\[ (12) \]
and
\[ \frac{c_{\text{upper}} \eta \lambda \cdot \eta \left( L + \sqrt{KL} \sqrt{b} + K\zeta + \sqrt{KTL} \sqrt{Pb} \right)}{c_{\text{upper}}} \leq \frac{1}{6c_{\text{upper}}} \leq \frac{1}{18}. \]
\[ (13) \]

Hence, we obtain
\[ \| w_{I+1} \| \leq \frac{4}{9} U_w(I + 1) \leq U_w(I + 1). \]

Next, we consider the quantity \( \| y_{I+1} \| \). Let \( k, t, s \) be \( I + 1 = I(k, t, s) \). We define
\[ \alpha_{I(k, t, s)} := g_{I(k, t, s)} - g_{I(k, t, s)}^{ref} + \nabla f_{p_1, s}(x_{I(k-1, t, s)}) - \nabla f_{p_1, s}(x_{I(k, t, s)}), \]
\[ \beta_{I(k, t, s)} := \nabla f_{p_1, s}(x_{I(k, t, s)}) - \nabla f_{p_1, s}(x_{I(k-1, t, s)}) + \nabla f(x_{I(k-1, t, s)}) - \nabla f(x_{I(k, t, s)}), \]
\[ \gamma_{I(0, t, s)} := \frac{1}{p} \nabla f_{p, s}(x_{I(0, t, s)}) - g_{I(0, t, s)} + \nabla f(x_{I(0, t-1, s)}) - \nabla f(x_{I(0, t, s)}). \]
Similarly, we define

\[
\begin{align*}
\alpha'_{I(k,t,s)} & := g'_{I(k,t,s)} - (g'_{I(k,t,s)})' + \nabla f_{I(k,t,s)} (x'_{I(k-1,t,s)}) - \nabla f_{I(k,t,s)} (x'_{I(k,t,s)}), \\
\beta'_{I(k,t,s)} & := \nabla f_{I(k,t,s)} (x'_{I(k,t,s)}) - \nabla f_{I(k,t,s)} (x'_{I(k-1,t,s)}) + \nabla f (x'_{I(k-1,t,s)}) - \nabla f (x'_{I(k,t,s)}), \\
\gamma'_{I(0,t,s)} & := \frac{1}{p} \sum_{p=1}^{P} (g_{I(0,t,s)}^{p})' - (g_{I(0,t,s)}^{p}) + \nabla f (x'_{I(0,t-1,s)}) - \nabla f (x'_{I(0,t,s)}),
\end{align*}
\]

that are associated with sequence \(\{x'_i\}_{i=I(k_0,t_0,s_0)}^{\infty}\). Let \(\hat{\alpha}_{I(k,t,s)} = \alpha_{I(k,t,s)} - \alpha'_{I(k,t,s)}, \hat{\beta}_{I(k,t,s)} = \beta_{I(k,t,s)} - \beta'_{I(k,t,s)}\) and \(\hat{\gamma}_{I(k,t,s)} = \gamma_{I(k,t,s)} - \gamma'_{I(k,t,s)}\). Then we further define

\[
\begin{align*}
\hat{A}_{I(k,t,s)} & := \sum_{k=0}^{k-1} \hat{\alpha}_{I(k+1,t,s)}, \\
\hat{B}_{I(k,t,s)} & := \sum_{k=0}^{k-1} \hat{\beta}_{I(k+1,t,s)}, \\
\hat{C}_{I(0,t,s)} & := \sum_{\tau=0}^{\tau-1} \hat{\gamma}_{I(0,\tau+1,s)}
\end{align*}
\]

These definitions give

\[
y_{I+1} = v_{I+1} - \nabla f (x_{I+1}) - v'_{I+1} + \nabla f (x'_{I+1})
= \hat{A}_{I(k,t,s)} + \hat{B}_{I(k,t,s)} + \hat{C}_{I(0,t,s)}
+ v_{I(0,0,s)} - \nabla f (x_{I(0,0,s)}) - v'_{I(0,0,s)} + \nabla f (x'_{I(0,0,s)}),
\]

This implies

\[
\|y_{I+1}\| = \|v_{I+1} - \nabla f (x_{I+1}) - v'_{I+1} + \nabla f (x'_{I+1})\|
\leq \|\hat{A}_{I(k,t,s)}\| + \|\hat{B}_{I(k,t,s)}\| + \|\hat{C}_{I(0,t,s)}\|.
\]

Here, we used the fact that \(v_{I(0,0,s)} - \nabla f (x_{I(0,0,s)}) - v'_{I(0,0,s)} + \nabla f (x'_{I(0,0,s)}) = 0\).

**Bounding \(\|\hat{A}_{I(k,t,s)}\|\)**

Observe that \(\hat{\alpha}_{I(\kappa, t, s)}\) satisfies

\[
\mathbb{E}[\hat{\alpha}_{I(\kappa, t, s)} | F_{I(\kappa-1,t,s)}] = 0.
\]

Let

\[
\hat{u}^{(t)}_{I(\kappa, t, s)}(z_{I(\kappa, t, s)}) := \nabla \ell (x_{I(\kappa, t, s)}, z_{I(\kappa, t, s)}) - \nabla \ell (x'_{I(\kappa-1,t,s)}, z_{I(\kappa, t, s)}) - \nabla \ell (x'_{I(\kappa-1,t,s)}, z_{I(\kappa, t, s)})
+ (\nabla f_{I(\kappa-1,t,s)} (x'_{I(\kappa-1,t,s)}) - \nabla f_{I(\kappa-1,t,s)} (x'_{I(\kappa-1,t,s)})) - (\nabla f_{I(\kappa,t,s)} (x'_{I(\kappa,t,s)}) - \nabla f_{I(\kappa,t,s)} (x'_{I(\kappa,t,s)})).
\]
Note that $\mathbb{E}[\tilde{u}_{I(k,t,s)}^{(\alpha)} | \mathcal{F}_{I(k,t,s)-1}] = 0$ and $\hat{\alpha}_{I(k,t,s)} = (1/b) \sum_{l=1}^{b'} \tilde{u}_{I(k,t,s)}^{(\alpha)}$. Observe that
\[
\|\tilde{u}_{I(k,t,s)}^{(\alpha)}\| = \|\nabla \ell(x_{I(1,t,s)}^*, z_{I(1,t,s)}) - \nabla \ell(x_{I(1,t-1,s)}^*, z_{I(1,t-1,s)}) - \nabla \ell(x_{I(1-1,t,s)}^*, z_{I(1-1,t,s)}) + (\nabla f_{P_{I,s}}(x_{I(t,s)-1}) - \nabla f_{P_{I,s}}(x_{I(t,s)})) - (\nabla f_{P_{I,s}}(x_{I(t,s)-1}) - \nabla f_{P_{I,s}}(x_{I(t,s)}))\|
\]
\[
= \int_0^1 \nabla^2 \ell(\theta x_{I(t,s)}^*, z_{I(1,t,s)}) d\theta (x_{I(t,s)} - x_{I(t,s)}^*)
\]
\[
- \int_0^1 \nabla^2 \ell(\theta x_{I(t-1,s)}^*, z_{I(1,t,s)}) d\theta (x_{I(t,s)} - x_{I(t,s)}^*)
\]
\[
+ \int_0^1 \nabla^2 f_{P_{I,s}}(\theta x_{I(t,s)}^*) (1-\theta) x_{I(t,s)}^* d\theta (x_{I(t,s)} - x_{I(t,s)}^*)
\]
\[
- \int_0^1 \nabla^2 f_{P_{I,s}}(\theta x_{I(t-1,s)}^*) (1-\theta) x_{I(t-1,s)}^* d\theta (x_{I(t,s)} - x_{I(t,s)}^*)
\]
\[
= \|H_{z_{I(1,t,s)}}, w_{I(t,s)} - H_{z_{I(1,t-1,s)}}, w_{I(t,s)}\|\|w_{I(t,s)}\| + \|H_{P_{I,s}}, w_{I(t,s)} - H_{P_{I,s}}, w_{I(t,s)}\|\|w_{I(t,s)}\| + 2 \max\{\|x_{I(t,s)} - x_{I(k,t,s)}^*\|, \|x_{I(t,s)} - x_{I(k,t,s)}^*\|, \|x_{I(t,s)} - x_{I(k,t,s)}^*\|\}\|w_{I(t,s)}\| + \|w_{I(t,s)}\| + \|w_{I(t,s)}\|
\]
\[
\leq 2L\|w_{I(t,s)} - w_{I(t-1,s)}\| + 4\rho U^2 U_{w}(I+1).
\]

Here, $\mathcal{H}_{z_{I(1,t,s)}} := \nabla^2 \ell(x_{I(k,t,s),0})$, $\mathcal{H}_{P_{I,s}} := \nabla^2 f_{P_{I,s}}(x_{I(k,t,s),0})$, $\Delta_{z_{I(1,t,s)}} := \int_0^1 (\nabla^2 \ell(\theta x_{I(t,s)}, z_{I(1,t,s)}) - \mathcal{H}_{z_{I(1,t,s)}}) d\theta$, and $\Delta_{P_{I,s}, I(k,t,s)} := \int_0^1 (\nabla^2 f_{P_{I,s}}(\theta x_{I(t,s)}) + (1-\theta) x_{I(t,s)}^*) - \mathcal{H}_{P_{I,s}}) d\theta$.

We define $\mathcal{F}_{I(k,t,s)}^{(\alpha)} := 2L\|w_{I(t,s)} - w_{I(t-1,s)}\| + 4\rho U^2 U_{w}(I+1)$.

Here, for the last inequality, we used the inductive assumption on $\|w_{I(t,s)}\|$ for $I(k,t,s) \leq I(k-1,t,s)$ and the proven bound for $\|w_{I(t,s)}\|$. Also, we used the simple fact that $(1 + \eta \lambda)^{I(k,t,s)-1} \leq (1 + \eta \lambda)^{I+1-I(k,t,s)}$ and $H_{P_{I,s}}$ was bounded. Hence, we have
\[
\mathbb{P}(\|\tilde{u}_{I(k,t,s)}^{(\alpha)}\| \geq s | \mathcal{F}_{I(1,t,s)}) \leq 2e^{-\frac{s^2}{2 \mathcal{F}_{I(1,t,s)}^{(\alpha)}}}
\]

for every $s \in \mathbb{R}$ and $\kappa \in [k]$. Also note that $\{\tilde{u}_{I(k,t,s)}^{(\alpha)}\}_{\kappa=0}^{b}$ is i.i.d. sequence conditioned on $\mathcal{F}_{I(k-1,t,s)}$. Also note that $\|\hat{\alpha}_{I(k,t,s)}\| \leq 8G$ almost surely from Assumption 5. From these results, we can use Lemma 2 with $A = 8kG$ and $a = \varepsilon^2$ (c is some positive number and will be defined later) and get
\[
\|\hat{A}_{I(k,t,s)}\| \leq c \left( \left( \sum_{\kappa=0}^{k-1} \frac{1}{b_{\kappa+1}} \left( \mathcal{F}_{I(k-1,t,s)}^{(\alpha)} \right)^2 \right) + \varepsilon^2 \right) \left( \log \frac{2KT \rho I}{q} + \log \log \frac{8K G}{\varepsilon^2} \right)
\]

for every $k \in [K] \cup \{0\}$, $t \in [T-1] \cup \{0\}$ and $s \in [S] \cup \{0\}$ with probability at least $1 - q$ for some constant $c > 0$. Note that this event always holds under $H$.  

