Abstract

The aim of this paper is to give a formulation of the dynamics of nonlinear RLC circuits as a geometric Birkhoffian system and to discuss in this context the concepts of regularity, conservativeness, dissipativeness. An RLC circuit, with no assumptions placed on its topology, will be described by a family of Birkhoffian systems, parameterized by a finite number of real constants which correspond to initial values of certain state variables of the circuit. The configuration space and a special Pfaffian form, called Birkhoffian, are obtained from the constitutive relations of the resistors, inductors and capacitors involved and from Kirchhoff's laws. Under certain assumptions on the voltage-current characteristic for resistors, it is shown that a Birkhoffian system associated to an RLC circuit is dissipative. For RLC networks which contain a number of pure capacitor loops or pure resistor loops the Birkhoffian associated is never regular. A procedure to reduce the original configuration space to a lower dimensional one, thereby regularizing the Birkhoffian, it is also presented. In order to illustrate the results, specific examples are discussed in detail.

Keywords: geometric methods in differential equations, Birkhoffian differential systems, Birkhoffian vector fields, dissipative dynamical systems, electrical networks

1 Introduction

Lagrangian and Hamiltonian mechanics continue to attract a large amount of attention in the literature, because many mechanical and electro-mechanical systems may be modelled within these frameworks. During the past ten years, a far-reaching generalization of the Hamiltonian framework has been developed in a series of papers. This generalization, which is based on the geometric notion of generalized Dirac structure, gives rise to implicit Hamiltonian systems (see for example papers by Maschke and van der Schaft [10], van der Schaft [12]). In the papers by Yoshimura and Marsden [15] the concept of Dirac structures and variational principle are used to define and develop the basic properties of implicit Lagrangian systems.
An alternative approach to the study of dynamical systems which appears to cover a wide class of systems, among them the nonholonomic systems, the degenerate systems and the dissipative ones, is the Birkhoffian formalism, a global formalism of the dynamics of implicit systems of second order ordinary differential equations on a manifold. The classical book by G. D. Birkhoff [2], contains in Chapter I many interesting ideas about classical dynamics from the viewpoint of differential geometry. In order to present these ideas in a coordinate free fashion, one considers the formalism of 2-jets (see for example Kobayashi and Oliva [7]). The space of configurations is a smooth $m$-dimensional differentiable connected manifold and the covariant character of the Birkhoff generalized forces is obtained by introducing the notion of elementary work, called Birkhoffian, a special Pfaffian form defined on the 2-jets manifold. The dynamical system associated to this Pfaffian form is a subset of the 2-jets manifold which defines an implicit second order ordinary differential system. The notion of Birkhoffian allows to formulate the concepts of reciprocity, regularity, affine structure in the accelerations, conservativeness, in an intrinsic way.

The electrical circuits theory benefits from many tools developed in mathematics. In order to study the dynamics of LC and RLC electrical circuits, various Lagrangian and Hamiltonian formulations have been considered in the literature (see for example [3], [4], [9], [10], [12], [13], and the references therein). To describe LC circuit equations, Hamiltonian formulations have been used more often. In [9], the dynamics of a nonlinear LC circuit is shown to be of Hamiltonian nature with respect to a certain Poisson bracket which may be degenerate, that is, non-symplectic. The dynamics of "complete" RLC networks was described by Brayton and Moser [4] in terms of a function of inductor currents and capacitor voltages, called the mixed potential function. However, for all those formulations, a certain topological assumption on the electrical circuit appears to be crucial, that is, the circuit is supposed to contain neither loops of capacitors nor cutsets of inductors. In [10], [12] and [3] the Poisson bracket is replaced by the more general notion of a Dirac structure on a vector space, leading to implicit Hamiltonian systems. In this formalism, it is possible to include LC networks which do not obey the topological assumption mentioned before. In [15] an example of LC circuit in the context of implicit Lagrangian systems is given for a degenerate Lagrangian system with holonomic constraints.