33
Bounding \( \|\hat{B}_{I(k,t,s)}\| \)

Observe that

\[
\hat{B}_{I(k,t,s)} = \nabla f_{p_{k,s}}(x_{I(k,t,s)}) - \nabla f_{p_{k,s}}(x_{I(0,t,s)}) + \nabla f(x_{I(0,t,s)}) - \nabla f(x_{I(k,t,s)})
+ \nabla f_{p_{k,s}}(x'_{I(k,t,s)}) - \nabla f_{p_{k,s}}(x'_{I(0,t,s)}) + \nabla f(x'_{I(0,t,s)}) - \nabla f(x'_{I(k,t,s)})
\]

\[
= \int_0^1 \nabla^2 f_{p_{k,s}}(\theta x_{I(k,t,s)} + (1 - \theta)x'_{I(k,t,s)}) d\theta(x_{I(k,t,s)} - x'_{I(k,t,s)})
- \int_0^1 \nabla^2 f_{p_{k,s}}(\theta x_{I(0,t,s)} + (1 - \theta)x'_{I(0,t,s)}) d\theta(x_{I(0,t,s)} - x'_{I(0,t,s)})
+ \int_0^1 \nabla^2 f(\theta x_{I(k,t,s)} + (1 - \theta)x'_{I(k,t,s)}) d\theta(x_{I(k,t,s)} - x'_{I(k,t,s)})
- \int_0^1 \nabla^2 f(\theta x_{I(0,t,s)} + (1 - \theta)x'_{I(0,t,s)}) d\theta(x_{I(0,t,s)} - x'_{I(0,t,s)})
\]

\[
= (\mathcal{H}_{p_{k,s}} + \Delta_{p_{k,s},I(k,t,s)}) w_{I(k,t,s)} - (\mathcal{H}_{p_{k,s}} + \Delta_{p_{k,s},I(0,t,s)}) w_{I(0,t,s)}
+ (\mathcal{H} + \Delta_{I(0,t,s)}) w_{I(0,t,s)} - (\mathcal{H} + \Delta_{I(0,t,s)}) w_{I(0,t,s)}
= (\mathcal{H}_{p_{k,s}} - \mathcal{H}) (w_{I(k,t,s)} - w_{I(0,t,s)})
+ (\Delta_{I(k,t,s),p_{k,s}} - \Delta_{I(k,t,s)}) w_{I(k,t,s)} - (\Delta_{I(0,t,s),p_{k,s}} - \Delta_{I(0,t,s)}) w_{I(0,t,s)}
\]

This implies that

\[
\|\hat{B}_{I(k,t,s)}\| \leq \zeta \|w_{I(k,t,s)} - w_{I(0,t,s)}\| + 4\rho U \Delta U w(I + 1)
\leq \zeta \sum_{k=0}^{k-1} \|w_{I(k+1,t,s)} - w_{I(k,t,s)}\| + 4\rho U \Delta U w(I + 1).
\]

Bounding \( \|\hat{C}_{I(0,t,s)}\| \)

The argument is similar to the case of \( \|\hat{A}_{I(k,t,s)}\| \). From Lemma [B.2], the third term \( \|\hat{C}_{I(0,t,s)}\| \) can be bounded as

\[
\|\hat{C}_{I(0,t,s)}\| \leq \frac{c}{\sqrt{PKt}} \left( \sum_{\tau=0}^{t-1} \left( \sigma_{I(0,\tau+1,s)}^{(\tau)} \right)^2 \right)^{\frac{1}{2}} \left( \log \frac{2KTSd}{q} + \log \log \frac{8TG}{\varepsilon} \right) (15)
\]

for every \( t \in [T - 1] \cup \{0\} \) and \( s \in [S - 1] \cup \{0\} \) with probability at least \( 1 - q \), where

\[
\sigma_{I(0,\tau,s)}^{(\tau)} := 2L \|w_{I(0,\tau,s)} - w_{I(0,\tau-1,s)}\| + 4\rho U \Delta U w(I + 1).
\]

Here, we used the facts that \( (g_{I(0,\tau,s)}^{(p)}) - g_{I(0,\tau-1,s)}^{(p)} + \nabla f_p(x_{I(0,\tau-1,s)}) - \nabla f_p(x_{I(0,s)}) \) has mean zero and each of them is constructed from \( K \) i.i.d. data samples, and \( (g_{I(0,\tau,s)}^{(p)}) - (g_{I(0,\tau,s)}^{(p)})' + \nabla f_p(x_{I(0,\tau-1,s)}) - \nabla f_p(x_{I(0,s)}) \) possesses the same property.
Hence, we have
\[
\begin{align*}
\|y_{I+1}\| &= |v_{I+1} - \nabla f(x_{I+1}) - v_{I+1} + \nabla f(x'_{I+1})| \\
&\leq \left\| \tilde{A}_{I(t,s)} \right\| + \left\| \tilde{B}_{I(t,s)} \right\| + \left\| \tilde{C}_{I(0,t,s)} \right\| + \sum_{k=0}^{k-1} \left( 8L^2 \sum_{\kappa=0}^{k-1} \frac{1}{b_{k+1}} \|w_{I(k+1,t,s)} - w_{I(k,t,s)}\|^2 + 32K \rho^2 U_{\Delta}^2 U_w(I + 1)^2 + \tilde{e}\right)
\end{align*}
\]

Next, suppose that \(k+1, \tau, s\). Suppose that \(k+1, \tau, s\) and \(k', \tau, s\). Suppose that \(k+1, \tau, s\) and \(k+1, \tau, s\) and \(k+1, \tau, s\) and \(k+1, \tau, s\) and \(k+1, \tau, s\) and \(k+1, \tau, s\).

For the former case, note that \(\|w_{i,k+1} - w_i\| = \|w_{i,k+1}\| = \eta r_0\). Also note that \(\|w_{I(k+1,t,s)} - w_{I(k,t,s)}\| = 0\) for \(I(k+1, t, s) < I + 1\).

**Case I.** \(1/(\eta \lambda) \leq \sqrt{K}\). 

In this case, \(I = I(k_0, t_0, s_0)\). Suppose that \(s = s_0\) and \(t = t_0\). Then, since \(1/(\eta \lambda) \leq \sqrt{K}\), it holds that
\[
\sum_{\kappa=0}^{k-1} \frac{1}{b_{k+1}} \|w_{I(k+1,t,s)} - w_{I(k,t,s)}\|^2 \leq \frac{1}{b} \sum_{i \in \{I(0,t,s),...,I(k-1,t,s)\} \setminus \{\tilde{I}\}} \|w_{i+1} - w_i\|^2 + \frac{\eta^2 \lambda^2}{b} r^2
\]
\[
\leq \frac{1}{b} \sum_{i \in \{I(0,t,s),...,I(k-1,t,s)\} \setminus \{\tilde{I}\}} \|w_{i+1} - w_i\|^2 + \frac{\eta^4 \lambda^2 K r^2}{b}
\]

and
\[
\sum_{\kappa=0}^{k-1} \|w_{I(k+1,t,s)} - w_{I(k,t,s)}\| \leq \sum_{i \in \{I(0,t,s),...,I(k-1,t,s)\} \setminus \{\tilde{I}\}} \|w_{i+1} - w_i\| + \eta r_0
\]
\[
\leq \sum_{i \in \{I(0,t,s),...,I(k-1,t,s)\} \setminus \{\tilde{I}\}} \|w_{i+1} - w_i\| + \eta^2 \lambda K r_0.
\]

Also, \(\sum_{t=0}^{t-1} \|w_{I(0,t+1,s)} - w_{I(0,t,s)}\|^2 = 0\).

Next, suppose that \(s = s_0\) and \(t > t_0\). Since \(I(0, t, s) > I(k_0, t_0, s_0)\), \(\|w_{I(k_0+1,t_0,s_0)} - w_{I(k_0,t_0,s_0)}\|\) does not appear in the two terms
\[
\sum_{\kappa=0}^{k-1} \frac{1}{b_{k+1}} \|w_{I(k+1,t,s)} - w_{I(k,t,s)}\|^2 \leq \frac{1}{b} \sum_{\kappa=0}^{k-1} \|w_{I(k+1,t,s)} - w_{I(k,t,s)}\|^2
\]

and
\[
\sum_{\kappa=0}^{k-1} \|w_{I(k+1,t,s)} - w_{I(k,t,s)}\|.
\]
Also, since $I(k_0, t_0, s_0) > I(0, 0, s)$,
\[
\sum_{\tau=0}^{t-1} \|w_I(0,\tau+1,s) - w_I(0,\tau, s)\|^2 = \sum_{\tau=0,\ldots,t-1} \|w_I(0,\tau+1,s) - w_I(0,\tau, s)\|^2 + \|w_I(0,t_0, s_0) - w_I(0, t_0, s)\|^2 \leq K \sum_{\eta \in \{0,\ldots,t-1\}\setminus\{I(0,t_0,s_0)\}} \|w_{\eta+1} - w_{\eta}\|^2 + 2K \sum_{\eta \in \{0,\ldots,t-1\}\setminus\{I(0,t_0,s_0)\}} \|w_{\eta+1} - w_{\eta}\|^2 + 2\eta^2 r_0^2 \]
\[
\leq 2K \sum_{\eta \in \{0,\ldots,t-1\}\setminus\{I(0,t_0,s_0)\}} \|w_{\eta+1} - w_{\eta}\|^2 + 2\eta^2 r_0^2 \]
\[
= 2K \sum_{\eta \in \{0,\ldots,t-1\}\setminus\{I(0,t_0,s_0)\}} \|w_{\eta+1} - w_{\eta}\|^2 + 2\eta^2 r_0^2 \]

Finally, when $s > s_0$, $\|w_{\eta+1} - w_{\eta}\|$ never appears in the bound of $\|y_I\|$.  

**Case II.** $\sqrt{K} < 1/(\eta \lambda) \leq K$.

In this case, $I = I(k_0', t_0, s_0) - 1$, where $k_0'$ is the minimum number that satisfies $k_0' > k_0$ and $k_0' \equiv 0 \pmod{\lceil \sqrt{K} \rceil}$. Note that $b_{k_0'} = \lfloor \sqrt{K} \rfloor b$.

Suppose that $s = s_0$ and $t = t_0$. Then, since $1/(\eta \lambda) \leq K$, it holds that
\[
\sum_{\kappa=0}^{k-1} \frac{1}{b_{k+1}} \|w_{I(\kappa+1,t,s)} - w_{I(\kappa,t,s)}\|^2 \leq \frac{1}{b} \sum_{\eta \in \{0,\ldots,t-1\}\setminus\{I(0,t,s)\}} \|w_{\eta+1} - w_{\eta}\|^2 + \frac{\eta^2 r_0^2}{\sqrt{K} b}
\]
and
\[
\sum_{\kappa=0}^{k-1} \|w_{I(\kappa+1,t,s)} - w_{I(\kappa,t,s)}\| \leq \sum_{\eta \in \{0,\ldots,t-1\}\setminus\{I(0,t,s)\}} \|w_{\eta+1} - w_{\eta}\| + \eta r_0 \leq \sum_{\eta \in \{0,\ldots,t-1\}\setminus\{I(0,t,s)\}} \|w_{\eta+1} - w_{\eta}\| + \eta^2 \lambda K r_0.
\]

Also, $\sum_{\tau=0}^{t-1} \|w_I(0,\tau+1,s) - w_I(0,\tau, s)\|^2 = 0$.

Next, suppose that $s = s_0$ and $t > t_0$. Since $I(0, t, s) > I(k_0, t_0, s_0)$, $\|w_{I(k_0+1,t_0,s_0)} - w_{I(k_0,t_0,s_0)}\|$ does not appear in the two terms
\[
\sum_{\kappa=0}^{k-1} \frac{1}{b_{k+1}} \|w_{I(\kappa+1,t,s)} - w_{I(\kappa,t,s)}\|^2 \leq \frac{1}{b} \sum_{\kappa=0}^{k-1} \|w_{I(\kappa+1,t,s)} - w_{I(\kappa,t,s)}\|^2
\]
and
\[
\sum_{\kappa=0}^{k-1} \|w_{I(\kappa+1,t,s)} - w_{I(\kappa,t,s)}\|.
\]

Also, similar to Case I, since $I(k_0', t_0, s_0) > I(0, 0, s)$,
\[
\sum_{\tau=0}^{t-1} \|w_I(0,\tau+1,s) - w_I(0,\tau, s)\|^2 \leq 2K \sum_{\eta \in \{0,\ldots,t-1\}\setminus\{I(0,t_0,s_0)\}} \|w_{\eta+1} - w_{\eta}\|^2 + 2\eta^2 r_0^2 \]
\[
= 2K \sum_{\eta \in \{0,\ldots,t-1\}\setminus\{I(0,t_0,s_0)\}} \|w_{\eta+1} - w_{\eta}\|^2 + 2\eta^2 r_0^2.
\]

Finally, when $s > s_0$, $\|w_{\eta+1} - w_{\eta}\|$ never appears in the bound of $\|y_I\|$.  

36
Case III. $K < 1/(\eta \lambda) \leq KT$.

In this case, $\tilde{I} = I(0, t_0 + 1, s_0) - 1$. Since $I + 1 = I(k, t, s) > \tilde{I}$, if $s = s_0$, then we can see that $t \geq t_0 + 1 > t_0$. Then, $\|w_{I+1} - w_I\|$ does not appear in the two terms

$$\sum_{\kappa=0}^{k-1} \frac{1}{b_{\kappa+1}} \|w_{I(\kappa+1,t,s)} - w_{I(\kappa,t,s)}\| \leq \frac{1}{b} \sum_{\kappa=0}^{k-1} \|w_{I(\kappa+1,t,s)} - w_{I(\kappa,t,s)}\|^2$$

and

$$\sum_{\kappa=0}^{k-1} \|w_{I(\kappa+1,t,s)} - w_{I(\kappa,t,s)}\|.$$

Observe that

$$\sum_{\tau=0}^{t-1} \|w_{I(\tau+1,s)} - w_{I(\tau,s)}\|^2 = \sum_{\tau=0}^{t-1} \|w_{I(\tau+1,s)} - w_{I(\tau,s)}\|^2 + \|w_{I(0,t_0+1,s)} - w_{I(0,t_0,s)}\|^2$$

$$\leq K \sum_{i \in \{I(0,0,s), \ldots, I(0,t_0-1), I(0,t_0+1,s_0)\}} \|w_{i+1} - w_i\|^2$$

$$+ 2K \sum_{i \in \{I(0,t_0-1), I(0,t_0+1,s_0-2)\}} \|w_{i+1} - w_i\|^2 + 2\eta^2 r_0^2$$

$$\leq 2K \sum_{i \in \{I(0,0,s), \ldots, I(0,t_0-1)\}} \|w_{i+1} - w_i\|^2 + 2\eta^2 r_0^2.$$

When $s > s_0$, $\|w_{I+1} - w_I\|$ never appears in the bound of $\|y_{I+1}\|$.

Case IV. $KT < 1/(\eta \lambda)$.

In this case, $\tilde{I} = I(0,0,s_0+1) - 1$. Since $I + 1 = I(k, t, s) > \tilde{I}$, we know that $s \geq s_0 + 1 > s_0$. Hence, $\|w_{I+1} - w_I\|$ never appears in the bound of $\|y_{I+1}\|$.

In summary, we have

$$\|y_{I+1}\|$$

$$\leq \left\{ c \left( 8L^2 \left( \frac{1}{b} \sum_{i \in \{I(0,t,s), \ldots, I(k-1,t,s)\}} \|w_{i+1} - w_i\|^2 + \left( \frac{\eta^2 \lambda^2 K + 1/\sqrt{K}}{b} \eta^2 r_0^2 \right) \right) + 32K\rho^2 U^{2}_{\Delta} U w (I + 1)^2 + \bar{\varepsilon}^t \right\}$$

$$+ \left\{ \sum_{i \in \{I(0,t,s), \ldots, I(k-1,t,s)\}} \|w_{i+1} - w_i\| + \eta^2 \lambda K r_0 \right\} + 4\rho U^{2}_{\Delta} U w (I + 1)$$

$$+ \left\{ \sum_{i \in \{I(0,t,s), \ldots, I(k-1,t,s)\}} \|w_{i+1} - w_i\|^2 + 2\eta^2 r_0^2 \right\} + 32T\rho^2 U^{2}_{\Delta} U w (I + 1)^2 + \bar{\varepsilon}^t \right\}$$

$$\times \sqrt{\frac{2KTSd}{q} + \loglog \frac{8KTG}{\bar{\varepsilon}^t}}.$$
Then, we further bound the upper bound as follows:

\[
\|w_{I(\kappa+1, \tau, s)} - w_{I(\kappa, \tau, s)}\| = \left\| (1 - \eta)J_{I(\kappa+1, \tau, s) - I} \xi_\ell - \eta \sum_{i = \ell}^{I(\kappa, \tau, s)} (1 - \eta)J_{I(\kappa, \tau, s) - i} (\Delta_i w_i + y_i) \right\|
\]

\[
+ \eta \sum_{i = \ell}^{I(\kappa, \tau, s) - 1} (1 - \eta)J_{I(\kappa, \tau, s) - i} - (\Delta_i w_i + y_i) \right\|
\]

\[
= \left\| -\eta^2 \mathcal{H}(1 - \eta)J_{I(\kappa+1, \tau, s) - I} \xi_\ell \right\|
\]

\[
+ \eta \sum_{i = \ell}^{I(\kappa, \tau, s) - 1} \left( \eta^2 \mathcal{H}(1 - \eta)J_{I(\kappa, \tau, s) - i} - \eta \Delta_i w_i + y_i \right) \right\|
\]

\[
\leq \eta \left\| \mathcal{H}(1 - \eta)J_{I(\kappa+1, \tau, s) - I} \xi_\ell \right\|
\]

For the second inequality, we used the following two facts:

\[
\left\| \mathcal{H}(1 - \eta)J_{I(\kappa+1, \tau, s) - I} \xi_\ell \right\| \leq \eta \lambda(1 + \eta \lambda)J_{I(\kappa+1, \tau, s) - I} \xi_\ell
\]

\[
\left\| \mathcal{H}(1 - \eta)J_{I(\kappa+1, \tau, s) - I} \xi_\ell \right\| \leq \eta \lambda(1 + \eta \lambda)J_{I(\kappa+1, \tau, s) - I} \xi_\ell
\]

for \( J \in \mathbb{N} \cup \{0\} \). The former inequality holds because \( \xi_\ell = 2(\xi_\ell, e_{\min})_e \) and \( e_{\min} \) is the minimum eigenvector of \( \mathcal{H} \). The latter inequality is the direct result of the from Lemma B.1.