The potential relevance of the Birkhoffian formalism in the context of electrical circuits is discussed by Ionescu and Scheurle [8], where a formulation of general nonlinear LC circuits within the framework of Birkhoffian dynamical systems on manifolds is presented. In [8] specific examples of electrical networks are discussed in this framework. These are networks which contain closed loops formed by capacitors, as well as inductor cutsets, and also LC networks which contain independent voltage sources as well as independent current sources.

In the paper at hand we present a formulation of the dynamics of nonlinear RLC electrical circuits within the framework of Birkhoffian systems. Based on Kirchhoff’s laws and the constitutive relations for the resistors, inductors, capacitors involved, we get for a nonlinear RLC circuit, a whole family of configuration spaces and a special Pfaffian forms, called Birkhoffians. The configurations
spaces are parameterized by a finite number of real constants which correspond to initial values of certain state variables of the circuit. In particular, we can allow pure capacitor loops as well as pure inductor cutsets. Under certain assumptions on the voltage-current characteristic for resistors, it is shown that a Birkhoffian system associated to an RLC circuit is dissipative.

The paper is organized as follows. In Section 2, we recall the basics of Birkhoffian systems (see [2]) presented from the viewpoint of differential geometry using the formalism of jets (see [7]). In particular, we introduce the notion of dissipative Birkhoffian system, in order to be able to treat the case of RLC networks in the next section. In Section 3, our Birkhoffian formulation of the dynamic equations of a nonlinear RLC circuit is given. Properties of the corresponding Birkhoffian such as its regularity and its dissipativenss are also discussed in this section. For electrical RLC networks which contain a number of only capacitor loops or only resistors loops, we present a systematic procedure to reduce the original configuration space to a lower dimensional one, thereby regularizing the Birkhoffian. On the reduced configuration space the reduced Birkhoffian will still be dissipative. Finally, in section 4 we consider two specific examples. These examples are supposed to serve our purpose of demonstrating the power of the Birkhoffian approach.

**Acknowledgement.** I would like to express my gratitude to Professor Marsden for valuable discussions concerning the topic of this paper.

## 2 Birkhoffian systems

For a smooth m-dimensional differentiable connected manifold $M$, we consider the tangent bundles $(TM, \pi_M, M)$ and $(TTM, \pi_{TM}, TM)$. Let $q = (q^1, q^2, ..., q^m)$ be a local coordinate system on $M$. This induces natural local coordinate systems on $TM$ and $TTM$, denoted by $(q, \dot{q})$, respectively $(q, \dot{q}, dq, d\dot{q})$. The 2-jets manifold $J^2(M)$ is a $3m$-dimensional submanifold of $TTM$ defined by

$$J^2(M) = \{z \in TTM \mid T\pi_M(z) = \pi_{TM}(z)\} \quad (2.1)$$

where $T\pi_M : TTM \to TM$ is the tangent map of $\pi_M$. We write $\pi_J := \pi_{TM}|_{J^2(M)} = T\pi_M|_{J^2(M)}$. $(J^2(M), \pi_J, TM)$, called the 2-jet bundle (see [4]), is an affine bundle modelled on the vertical vector bundle $(V(M), \pi_{TM}|_{V(M)}, TM)$, $V(M) = \bigcup_{v \in TM} V_v(M)$, where $V_v(M) = \{z \in T_vTM \mid (T\pi_M)_v(z) = 0\}$. In [1], [11] this bundle is denoted by $T^2(M)$ and named second-order tangent bundle.

In natural local coordinates, the equality in (2.1) yields $(q, \dot{q}, dq, d\dot{q}|_{J^2(M)})$ as a local coordinate system on $J^2(M)$. We set $\dot{q} := d\dot{q}|_{J^2(M)}$. Thus, a local coordinate system $q$ on $M$ induces the natural local coordinate system $(q, \dot{q}, \dot{q})$ on $J^2(M)$. For further details on this affine bundle see [1], [2], [11].