Then, we further bound the upper bound as follows:

\[
\|w_{I(\kappa+1, \tau, s)} - w_{I(\kappa, \tau, s)}\| \leq \eta^2 \lambda(1 + \eta \lambda)J_{I(\kappa+1, \tau, s) - I} \right\| \right\|
\]

\[
+ \eta \sum_{i = \ell}^{I(\kappa, \tau, s) - 1} \left( \eta^2 \mathcal{H}(1 - \eta)J_{I(\kappa+1, \tau, s) - i} - \eta \Delta_i w_i + y_i \right) \right\|
\]

\[
\leq \eta^2 \lambda(1 + \eta \lambda)J_{I(\kappa+1, \tau, s) - I} \right\| \right\|
\]

\[
+ 4e(1 + \log J)\eta PU_\Delta U_w(I) + 2e(1 + \log J)\eta (1 + \eta \lambda J)U_y(I).
\]

\[
\leq 4e(1 + \log J)\eta PU_\Delta U_w(I) + \left( \frac{1}{\epsilon_{\text{upper}}(L + \frac{\sqrt{KL}}{\nu_b} + K\zeta + \frac{\sqrt{KL}}{\sqrt{P_b}})} + 2e(1 + \log J)\eta (1 + \eta \lambda J) \right) U_y(I)
\]

\[
=: U_{w}(I).
\]

For the first inequality, we used \( \|\Delta_i\| \leq \rho U_\Delta \), the inductive assumptions on \( \|w_i\| \) and \( \|y_i\| \) for \( i \leq I(k, t, s) - 1 \) and \( \sum_{i = i_0}^{i'} 1/(i + 1 - i_0) \leq 1 + \log(i' + 1 - i_0) \) for \( i' \geq i_0 \).
Concretely, we computed
\[
\sum_{i=I}^{I(\kappa,\tau,s)-1} \left( \eta \lambda(1 + \eta \lambda)^{I(\kappa,\tau,s)-1-i} + \frac{e}{I(\kappa,\tau,s) - i} \right) \| \Delta w_i \|
\]
\[
\leq \sum_{i=I}^{I(\kappa,\tau,s)-1} \left( \eta \lambda(1 + \eta \lambda)^{I(\kappa,\tau,s)-1-i} + \frac{e}{I(\kappa,\tau,s) - i} \right) \rho U_{\Delta} U_w(i)
\]
\[
\leq \rho U_{\Delta}(1 + e(1 + \log J)) U_w(I)
\]
\[
\leq 2e(1 + \log J) \rho U_{\Delta} U_w(I).
\]

Also, we computed
\[
\sum_{i=I}^{I(\kappa,\tau,s)-1} \left( \eta \lambda(1 + \eta \lambda)^{I(\kappa,\tau,s)-1-i} + \frac{e}{I(\kappa,\tau,s) - i} \right) \| y_i \|
\]
\[
\leq \sum_{i=I}^{I(\kappa,\tau,s)-1} \left( \eta \lambda(1 + \eta \lambda)^{I(\kappa,\tau,s)-1-i} + \frac{e}{I(\kappa,\tau,s) - i} \right)
\]
\[
\times \left( c_{upper} \eta^2 \lambda \left( L + \frac{\sqrt{KL}}{\sqrt{b}} + K \zeta + \frac{\sqrt{KT}L}{\sqrt{Pb}} \right)(1 + \eta \lambda)^{i-\bar{T}r_0} \right)
\]
\[
\leq c_{upper} \eta^3 \lambda^2 J \left( L + \frac{\sqrt{KL}}{\sqrt{b}} + K \zeta + \frac{\sqrt{KT}L}{\sqrt{Pb}} \right)(1 + \eta \lambda)^{I(\kappa,\tau,s)-1-\bar{T}r_0}
\]
\[
+ c_{upper} e(1 + \log J) \eta^2 \lambda \left( L + \frac{\sqrt{KL}}{\sqrt{b}} + K \zeta + \frac{\sqrt{KT}L}{\sqrt{Pb}} \right)(1 + \eta \lambda)^{I(\kappa,\tau,s)-1-\bar{T}r_0}
\]
\[
\leq e(1 + \log J)(1 + \eta \lambda) U_y(I).
\]

Using the bound of \( \| w_{I(\kappa+1,\tau,s)} - w_{I(\kappa,\tau,s)} \| \), we get

\[
\| y_{I+1} \|
\]
\[
\leq \left\{ c \left( \frac{8L^2}{b} U_w(I) + \frac{\eta^2 \lambda^2 K + 1/\sqrt{K}}{b} \eta^2 r_0^2 \right) + 32K \rho^2 U_{\Delta}^2 U_w(I + 1)^2 + \varepsilon^2
\]
\[
+ \zeta \left( KU_w(I) + \eta^2 \lambda K r_0 \right) + 4\rho U_{\Delta} U_w(I + 1)
\]
\[
+ \frac{e}{\sqrt{PKb}} \sqrt{8L^2 (2K^2 T U_w(I) + 2\eta^2 r_0^2)} + 32T \rho^2 U_{\Delta}^2 U_w(I + 1)^2 + \varepsilon \right\}
\]
\[
\times \sqrt{\log \frac{2KTSd}{q} + \log \log \frac{8KTG}{\varepsilon^7}}
\]
\[
\leq \left\{ \left( \frac{2\sqrt{2}c\sqrt{KL}}{\sqrt{b}} + K \zeta + \frac{4c\sqrt{KT}L}{\sqrt{PKb}} \right) U_w(I) + \left( \frac{2\sqrt{2}c\eta\lambda\sqrt{KL}}{\sqrt{b}} + \frac{2\sqrt{2}cL}{K^{1/4}\sqrt{b}} + \eta \lambda K \zeta + \frac{4cL}{\sqrt{PKb}} \right) r_0
\]
\[
+ \left( \frac{4\sqrt{2}c\sqrt{KL}}{\sqrt{b}} + 4 + \frac{4\sqrt{2}c\sqrt{T}}{\sqrt{PKb}} \right) \rho U_{\Delta} U_w(I + 1) + 2c\sqrt{\varepsilon} \right\}
\]
\[
\times \sqrt{\log \frac{2KTSd}{q} + \log \log \frac{8KTG}{\varepsilon^7}}
\]

39
Under $b \geq 1/(K^{1/2}\lambda \sqrt{b} + K\zeta + \sqrt{KL}/\sqrt{Pb})$, from $\lambda \geq \sqrt{P\varepsilon}$, we have
\[
\frac{2\sqrt{2c}e\lambda \sqrt{KL}}{\sqrt{b}} + \frac{2\sqrt{2c}L}{K^{1/4}\sqrt{b}} + \eta \lambda \zeta + \frac{4cL}{\sqrt{PKb}} \\
\leq \eta \left(\frac{2\sqrt{2c}e\sqrt{KL}}{\sqrt{b}} + 2\sqrt{2c} \left( L + \frac{\sqrt{KL}}{\sqrt{b}} + \frac{\sqrt{KL}}{\sqrt{Pb}} \right) \right) + K\zeta + 4c \left( L + \frac{\sqrt{KL}}{\sqrt{b}} + \frac{\sqrt{KL}}{\sqrt{Pb}} \right) \lambda \\
\leq 12c\eta \left( L + \frac{\sqrt{KL}}{\sqrt{b}} + K\zeta + \frac{\sqrt{KL}}{\sqrt{Pb}} \right) \lambda.
\]
Also, under $b \geq K$ and $b \geq T/(PK)$, we have
\[
\frac{4\sqrt{2c}\sqrt{KL}}{\sqrt{b}} + 4 + \frac{4\sqrt{2c}\sqrt{T}}{\sqrt{PKb}} \leq 24c.
\]
We choose $\bar{\varepsilon}$ such that $\varepsilon' \leq \eta^4 L^2 \lambda^2 r_0^2 / (64(\log \frac{2KTSd}{q} + \log \log \frac{8KTL}{\varepsilon'}c^2))$. Then, it holds that
\[
\| y_{t+1} \| \leq \left\{ 4c \left( \frac{\sqrt{KL}}{\sqrt{b}} + K\zeta + \frac{\sqrt{KL}}{\sqrt{Pb}} \right) U_w(I) + 12c\eta \left( L + \frac{\sqrt{KL}}{\sqrt{b}} + K\zeta + \frac{\sqrt{KL}}{\sqrt{Pb}} \right) \eta \lambda r_0 \\
+ 24c\rho U\Delta U_w(I + 1) \right\} \times \sqrt{\log \frac{2KTSd}{q} + \log \log \frac{8KTL}{\varepsilon'} + 0.25U_y(I + 1)}.
\]
From the definition of $U_w(I)$:
\[
U_w(I) := 4c(1 + \log J)\eta\rho U\Delta U_w(I) + \left( \frac{1}{c_{\text{upper}}(y)} \left( L + \frac{\sqrt{KL}}{\sqrt{b}} + K\zeta + \frac{\sqrt{KL}}{\sqrt{Pb}} \right) \left( 1 + \log J \right) \eta + \lambda \right) U_y(I),
\]
we get
\[
\| y_{t+1} \| \leq \left\{ 4c \left( \frac{1}{c_{\text{upper}}(y)} + 2c(1 + \log J)\eta \left( \frac{\sqrt{KL}}{\sqrt{b}} + K\zeta + \frac{\sqrt{KL}}{\sqrt{Pb}} \right) \right) \left( 1 + \log J \right) \eta + \lambda \right) U_y(I) \\
+ 12c\eta \left( L + \frac{\sqrt{KL}}{\sqrt{b}} + K\zeta + \frac{\sqrt{KL}}{\sqrt{Pb}} \right) \eta \lambda r_0 \\
+ \left( 24c + 16c(1 + \log J)\eta \left( \frac{\sqrt{KL}}{\sqrt{b}} + K\zeta + \frac{\sqrt{KL}}{\sqrt{Pb}} \right) \right) \rho U\Delta U_w(I + 1) \right\} \\
\times \sqrt{\log \frac{2KTSd}{q} + \log \log \frac{8KTL}{\varepsilon'} + 0.25U_y(I + 1)}.
\]
From the definitions of $J$ and $U$ with $r = c_r \varepsilon$ with $c_r = \tilde{O}(1)$, we have
\[
\rho U\Delta U_w(I) \leq \rho U\Delta \left( \frac{c_{\text{upper}}(y)}{c_{\text{upper}}(y)} \left( L + \frac{\sqrt{KL}}{\sqrt{b}} + K\zeta + \frac{\sqrt{KL}}{\sqrt{Pb}} \right) \right) U_y(I + 1) \\
\leq \frac{4c_r \sqrt{e} + 2c_r J \rho \varepsilon}{\eta^2} \left( \frac{c_{\text{upper}}(y)}{c_{\text{upper}}(y)} \left( L + \frac{\sqrt{KL}}{\sqrt{b}} + K\zeta + \frac{\sqrt{KL}}{\sqrt{Pb}} \right) \right) U_y(I + 1) \\
\leq \frac{4c_r \sqrt{e} + 2c_r J}{\eta} \left( L + \frac{\sqrt{KL}}{\sqrt{b}} + K\zeta + \frac{\sqrt{KL}}{\sqrt{Pb}} \right) U_y(I + 1).
\]
Here, for the last inequality, we used \( \lambda \geq \sqrt{\rho} \) and \( c_{\text{upper}} = c_{\text{upper}}^{(w)} \).

Therefore, we arrive at

\[
\|y_{t+1}\| \leq \begin{cases} 
4c \left( \frac{1}{c_{\text{upper}}^{(y)}} + 2c(1 + \log J) \eta \left( \frac{\sqrt{KL}}{\sqrt{b}} + K\zeta + \frac{\sqrt{KTL}}{\sqrt{Pb}} \right)(1 + \eta\lambda J) \right) U_y(I) \\
+ \frac{12c}{c_{\text{upper}}^{(y)}} U_y(I + 1) \\
+ \left( \frac{96ccr + 2cJ}{\eta (L + \sqrt{KL}/\sqrt{b} + K\zeta + \sqrt{KTL}/\sqrt{Pb})} + 64c(1 + \log J)c_r\sqrt{c_f + 2cJ} \right) U_y(I + 1) \\
\times \sqrt{\log \frac{2KTSd}{\eta} + \log \frac{8KTG}{\epsilon^2}} + 0.25U_y(I + 1).
\]

We set \( c_{\text{upper}}^{(y)} = c_{\text{upper}}^{(w)} = \max \{3, 48c\sqrt{\log \frac{2KTSd}{\eta} + \log \log \frac{8KTG}{\epsilon^2}} \} \). Then, since \( \eta\lambda J \leq c_J \), if we choose \( \eta \) such that \( \eta(L + \sqrt{KL}/\sqrt{b} + K\zeta + \sqrt{KTL}/\sqrt{Pb}) \leq 1/\left(48ce(1 + cJ)(1 + \log J)\sqrt{\log \frac{2KTSd}{\eta} + \log \log \frac{8KTG}{\epsilon^2}} \right) \), the first term can be bounded by \( 0.25U_y(I + 1) \).

Next, we can choose \( \eta \) such that \( \eta(L + \sqrt{KL}/\sqrt{b} + K\zeta + \sqrt{KTL}/\sqrt{Pb}) \geq \hat{\Theta}(\sqrt{\zeta} + 1/(c_J)) \). Then if we appropriately choose \( c_r \leq \hat{O}(\sqrt{\zeta} + 1/(c_J))/\sqrt{c_f + 2cJ} \), the third term can be bounded by \( 0.25U_y(I + 1) \). Therefore, we conclude that

\[ \|y_{t+1}\| \leq U_y(I + 1). \]

This finishes the proof of the mathematical induction.

Let \( \tilde{\mathcal{J}} := \mathcal{J} - (I - I(k_0, t_0, s_0)) \). From \( \text{[9]}, \text{[12]} \text{ and } \text{[13]} \), we have

\[
\|w_{I(k_0, t_0, s_0) + \tilde{\mathcal{J}}}\| = \left\| \eta(1 - \eta\mathcal{H})^{\tilde{\mathcal{J}}} \tilde{\xi}_I - \eta \sum_{i=I}^{I+\tilde{\mathcal{J}}} (1 - \eta\mathcal{H})^{\tilde{\mathcal{J}} - i} (\Delta_i w_i + y_i) \right\|
\geq \left\| \eta(1 - \eta\mathcal{H})^{\tilde{\mathcal{J}}} \tilde{\xi}_I \right\|
- \left\| \eta \sum_{i=I}^{I+\tilde{\mathcal{J}}} (1 - \eta\mathcal{H})^{\tilde{\mathcal{J}} - i} \Delta_i w_i \right\|
- \left\| \eta \sum_{i=I}^{I+\tilde{\mathcal{J}}} (1 - \eta\mathcal{H})^{\tilde{\mathcal{J}} - i} y_i \right\|
\geq \eta(1 + \lambda)\tilde{\mathcal{J}} r_0 - \frac{1}{3c_{\text{upper}}^{(w)}} U_w(I(k_0, t_0, s_0) + \mathcal{J})
= \frac{2\eta(1 + \lambda)^{\tilde{\mathcal{J}}} r_0}{3}.
\]

Now, we define \( c_{\mathcal{J}} \) as the minimum positive number that satisfies

\[ c_{\mathcal{J}} \geq 1 + 2\log(48\sqrt{c_f + 2\mathcal{J}} \sqrt{d}/q). \]

From \( \text{[6]} \), we can see that

\[ \frac{2\eta(1 + \lambda)^{\tilde{\mathcal{J}}} r_0}{3} \geq 4\Delta. \]
This is because we have
\[
\log \left( (1 + \eta \lambda)^{\frac{3}{2}} \right) = \mathcal{J} \log(1 + \eta \lambda) \\
\geq \mathcal{J} \left( 1 - \frac{1}{1 + \eta \lambda} \right) \\
\geq \frac{\eta \lambda \mathcal{J}}{2} \\
\geq \frac{\eta \lambda (\mathcal{J} - 1/(\eta \lambda))}{2} \\
= \frac{c_J - 1}{2} \\
\geq \log(4\sqrt{c_J} + 2\mathcal{J}d/q)
\]

and thus
\[
\frac{2\eta(1 + \eta \lambda)^{\frac{3}{2}}}{3} x_0 \geq \frac{\eta(1 + \eta \lambda)^{\frac{3}{2}} q r}{3\sqrt{d}} \\
\geq 4 \times 4\sqrt{c_J} + 2\eta \mathcal{J} r = 4\Delta.
\]

Here, the first inequality holds from (6). This contradicts with \( \|w_{I(0, t_0, s_0)}\| \leq 2\Delta \).

**Proof of Proposition 4.3**

Now, we prove Proposition 4.3. Combining Proposition 4.3 with Proposition B.4, we have
\[
\min \{ f(x_{I(0, t_0, s_0)} + J_{I(0, t_0, s_0)}), f(x_0'), f(x_{I(0, t_0, s_0)} + J_{I(0, t_0, s_0)}) - f(x_0') \} \\
\leq -J_{I(0, t_0, s_0)} \\
+ \frac{2\eta}{\eta} \left( J(I, d_0, s_0) \right. \\
\left. + \frac{K}{K} \sum_{i=I(0, t_0, s_0)}^{I(d_0, s_0)-1} \|x_{i+1} - x_i\|^2 + \frac{J(I, d_0, s_0)}{K} \sum_{i=I(0, t_0, s_0)}^{I(d_0, s_0)-1} \|x_{i+1} - x_i\|^2 \right).
\]

with probability at least 1 - 9q.

Finally, since \( \{x_i\}_{I=0}^{KTS} \) has the same marginal distribution as \( \{x_i'\}_{I=0}^{KTS} \), we conclude that
\[
f(x_{I(0, t_0, s_0)} + J_{I(0, t_0, s_0)}), f(x_0') \\
\leq -J_{I(0, t_0, s_0)} \\
+ \frac{2\eta}{\eta} \left( J(I, d_0, s_0) \right. \\
\left. + \frac{K}{K} \sum_{i=I(0, t_0, s_0)}^{I(d_0, s_0)-1} \|x_{i+1} - x_i\|^2 + \frac{J(I, d_0, s_0)}{K} \sum_{i=I(0, t_0, s_0)}^{I(d_0, s_0)-1} \|x_{i+1} - x_i\|^2 \right).
\]

with probability at least 1/2 - 9q/2. This finishes the proof of Proposition 4.3.

**B.5 Finding Second Order Stationary Points**

Let \( \mathcal{R}_1 := \{ x \in \mathbb{R}^d \| \nabla f(x) \| > \varepsilon \} \), \( \mathcal{R}_2 := \{ x \in \mathbb{R}^d \| \nabla f(x) \| \leq \varepsilon \wedge \lambda_{\min}(\nabla^2 f(x)) < -\sqrt{\varepsilon} \}
\)

and \( \mathcal{R}_3 := \mathbb{R}^d \setminus (\mathcal{R}_1 \cup \mathcal{R}_2) = \{ x \in \mathbb{R}^d \| \nabla f(x) \| \leq \varepsilon \wedge \lambda_{\min}(\nabla^2 f(x)) \geq -\sqrt{\varepsilon} \} \).

We define
\[
t_{m+1} = \begin{cases} 
  t_m + 1, & \text{if } \bar{x}_{t_m} \in \mathcal{R}_1 \cup \mathcal{R}_3 \\
  t_m + \bar{x}_{t_m}, & \text{if } \bar{x}_{t_m} \in \mathcal{R}_2
\end{cases}
\]

with \( t_1 = 0 \). Note that \( J_{t_m} \leq c_J/(\eta\sqrt{\varepsilon}) \). Let \( M := \min \{ m \in \mathbb{N} | E[t_m] \geq KTS/8 \} \). Observe that \( t_M \leq M \times c_J/(\eta\sqrt{\varepsilon}) \leq (KTS/8) \times c_J/(\eta\sqrt{\varepsilon}) \) because \( t_{KTS/8} \geq KTS/8 \) always.
holds. We define $\hat{S}$ as the minimum number that satisfies $\hat{S} \geq (S/8) \times e_f/(\eta \sqrt{p})$ \textup{w} S \textwedge \textwedge S with $S = \Theta(1 + (f(\bar{x}_0) - f(x_*)/(\eta KT \varepsilon^2))$, where in the definition of $\eta$ we set $S \leftarrow \hat{S}$. Then $\iota_M \leq KTS \bar{S}$ always holds. We will use Propositions \ref{prop:4.1} and \ref{prop:4.3} with $S \leftarrow \hat{S}$, $s(t_m)$ denotes the maximum natural number $t'$ satisfying $\iota_m \geq I \in P_1(0,0,\iota_m)$, and $R(t_m)$ denotes the maximum natural number $t'$ satisfying $\iota_m \geq I \in P_1(0,0,\iota_m)$. We will show that $\bar{x}_i \in R_3$ for some $i \in \{KTS \cup \{0\}$ with probability at least $1/2$. Let $E_i$ be the event that $\bar{x}_i \notin R_3$ for all $i \leq i$ for $i \in \{KTS \cup \{0\}$. Note that $E_i \subset E_i$ for every $i$. We can say that the objective of this section is to show $P(E_{KTS}) \leq 1/2$.

\textbf{Proposition B.5.} Suppose that Assumptions \ref{assumption:2} \textwedge \ref{assumption:2} \textwedge \ref{assumption:2} \textwedge \ref{assumption:2} and \ref{assumption:3} hold. Under $K = O(L/\zeta \land b \land P_b/T)$, if we appropriately choose $\eta = \Theta(1/L \land 1/(K \zeta) \land \sqrt{b}/(K \zeta) \land \sqrt{P_b}/(\sqrt{KT}L))$ and $r = \Theta(\varepsilon)$, then it holds

\[
\frac{7\eta}{312} E[t_M] \varepsilon^2 \leq f(\bar{x}_0) - f(x_*) + \frac{\eta}{64} \sum_{m=1}^{M-1} P(\bar{x}_m \in R_3) \varepsilon^2.
\]

\textbf{Proof of Proposition B.5}

First, we consider the difference $E[f(x_{m+1}) - f(x_m)]$.