A Birkhoffian corresponding to the configuration manifold $M$ is a smooth 1-form $\omega$ on $J^2(M)$ such that, for any $x \in M$, we have

$$i_x^*\omega = 0 \quad (2.2)$$
where \( i_x : \beta^{-1}(x) \to J^2(M) \) is the embedding of the submanifold \( \beta^{-1}(x) \) into \( J^2(M) \), \( \beta = \pi_M \circ \pi_J \). From this definition it follows that, in the natural local coordinate system \((q, \dot{q}, \ddot{q})\) of \( J^2(M) \), a Birkhoffian \( \omega \) is given by

\[
\omega = \sum_{j=1}^{m} Q_j(q, \dot{q}, \ddot{q}) dq^j
\]  

(2.3)

with certain functions \( Q_j : J^2(M) \to \mathbb{R} \).

The pair \((M, \omega)\) is said to be a Birkhoff system (see [7]).

The differential system associated to a Birkhoffian \( \omega \) (see [7]) is the set (maybe empty) \( D(\omega) \), given by

\[
D(\omega) := \{ z \in J^2(M) \mid \omega(z) = 0 \}
\]  

(2.4)

The manifold \( M \) is the space of configurations of \( D(\omega) \), and \( D(\omega) \) is said to have \( m \) 'degrees of freedom'. The \( Q_i \) are the 'generalized external forces' associated to the local coordinate system \((q)\). In the natural local coordinate system, \( D(\omega) \) is characterized by the following implicit system of second order ODE's

\[
Q_j(q, \dot{q}, \ddot{q}) = 0 \text{ for all } j = 1, m
\]  

(2.5)

We conclude that the Birkhoffian formalism is a global formalism for the dynamics of implicit systems of second order differential equations on a manifold.

Let us now associate a vector field to a Birkhoffian \( \omega \).

A vector field \( Y \) on the manifold \( TM \) is a smooth function \( Y : TM \to TT M \) such that \( \pi_T M \circ Y = \text{id} \). Any vector field \( Y \) on \( TM \) is called second order vector field on \( TM \) if and only if \( T\pi_T M(Y_v) = v \) for all \( v \in TM \).

A cross section \( X \) of the affine bundle \((J^2(M), \pi_J, TM)\), that is, a smooth function \( X : TM \to J^2(M) \) such that \( \pi_J \circ X = \text{id} \), can be identified with a special vector field on \( TM \), namely, the second order vector field on \( TM \) associated to \( X \). Indeed, because \((J^2(M), \pi_J, TM)\) is a sub-bundle of \((TT M, \pi_T M, TM)\) as well as of \((TT M, T\pi_T M, TM)\), its sections can be regarded as sections of these two tangent bundles. Thus, using the canonical embedding \( i : J^2(M) \to TT M \), \( X \) can be identified with \( Y \), that is, \( Y = i \circ X \).

In natural local coordinates, a second order vector field can be represented as

\[
Y = \sum_{j=1}^{m} \left[ \dot{q}^j \frac{\partial}{\partial q^j} + \ddot{q}^j(q, \dot{q}) \frac{\partial}{\partial \dot{q}^j} \right]
\]  

(2.6)

A Birkhoffian vector field associated to a Birkhoffian \( \omega \) of \( M \) (see [7]) is a smooth second order vector field on \( TM \), \( Y = i \circ X \), with \( X : TM \to J^2(M) \), such that \( \text{Im}X \subset D(\omega) \), that is

\[
X^\ast \omega = 0
\]  

(2.7)

In the natural local coordinate system, a Birkhoffian vector field is given by the expression (2.6), such that \( Q_j(q, \dot{q}, \ddot{q}(q, \dot{q})) = 0 \).
A Birkhoffian $\omega$ is **regular** if and only if

$$\det \left[ \frac{\partial Q_j}{\partial \ddot{q}_i}(q, \dot{q}, \ddot{q}) \right]_{i,j=1,...,m} \neq 0 \quad (2.8)$$

for all $(q, \dot{q}, \ddot{q})$, and for each $(q, \dot{q})$, there exists $\ddot{q}$ such that $Q_j(q, \dot{q}, \ddot{q}) = 0$, $j = 1, ..., m$.

If a Birkhoffian $\omega$ of $M$ is regular, then it satisfies the principle of determinism, that is, there exists an unique Birkhoffian vector field $Y = i \circ X$ associated to $\omega$ such that $\text{Im} \ X = D(\omega)$ (see [7]).