**Bounding** $E[f(x_{m+1}) - f(x_m)|x_m \in R_1]$

Let $H_1$ be the event where \ref{eq:4.3} with $I(k_0,t_0,s_0) \leftarrow \iota_m$ and $I(k,t,s) \leftarrow \iota_{m+1}$ holds. Note that $P(H_1|x_m \in R_1) \geq 1 - 3q$. From Proposition \ref{prop:4.3} and \ref{prop:5.9}, we have for every $q \in (0,1/6)$,

\[
E[f(x_{m+1}) - f(x_m)|x_m \in R_1] = E[f(x_{m+1}) - f(x_m)|x_m \in R_1, H_1]P(H_1|x_m \in R_1) + E[f(x_{m+1}) - f(x_m)|x_m \in R_1, H_1^c]P(H_1^c|x_m \in R_1)
\]

\[
\leq - (1 - 3q) \frac{\eta}{2} E[\|f(x_m)\|^2|x_m \in R_1, H_1] + \eta r^2
\]

\[
+ \frac{c_n}{\eta} E \left[ \frac{(t_m + 1 - t_m) \land K}{K} \sum_{i=I(0,t(t_m),s(t_m))}^{t_m} \|x_{i+1} - x_i\|^2 \right.
\]

\[
+ \frac{(t_m + 1 - t_m) \land KT}{KT} \sum_{i=I(0,t(t_m),s(t_m))}^{t_m} \|x_{i+1} - x_i\|^2|\bar{x}_m \in R_1, H_1 \right] P(H_1|x_m \in R_1)
\]

\[
+ 3q \times 36\eta K^2 T^2 S(G^2 + r^2)
\]

\[
\leq - \frac{\eta}{8} r^2 + 2\eta r^2
\]

\[
+ \frac{c_n}{\eta} E \left[ \frac{(t_m + 1 - t_m) \land K}{K} \sum_{i=I(0,t(t_m),s(t_m))}^{t_m} \|x_{i+1} - x_i\|^2 \right.
\]

\[
+ \frac{(t_m + 1 - t_m) \land KT}{KT} \sum_{i=I(0,t(t_m),s(t_m))}^{t_m} \|x_{i+1} - x_i\|^2|\bar{x}_m \in R_1, H_1 \right] P(H_1|x_m \in R_1)
\]

\[
+ 3q \times 36\eta K^2 T^2 S(G^2 + r^2)
\]

\[
\leq - \frac{\eta}{8} r^2 + 2\eta r^2
\]

\[
+ \frac{c_n}{\eta} E \left[ \frac{(t_m + 1 - t_m) \land K}{K} \sum_{i=I(0,t(t_m),s(t_m))}^{t_m} \|x_{i+1} - x_i\|^2 \right.
\]

\[
+ \frac{(t_m + 1 - t_m) \land KT}{KT} \sum_{i=I(0,t(t_m),s(t_m))}^{t_m} \|x_{i+1} - x_i\|^2|\bar{x}_m \in R_1 \right] P(H_1|x_m \in R_1)
\]

\[
+ 3q \times 36\eta K^2 T^2 S(G^2 + r^2)
\]
For the second inequality, we used $1/(1 - 3q) \leq 1/2$ and $-\|\nabla f(x_{I(k,t,s)})\|^2 \leq -(1/2)\|\nabla f(x_{I(k,t,s)})\|^2 + \|\nabla f(x_{I(k,t,s)}) - f(x_{I(k,t,s)})\|^2 \leq -(1/2)\|\nabla f(x_{I(k,t,s)})\|^2 + \eta^2 L^2 \eta^2 \leq -(1/2)\|\nabla f(x_{I(k,t,s)})\|^2 + \eta^2$

Thus, setting $q := (\eta \varepsilon^2/16)/(96K^2 T^2 S(G^2 + \eta^2))$ and $c_r \leq 1/\sqrt{96}$, we get

$$\mathbb{E}[f(x_{t+1}) - f(x_t) | \bar{x}_t \in \mathcal{R}_1]$$

$$\leq -\frac{\eta}{16}\varepsilon^2 + 3\eta^2$$

$$+ \frac{c_0}{\eta} \mathbb{E} \left[ \frac{(m+1 - m) K}{K} \sum_{i = I(0,t(m),s(m))}^{t_m} \|x_{i+1} - x_i\|^2 \right]$$

$$+ \frac{(m+1 - m) KT}{K} I(0,t(m),s(m)) - 1 \sum_{i = I(0,0,s(m))}^{t_m} \|x_{i+1} - x_i\|^2$$

$$\leq -\frac{\eta}{32} \mathbb{E}[t_{m+1} - t_m | \bar{x}_m \in \mathcal{R}_1] \varepsilon^2$$

$$+ \frac{c_0}{\eta} \mathbb{E} \left[ \frac{(m+1 - m) K}{K} \sum_{i = I(0,t(m),s(m))}^{t_m} \|x_{i+1} - x_i\|^2 \right]$$

$$+ \frac{(m+1 - m) KT}{K} I(0,t(m),s(m)) - 1 \sum_{i = I(0,0,s(m))}^{t_m} \|x_{i+1} - x_i\|^2$$

$$\in \mathcal{R}_1 \right). \text{(17)}$$

Here, we used $\mathbb{E}[t_{m+1} - t_m | \bar{x}_m \in \mathcal{R}_1] = 1.$

Bounding $\mathbb{E}[f(x_{t+1}) - f(x_t) | \bar{x}_m \in \mathcal{R}_2]$

$H_2$ denotes the event where $\{16\}$ with $I(k_0, t_0, s_0) \leftarrow t_m$ holds. Note that $\mathbb{P}(H_2 | \bar{x}_m \in \mathcal{R}_2) \geq 1/2 - 7q/2$ by Proposition 4.3. Let $q \in (0, 1/14)$ and with $c_r \geq 16$. We will use Proposition 4.3 (8) and (5).

$$\mathbb{E}[f(x_{t+1}) - f(x_t) | \bar{x}_m \in \mathcal{R}_2]$$

$$= \mathbb{E}[f(x_{t+1}) - f(x_t) | \bar{x}_m \in \mathcal{R}_2, H_2] \mathbb{P}(H_2 | \bar{x}_m \in \mathcal{R}_2)$$

$$+ \mathbb{E}[f(x_{t+1}) - f(x_t) | \bar{x}_m \in \mathcal{R}_2, H_1, H_2^c] \mathbb{P}(H_1, H_2^c | \bar{x}_m \in \mathcal{R}_2)$$

$$+ \mathbb{E}[f(x_{t+1}) - f(x_t) | \bar{x}_m \in \mathcal{R}_2, H_1^c, H_2^c] \mathbb{P}(H_1^c, H_2^c | \bar{x}_m \in \mathcal{R}_2).$$

The first term can be bounded as

$$\mathbb{E}[f(x_{t+1}) - f(x_t) | \bar{x}_m \in \mathcal{R}_2, H_2]$$

$$\leq \left\{ -\mathbb{E}[\mathcal{F}_m | \bar{x}_m \in \mathcal{R}_2, H_2] \right\}$$

$$+ \frac{2c_0}{\eta} \mathbb{E} \left[ \frac{(m+1 - m) K}{K} \sum_{i = I(0,t(m),s(m))}^{t_m} \|x_{i+1} - x_i\|^2 \right]$$

$$+ \frac{(m+1 - m) KT}{K} I(0,t(m),s(m)) - 1 \sum_{i = I(0,0,s(m))}^{t_m} \|x_{i+1} - x_i\|^2.$$
Here, the inequality holds from Proposition 4.3. The second term can be bounded as

\[
\mathbb{E}[f(x_{i_{m+1}}) - f(x_{i_m})|x_{i_m} \in \mathcal{R}_2, H_1, H_2] P(H_1, H_2|x_{i_m} \in \mathcal{R}_2) \\
\leq \left\{ \frac{2}{c_F} \mathbb{E}[\mathcal{F}_{i_m}|x_{i_m} \in \mathcal{R}_2, H_1, H_2] \\
+ \frac{c_\eta}{\eta} \left[ \frac{(t_{m+1} - t_m) \wedge K}{K} \sum_{i=I(0,t_{i_m}),s(t_m)}^{t_{m-1}} \|x_{i+1} - x_i\|^2 \right. \\
+ \frac{(t_{m+1} - t_m) \wedge KT}{KT} \sum_{i=I(0,0,s(t_m))}^{I(0,t_{i_m}),s(t_m)-1} \|x_{i+1} - x_i\|^2|x_{i_m} \in \mathcal{R}_2, H_1, H_2 \right\} P(H_1, H_2|x_{i_m} \in \mathcal{R}_2).
\]

Here, we used (8).

Finally, the last term can be bounded as

\[
\mathbb{E}[f(x_{i_{m+1}}) - f(x_{i_m})|x_{i_m} \in \mathcal{R}_2, H_1^G, H_2^G] P(H_1^G, H_2^G|x_{i_m} \in \mathcal{R}_2) \\
\leq 36\eta K^2 T^2 S(G^2 + r^2) P(H_1^G, H_2^G|x_{i_m} \in \mathcal{R}_2).
\]

From these bounds, we have

\[
\mathbb{E}[f(x_{i_{m+1}}) - f(x_{i_m})|x_{i_m} \in \mathcal{R}_2] \\
\leq \left\{ \frac{2}{c_F} \mathbb{E}[\mathcal{F}_{i_m}|x_{i_m} \in \mathcal{R}_2] \\
+ \frac{3c_\eta}{\eta} \left[ \frac{(t_{m+1} - t_m) \wedge K}{K} \sum_{i=I(0,t_{i_m}),s(t_m)}^{t_{m-1}} \|x_{i+1} - x_i\|^2 \right. \\
+ \frac{(t_{m+1} - t_m) \wedge KT}{KT} \sum_{i=I(0,0,s(t_m))}^{I(0,t_{i_m}),s(t_m)-1} \|x_{i+1} - x_i\|^2|x_{i_m} \in \mathcal{R}_2 \right\} \mathbb{E}[\mathcal{F}_{i_m}|x_{i_m} \in \mathcal{R}_2] \\
\leq - \frac{c_F c^2 \eta}{8} \mathbb{E}[\mathcal{F}_{i_m}|x_{i_m} \in \mathcal{R}_2] \varepsilon^2 \\
+ \frac{3c_\eta}{\eta} \left[ \frac{(t_{m+1} - t_m) \wedge K}{K} \sum_{i=I(0,t_{i_m}),s(t_m)}^{t_{m-1}} \|x_{i+1} - x_i\|^2 \right. \\
+ \frac{(t_{m+1} - t_m) \wedge KT}{KT} \sum_{i=I(0,0,s(t_m))}^{I(0,t_{i_m}),s(t_m)-1} \|x_{i+1} - x_i\|^2|x_{i_m} \in \mathcal{R}_2 \right\} \mathbb{E}[\mathcal{F}_{i_m}|x_{i_m} \in \mathcal{R}_2] \\
+ 3q \times 36\eta K^2 T^2 S(G^2 + r^2) \mathbb{E}[\mathcal{F}_{i_m}|x_{i_m} \in \mathcal{R}_2] \varepsilon^2
\]

Here, for the first inequality, we used the facts that \( \mathcal{F}_{i_m} \) only depends on the start point \( x_{i_m} \in \mathcal{R}_2 \) and does not depend on \( H_2 \), which only captures the randomness after iteration index \( t_m \), and \( P(H_2|x_{i_m} \in \mathcal{R}_2, E_{i_m}) \geq 1/2 - 7\eta/2 \). For the last inequality, we used \( F_{I(0,t,s)} = c_F \eta \mathcal{F}_t(r)_s^2 \) with \( c_F \geq 16 \) and \( r = c_r \varepsilon^2 \).
Thus, setting $q := (c_F c_t^2 \eta^2 / 16) / (96K^2 T^2 S (G^2 + \eta^2))$, we get

\[
\begin{align*}
    \mathbb{E}[f(x_{t+1}^m) - f(x_t^m) | \bar{x}_{t+m} \in \mathcal{R}_2] \\
    \leq & \ - \frac{c_F c_t^2 \eta}{8} \mathbb{E}[J_{t,m} | \bar{x}_{t+m} \in \mathcal{R}_2] \varepsilon^2 \\
    & + 3c_F c_t^2 \eta \mathbb{E} \left[ \frac{(t_{m+1} - t_m) \wedge K}{K} \sum_{i=I(0,t_l(t_m),s(t_m))}^{t_{m-1}} \|x_i - x_i\|^2 \right] \\
    & + \frac{(t_{m+1} - t_m) \wedge KT}{KT} \mathbb{E} \left[ I(0,t_l(t_m),s(t_m))^{-1} \sum_{i=I(0,0,s(t_m))}^{t_{m-1}} \|x_i - x_i\|^2 | \bar{x}_{t+m} \in \mathcal{R}_2 \right] \\
    & + \frac{c_F c_t^2 \eta \varepsilon^2}{16}
\end{align*}
\]

Bounding $\mathbb{E}[f(x_{t+1}^m) - f(x_t^m) | \bar{x}_{t+m} \in \mathcal{R}_3]$

Similar to the arguments for bounding $\mathbb{E}[f(x_{t+1}^m) - f(x_t^m) | \bar{x}_{t+m} \in \mathcal{R}_1]$, we have

\[
\begin{align*}
    \mathbb{E}[f(x_{t+1}^m) - f(x_t^m) | \bar{x}_{t+m} \in \mathcal{R}_3] \\
    \leq & \ 3\eta^2 + \frac{c_F c_t^2 \eta}{\eta} \mathbb{E} \left[ \frac{(t_{m+1} - t_m) \wedge K}{K} \sum_{i=I(0,t_l(t_m),s(t_m))}^{t_{m-1}} \|x_i - x_i\|^2 \right] \\
    & + \frac{(t_{m+1} - t_m) \wedge KT}{KT} \mathbb{E} \left[ I(0,t_l(t_m),s(t_m))^{-1} \sum_{i=I(0,0,s(t_m))}^{t_{m-1}} \|x_i - x_i\|^2 | \bar{x}_{t+m} \in \mathcal{R}_3 \right] \\
    = & \ - \left( \frac{\eta}{32} \wedge \frac{c_F c_t^2 \eta}{16} \right) \mathbb{E}[t_{m+1} - t_m | \bar{x}_{t+m} \in \mathcal{R}_3] + \frac{\eta}{32} \wedge \frac{c_F c_t^2 \eta}{16} + 3\eta^2 \\
    & + \frac{c_F c_t^2 \eta}{\eta} \mathbb{E} \left[ \frac{(t_{m+1} - t_m) \wedge K}{K} \sum_{i=I(0,t_l(t_m),s(t_m))}^{t_{m-1}} \|x_i - x_i\|^2 \right] \\
    & + \frac{(t_{m+1} - t_m) \wedge KT}{KT} \mathbb{E} \left[ I(0,t_l(t_m),s(t_m))^{-1} \sum_{i=I(0,0,s(t_m))}^{t_{m-1}} \|x_i - x_i\|^2 | \bar{x}_{t+m} \in \mathcal{R}_3 \right].
\end{align*}
\]  

Here, we used the fact that $\mathbb{E}[t_{m+1} - t_m | \bar{x}_{t+m} \in \mathcal{R}_3] \mathbb{P}(\bar{x}_{t+m} \in \mathcal{R}_3) = \mathbb{P}(\bar{x}_{t+m} \in \mathcal{R}_3)$.  

46
Hence, combining (17), (18) and (19) yields

\[
\mathbb{E}[f(x_{t_{m+1}}) - f(x_{t_m})] \\
\leq - \left( \frac{\eta}{32} + \frac{c_\epsilon \gamma^2}{16} \right) \mathbb{E}[\epsilon_{t_{m+1}} - \epsilon_t] + \left( \frac{\eta}{32} \wedge \frac{c_\epsilon \gamma^2}{16} + 3\epsilon_r^2 \right) \mathbb{P}(\overline{x}_{t_m} \in \mathcal{R}_3) \epsilon^2 \\
+ \frac{3c_\eta}{\eta} \left[ \frac{(\epsilon_{t_{m+1}} - \epsilon_t) \wedge K}{K} \sum_{i = I(0, t(m), s(m))} \|x_{i+1} - x_i\|^2 \\
+ \frac{(\epsilon_{t_{m+1}} - \epsilon_t) \wedge K}{K} \sum_{i = I(0, t(m), s(m))} \|x_{i+1} - x_i\|^2 \\
+ \frac{(\epsilon_{t_{m+1}} - \epsilon_t) \wedge K}{K} \sum_{i = I(0, t(m), s(m))} \|x_{i+1} - x_i\|^2 \right] \\
\leq - \frac{c_\epsilon \gamma^2}{16} \mathbb{E}[\epsilon_{t_{m+1}} - \epsilon_t] + \left( \frac{c_\epsilon \gamma^2}{16} + 3\epsilon_r^2 \right) \mathbb{P}(\overline{x}_{t_m} \in \mathcal{R}_3) \epsilon^2 \\
+ \frac{3c_\eta}{\eta} \left[ \frac{(\epsilon_{t_{m+1}} - \epsilon_t) \wedge K}{K} \sum_{i = I(0, t(m), s(m))} \|x_{i+1} - x_i\|^2 \\
+ \frac{(\epsilon_{t_{m+1}} - \epsilon_t) \wedge K}{K} \sum_{i = I(0, t(m), s(m))} \|x_{i+1} - x_i\|^2 \right].
\]

under \(c_r \leq 1/\sqrt{2}\gamma^2\). Summing this inequality from \(m = 1\) to \(M - 1\) results in

\[
\mathbb{E}[f(x_{t_{M+1}}) - f(x_0)] \\
\leq - \frac{c_\epsilon \gamma^2}{16} \mathbb{E}[\epsilon_{t_{M+1}}] + \left( \frac{c_\epsilon \gamma^2}{16} + 3\epsilon_r^2 \right) \mathbb{P}(\overline{x}_{t_m} \in \mathcal{R}_3) \epsilon^2 \\
+ \frac{3c_\eta}{\eta} \left[ \frac{M-1}{M} \frac{(\epsilon_{t_{M+1}} - \epsilon_t) \wedge K}{K} \sum_{i = I(0, t(m), s(m))} \|x_{i+1} - x_i\|^2 \\
+ \frac{(\epsilon_{t_{M+1}} - \epsilon_t) \wedge K}{K} \sum_{i = I(0, t(m), s(m))} \|x_{i+1} - x_i\|^2 \right].
\]

(20)

Here, we used the definition \(t_1 = 0\).

By the way, from (4) and (5), we can also derive a different bound for \(\mathbb{E}[f(x_{t_{m+1}}) - f(x_{t_m})]\). For every \(q \in (0, 1/6)\), we have

\[
\mathbb{E}[f(x_{t_{m+1}}) - f(x_{t_m})] \\
= \mathbb{E}[f(x_{t_{m+1}}) - f(x_{t_m})|H_1] \mathbb{P}(H_1) \\
+ \mathbb{E}[f(x_{t_{m+1}}) - f(x_{t_m})|H_0] \mathbb{P}(H_0) \\
\leq (1 - 3q) \frac{1}{8\eta} \mathbb{E} \left[ \sum_{i = t_m}^{t_m+1-1} \|x_{i+1} - x_i\|^2 \right] \mathbb{P}(H_1) \\
+ \frac{c_\eta}{\eta} \left[ \frac{(t_{m+1} - t_m) \wedge K}{K} \sum_{i = I(0, t(m), s(m))} \|x_{i+1} - x_i\|^2 \\
+ \frac{(t_{m+1} - t_m) \wedge K}{K} \sum_{i = I(0, t(m), s(m))} \|x_{i+1} - x_i\|^2 \right] \mathbb{P}(H_1) \\
+ 3q \times 36\eta K^2T^2S(G + r^2).
\]
Observe that
\[
- \sum_{i=m+1}^{t_m+1} \frac{\eta}{\sqrt{m}} \left( \sum_{i=m}^{t_m} \Vert x_{i+1} - x_i \Vert^2 \right) + \sum_{i=m}^{t_m} \left( \sum_{i=m}^{t_m} \Vert x_{i+1} - x_i \Vert^2 \right) \cdot \mathbb{P}(H_t) \\
= - \sum_{i=m+1}^{t_m+1} \frac{\eta}{\sqrt{m}} \left( \sum_{i=m}^{t_m} \Vert x_{i+1} - x_i \Vert^2 \right) + \sum_{i=m}^{t_m} \left( \sum_{i=m}^{t_m} \Vert x_{i+1} - x_i \Vert^2 \right) \cdot \mathbb{P}(H_t) \\
\leq - \sum_{i=m+1}^{t_m+1} \frac{\eta}{\sqrt{m}} \left( \sum_{i=m}^{t_m} \Vert x_{i+1} - x_i \Vert^2 \right) + 3q \times 192\eta^2 (KTG^2 + r^2)
\]