A Birkhoffian $\omega$ of the configuration space $M$ is called **conservative** if and only if there exists a smooth function $E_\omega : TM \rightarrow \mathbb{R}$ such that

$$(X^*\omega)Y = dE_\omega(Y) \quad (2.9)$$

for all second order vector fields $Y = i \circ X$ (see [7]).

Equation (2.9) is equivalent, in the natural local coordinate system, to the identity (see [2], p. 16, eq. 4)

$$\sum_{j=1}^{m} Q_j(q \dot{q}, \ddot{q}) \ddot{q}_j = \sum_{j=1}^{m} \left[ \frac{\partial E_\omega}{\partial \dot{q}_j} \dot{q}_j + \frac{\partial E_\omega}{\partial \ddot{q}_j} \ddot{q}_j \right] \quad (2.10)$$

$E_\omega$ is constant on $TM$ if and only if $dE_\omega(Y) = 0$ for all second order vector fields $Y$ on $TM$ (see [7]).

If $\omega$ is conservative and $Y$ is a Birkhoffian vector field, then (2.9) becomes

$$dE_\omega(Y) = 0 \quad (2.11)$$

This means that $E_\omega$ is constant along the trajectories of $Y$.

We now introduce the concept of a dissipative Birkhoffian. A **vertical 1-form on $TM$** (see for example [14]) is a 1-form $\Psi$ on $TM$ such that $\Psi(V^v) = 0$, for all $V$ vector field on $M$, where $V^v$ is the vertical lift of the vector field $V$ to $TM$. The local expression of a vertical 1-form is

$$\Psi = \sum_{j=1}^{m} \psi_j(q, \dot{q}) dq^j \quad (2.12)$$

A 1-form $D$ on $TM$ is called **dissipative** if and only if $D$ is vertical and $D(Y) > 0$, for all $Y$ second order vector field on $TM$. Allowing for (2.12), the local expression of $D$ is

$$D = \sum_{j=1}^{m} D_j(q, \dot{q}) dq^j \quad (2.13)$$

and from (2.12), (2.6), the inequality $D(Y) > 0$ becomes

$$\sum_{j=1}^{m} D_j(q, \dot{q}) \dot{q}_j > 0 \quad (2.14)$$
A Birkhoffian $\omega$ of the configuration space $M$ is called \textbf{dissipative} if and only if there exists a smooth function $E_{0,\omega} : TM \rightarrow \mathbb{R}$ such that
\[
(X^*\omega)Y = dE_{0,\omega}(Y) + D(Y)
\] (2.15)
for all second order vector fields $Y = i \circ X$ on $TM$, $D$ being a dissipative 1-form on $TM$.

Equation (2.15) is equivalent, in a local coordinate system, to the identity
\[
\sum_{j=1}^{m} Q_j(q, \dot{q}, \ddot{q})\dot{q}^j = \sum_{j=1}^{m} \left[ \frac{\partial E_{0,\omega}}{\partial \dot{q}^j} \dot{q}^j + \frac{\partial E_{0,\omega}}{\partial q^j} \ddot{q}^j + D_j(q, \dot{q}) \dot{q}^j \right]
\] (2.16)

In view of (2.14), we obtain from (2.15),
\[
(X^*\omega)Y > dE_{0,\omega}(Y)
\] (2.17)
for all second order vector field $Y = i \circ X$. That is equivalent, in local coordinates, to the dissipation inequality
\[
\sum_{j=1}^{m} Q_j(q, \dot{q}, \ddot{q})\dot{q}^j > \sum_{j=1}^{m} \left[ \frac{\partial E_{0,\omega}}{\partial \dot{q}^j} \dot{q}^j + \frac{\partial E_{0,\omega}}{\partial q^j} \ddot{q}^j \right].
\] (2.18)

If $\omega$ is a dissipative Birkhoffian and $Y$ is the Birkhoffian vector field, then (2.17) becomes
\[
dE_{0,\omega}(Y) < 0.
\] (2.19)

This means that $E_{0,\omega}$ is nonincreasing along the trajectories of $Y$.