Here, for the inequality, we used
\[
\Vert x_{i+1} - x_i \Vert^2 \leq 3\eta^2 \Vert v_{i+1} - \nabla f(x_i) \Vert^2 + 3\eta^2 \Vert \nabla f(x_i) \Vert^2 + 3\eta^2 r^2 \\
\leq 96\eta^2 KT G^2 + 3\eta^2 G^2 + 3\eta^2 r^2 \\
\leq 192\eta^2 (KTG^2 + r^2)
\]

Hence, with \( q := \eta^2 / \{96K^2 T^2 S(G + \eta^2) + 72\eta(KTG^2 + r^2)(c_J/(\eta \sqrt{v})) \} \) we get
\[
\mathbb{E}[f(x_{t_m+1} + f(x_{t_m})] \\
\leq - \frac{1}{16\eta} \mathbb{E} \left[ \sum_{i=m}^{t_m+1} \Vert x_{i+1} - x_i \Vert^2 \right] + 2\eta^2 \mathbb{E}[t_{m+1} - t_m] \\
+ \frac{c_J}{\eta} \mathbb{E} \left[ \frac{(t_{m+1} - t_m) \land K}{K} \sum_{i=I(0,t_{m},s_{(m)})}^{t_m-1} \Vert x_{i+1} - x_i \Vert^2 \\
+ \frac{(t_{m+1} - t_m) \land KT}{KT} \sum_{i=I(0,t_{m},s_{(m)})}^{t_{m-1}} \Vert x_{i+1} - x_i \Vert^2 \right] \\
+ \frac{(t_{m+1} - t_m) \land KT}{KT} \sum_{i=I(0,t_{m},s_{(m)})}^{t_{m-1}} \Vert x_{i+1} - x_i \Vert^2 ]
\]

Summing this inequality from \( m = 1 \) to \( M - 1 \) gives
\[
\mathbb{E}[f(x_{t_M}) - f(x_0)] \\
\leq - \frac{1}{16\eta} \sum_{m=1}^{M-1} \mathbb{E} \left[ \sum_{i=m}^{t_m+1} \Vert x_{i+1} - x_i \Vert^2 \right] + 3\eta^2 \mathbb{E}[t_{M}] \\
+ \frac{c_J}{\eta} \mathbb{E} \left[ \sum_{m=1}^{M-1} \left( \frac{(t_{m+1} - t_m) \land K}{K} \sum_{i=I(0,t_{m},s_{(m)})}^{t_m-1} \Vert x_{i+1} - x_i \Vert^2 \\
+ \frac{(t_{m+1} - t_m) \land KT}{KT} \sum_{i=I(0,t_{m},s_{(m)})}^{t_{m-1}} \Vert x_{i+1} - x_i \Vert^2 \right] \\
\right]
\]

48
Combining this inequality with (20), with we obtain

\[
\mathbb{E}[f(x_{i_M}) - f(x_0)] \\
\leq -\frac{1}{2} \left( e_{\mathcal{R}_1}^2 \eta - 3\eta c_r^2 \right) \mathbb{E}[\ell_M] \varepsilon^2 + \frac{1}{2} \left( e_{\mathcal{R}_1}^2 \eta + 3\eta c_r^2 \right) \sum_{m=1}^{M-1} \mathbb{P}(\mathcal{R}_m) \varepsilon^2 \\
- \frac{1}{16\eta} \mathbb{E} \left[ \sum_{i=0}^{t_{m-1}} \|x_{i+1} - x_i\|^2 \right] \\
+ \frac{2c \eta E_i}{\eta} \left[ \sum_{m=1}^{M-1} \left( \frac{t_{m+1} - t_m}{K} \right) \sum_{i=I(0,t(\ell_m),s(\ell_m))}^{i_m-1} \|x_{i+1} - x_i\|^2 \right] \\
+ \left( t_{m+1} - t_m \right) \frac{KT}{K} I(0,t(\ell_m),s(\ell_m))^{-1} \sum_{i=I(0,0,s(\ell_m))}^{i_m} \|x_{i+1} - x_i\|^2.
\]

We want to show that

\[
\sum_{i=0}^{t_{m-1}} \|x_{i+1} - x_i\|^2 \\
\geq \frac{1}{4} \sum_{m=1}^{M-1} \left( \frac{t_{m+1} - t_m}{K} \right) \sum_{i=I(0,t(\ell_m),s(\ell_m))}^{i_m-1} \|x_{i+1} - x_i\|^2 \\
+ \left( t_{m+1} - t_m \right) \frac{KT}{K} I(0,t(\ell_m),s(\ell_m))^{-1} \sum_{i=I(0,0,s(\ell_m))}^{i_m} \|x_{i+1} - x_i\|^2.
\]

To prove this inequality, we fix \(i' \in [t_{M-1}] \cup \{0\}\) and show that the coefficient of \(\|x_{i'+1} - x_{i'}\|^2\) of the left hand side is greater than or equal to the one of the right hand side. At first, the coefficient of \(\|x_{i'+1} - x_{i'}\|^2\) of the left hand side is trivially \(1\). Next we consider the right hand side. Let \(s'\) be the natural number that satisfies \(I(0,0,s') \leq i' < I(0,0,s' + 1)\). Also, \(i'\) be the natural number that satisfies \(I(0,t',s') \leq i' < I(0,t' + 1, s')\). We define \(m_1 := \{m \in \mathbb{N} | I(0,t',s') \leq i_m < I(0,t' + 1, s')\}\) and \(m_2 := \{m \in \mathbb{N} | I(0,0,s') \leq i_m < I(0,0,s' + 1)\}\). We can see that the coefficient of \(\|x_{i'+1} - x_{i'}\|^2\) in the right hand side is

\[
\leq \frac{1}{4} \left( 1 + \sum_{m \in m_1 \setminus \{\max\{m_1\}\}} \frac{t_{m+1} - t_m}{K} + 1 + \sum_{m \in m_2 \setminus \{\max\{m_2\}\}} \frac{t_{m+1} - t_m}{K} \right) \\
\leq 1.
\]

Here, for the first inequality we used the facts that (i) \(I(0,t(\ell_m),s(\ell_m)) \leq i' \leq i_m - 1\) implies \(m \in m_1\) and (ii) \(I(0,0,s(\ell_m)) \leq i' \leq I(0,t(\ell_m),s(\ell_m)) - 1\) implies \(m \in m_2\). To show (i), note that \(i_m < I(0,t',s')\) implies \(i_m - 1 < i'\) and \(i_m \geq I(0,t' + 1, s')\) implies \(I(0,t(\ell_m),s(\ell_m)) \geq I(0,t' + 1, s') > i'\). Similarly, to show (ii), observe that \(i_m < I(0,0,s')\) implies \(i' > i_m > I(0,t(\ell_m),s(\ell_m)) - 1\) and \(i_m \geq I(0,0,s' + 1)\) implies \(i' < I(0,0,s' + 1) \leq I(0,0,s(\ell_m))\). For the last inequality we used \(\sum_{m \in m_1 \setminus \{\max\{m_1\}\}} \frac{t_{m+1} - t_m}{K} \leq K\) and \(\sum_{m \in m_2 \setminus \{\max\{m_2\}\}} \frac{t_{m+1} - t_m}{K} \leq K\).
We choose $c_\eta \leq 1/128$. Then, we obtain
\[
    f(x_*) - f(\bar{x}) \leq \mathbb{E}[f(x_{i_M}) - f(x_0)] + \eta r^2 \\
    \leq \left( \frac{c_x c_\eta^2 \eta}{32} - 3c_\eta^2 \eta \right) \mathbb{E}[, M] \epsilon^2 + \left( \frac{c_x c_\eta^2 \eta}{32} + 3c_\eta^2 \eta \right) \sum_{m=1}^{M-1} \mathbb{P}(x_m \in \mathcal{R}_{\eta}) \epsilon^2.
\]
Here, for the first inequality, we used $\mathbb{E}[f(x_{i_M})] \geq f(x_*)$ and $\mathbb{E}[f(x_0)] \leq f(\bar{x}) + (\nabla f(\bar{x}), x_0 - \bar{x}) = f(\bar{x}) + \eta^2 \mathcal{L}^2 / 2 \leq f(\bar{x}) + \eta r^2$ by the smoothness of $f$. For the second inequality, we used the above bounds with the definition of $c_\eta$ for $\mathbb{E}[f(x_{i_M}) - f(x_0)]$. This finishes the proof.

**Proof of Theorem 4.4**

Now, we choose $S \geq 48(f(x_0) - f(x_*)/(c_x^2 \eta KT \epsilon^2) = \tilde{O}((f(x_0) - f(x_*)/(\eta KT \epsilon^2))$. Note that $\mathbb{E}[\epsilon] \geq KT S/8 \geq 6(f(x_0) - f(x_*)/(c_x^2 \eta \epsilon^2)$.

Suppose that $\mathbb{P}(x_{i_M} \in \mathcal{R}_\eta) \leq 3/4$ for every $m \in [M - 1]$. Then, since $c_x c_\eta^2 \eta/32 - 3c_\eta^2 \eta - (3/4) \times (c_x c_\eta^2 \eta/32 + 3c_\eta^2 \eta) \geq 1/4(c_x c_\eta^2 \eta/32 - 21)c_x^2 \eta \geq c_x^2 \eta/4$ under $c_x \geq 32 \times 22$, we have
\[
    f(x_*) - f(x_0) \leq -\frac{c_x^2 \eta}{4} \mathbb{E}[\epsilon] \epsilon^2
\]
and thus
\[
    \mathbb{E}[\epsilon] \leq \frac{4(f(x_0) - f(x_*)}{c_x^2 \eta \epsilon^2}
\]
from Proposition B.5. This contradicts the previous lower bound of $\mathbb{E}[\epsilon]$. Therefore, we conclude that there exists $m \in [M - 1]$ such that $\mathbb{P}(x_{i_M} \in \mathcal{R}_\eta) > 3/4$. Remember that $E_i$ is the event that $x_{i'} \notin \mathcal{R}_\eta$ for all $i' \leq i$. This implies $\mathbb{P}(E_i \cap E_{i-1} \{|M-1| \geq KT S/8}$ Thus, from Markov’s inequality, it holds that $\mathbb{P}(\epsilon \geq KT S) \leq 1/8$.

This yields
\[
    \mathbb{P}(E_{KT S}) = \mathbb{P}(E_{KT S}|E_{i_M-1} \geq KT S) \mathbb{P}(E_{i_M-1} \geq KT S) + \mathbb{P}(E_{KT S}|E_{i_M-1} < KT S) \mathbb{P}(E_{i_M-1} < KT S)
    \leq 1 \times \frac{1}{4} + \mathbb{P}(E_{i_M-1}) \leq 1/2.
\]

This finishes the proof. 

---