If the dissipative 1-form on $TM$ has the particular expression
\[
D = \sum_{i,j=1}^{m} D_{ij}(q)\dot{q}^i dq^j
\] (2.20)
when we calculate the function $D(Y)$ on $TM$, we obtain the so called \textit{Rayleigh dissipation function} $\mathcal{R} : TM \rightarrow \mathbb{R}$
\[
\mathcal{R}(q, \dot{q}) = \sum_{i,j=1}^{m} D_{ij}(q)\dot{q}^i \dot{q}^j
\] (2.21)

\section{RLC circuit dynamics}

A simple electrical circuit provides us with an \textit{oriented connected} graph, that is, a collection of points, called nodes, and a set of connecting lines or arcs, called branches, such that in each branch is given a direction and there is at least one path between any two nodes. A path is a sequence of branches such that the origin of the next branch coincides with the end of the previous one. The graph will be assumed to be \textit{planar}, that is, it can be drawn in a plane without
branches crossing. For the graph theoretic terminology, see, for example [6].

Let \( b \) be the total number of branches in the graph, \( n \) be one less than the number of nodes and \( m \) be the cardinality of a selection of loops that cover the whole graph. Here, a loop is a path such that the first and last node coincide and that does not use the same branch more than once. By Euler’s polyhedron formula, \( b = m + n \).

We choose a reference node and a current direction in each \( l \)-branch of the graph, \( l = 1, \ldots, b \). We also consider a covering of the graph with \( m \) loops, and a current direction in each \( j \)-loop, \( j = 1, \ldots, m \). We assume that the associated graph has at least one loop, meaning that \( m > 0 \).

A graph can be described by matrices: a \((bn)\)-matrix \( B \in \mathcal{M}_{bn}(\mathbb{R}) \), rank\( (B) = n \), called incidence matrix and a \((bm)\)-matrix \( A \in \mathcal{M}_{bm}(\mathbb{R}) \), rank\( (A) = m \), called loop matrix. These matrices contain only 0, 1, -1. An element of the matrix \( B \) is 0 if a branch \( b \) is not incident with a node \( n \), 1 if branch \( b \) enters node \( n \) and -1 if branch \( b \) leaves node \( n \), respectively. An element of the matrix \( A \) is 0 if a branch \( b \) does not belong to a loop \( m \), 1 if branch \( b \) belongs to loop \( m \) and their directions agree and -1 if branch \( b \) belongs to loop \( m \) and their directions oppose, respectively. For the fundamentals of electrical circuit theory, see, for example [5].

The states of the circuit have two components, the currents through the branches, denoted by \( i \in \mathbb{R}^b \), and the voltages across the branches, denoted by \( v \in \mathbb{R}^b \).

Using the matrices \( A \) and \( B \), Kirchhoff’s current law and Kirchhoff’s voltage law can be expressed by the equations

\[
B^T i = 0 \quad (KCL) \tag{3.1}
\]

\[
A^T v = 0 \quad (KVL) \tag{3.2}
\]

Tellegen’s theorem establishes a relation between the matrices \( A^T \) and \( B^T \): the kernel of the matrix \( B^T \) is orthogonal to the kernel of the matrix \( A^T \) (see e.g., [4] page 5).

The next step is to introduce the branch elements in a simple electrical circuit. The branches of the graph associated to a RLC electrical circuit, can be classified into three categories: resistive branches, inductor branches, and capacitor branches. Let \( r \) denote the number of resistive branches, \( k \) the number of inductor branches and \( p \) the number of capacitor branches, respectively. We assume that just one electrical device is associated to each branch, then, we have \( b = r + k + p \).

Thus, we can write \( i = (i_\Gamma, i_a, i_\alpha) \in \mathbb{R}^r \times \mathbb{R}^k \times \mathbb{R}^p \cong \mathbb{R}^b \), where \( i_\Gamma, i_a, i_\alpha \) are the currents through the resistors, the inductors, the capacitors, respectively, and \( v = (v_\Gamma, v_a, v_\alpha) \in \mathbb{R}^r \times \mathbb{R}^k \times \mathbb{R}^p \cong \mathbb{R}^b \), where \( v_\Gamma, v_a, v_\alpha \) describe the voltage drops across the resistors, the inductors, the capacitors, respectively.

Each capacitor is supposed to be charge-controlled. For the nonlinear capacitors we assume

\[
v_\alpha = C_\alpha(q_\alpha), \quad \alpha = 1, \ldots, p \tag{3.3}
\]

where the functions \( C_\alpha : \mathbb{R} \rightarrow \mathbb{R}\setminus\{0\} \) are smooth and invertible, and the \( q_\alpha \)’s denote the charges of the capacitors. The current through a capacitor is given
by the time-derivative of the corresponding charge

\[ t_\alpha = \frac{dQ_\alpha}{dt}, \quad \alpha = 1, ..., p \]  

(3.4)

t being the time variable.

Each inductor is supposed to be current-controlled. For the nonlinear inductors we assume

\[ v_a = L_a(t_a) \frac{dI_a}{dt}, \quad a = 1, ..., k \]  

(3.5)

where \( L_a : \mathbb{R} \rightarrow \mathbb{R} \setminus \{0\} \) are smooth invertible functions.

There are several types of nonlinear resistors, among them current controlled resistors and voltage controlled resistors. Generally, their constitutive relations are defined by some continuous functions of \( \Gamma \) and \( v_\Gamma \), that is, \( f_\Gamma (I_\Gamma, v_\Gamma) = 0, \Gamma = 1, ..., r \).

### 3.1 Current controlled resistors

We first consider the case that the nonlinear resistors are current controlled, that is, the constitutive relations are given by

\[ v_\Gamma = R_\Gamma(I_\Gamma), \quad \Gamma = 1, ..., r \]  

(3.6)

where \( R_\Gamma : \mathbb{R} \rightarrow \mathbb{R} \) are smooth functions. In order to obtain a dissipative Birkhoffian, we assume that, for all \( x \neq 0 \),

\[ R_\Gamma(x) > 0, \quad \forall \Gamma = 1, ..., r \]  

(3.7)

that is, for each nonlinear resistor, the graph of the function \( R_\Gamma \) lies in the union of the first and the third quadrant.

For linear resistors the relations (3.6) can be written in the form

\[ v_\Gamma = R_\Gamma I_\Gamma \]  

(3.8)

where \( R_\Gamma > 0 \) are real constants.

Taking into account (3.3), (3.4), (3.5), (3.6), the equations (3.1), (3.2) become

\[
\begin{align*}
B^T \begin{pmatrix} I_\Gamma \\ I_a \\ \frac{dQ_\alpha}{dt} \end{pmatrix} &= 0 \\
A^T \begin{pmatrix} R_\Gamma(I_\Gamma) \\ L_a(t_a) \frac{dI_a}{dt} \\ C_\alpha(Q_\alpha) \end{pmatrix} &= 0
\end{align*}
\]  

(3.9)

In the following we give a Birkhoffian formulation for the network described by the system of equations (3.7), using the same procedure as in [8]. That is, using the first set of equations (3.8), we are going to define a family of m-dimensional.
affine-linear configuration spaces \( M_c \subset \mathbb{R}^b \) parameterized by a constant vector \( c \) in \( \mathbb{R}^n \). This vector is related to the initial values of the \( q \)-variables at some instant of time. A Birkhoffian \( \omega_c \) on the configuration space \( M_c \) arises from a linear combination of the second set of equations (3.9). Thus, \( (M_c, \omega_c) \) will be a family of Birkhoff systems that describe the considered RLC network.

We notice that the first set of equations (3.9) remains exactly the same for linear and nonlinear electrical devices. Thus, for obtaining the configuration space, it is not important whether the devices are linear or nonlinear.

Let \( H : \mathbb{R}^b \rightarrow \mathbb{R}^n \) be the linear map that, with respect to a coordinate system \((x_1, ..., x_b)\) on \( \mathbb{R}^b \), is given by

\[
H(x_1, ..., x_b) = B^T \begin{pmatrix} x_1 \\ \vdots \\ x_b \end{pmatrix}
\]

(3.10)

Then, \( H^{-1}(c) \), with \( c \) a constant vector in \( \mathbb{R}^n \), is an affine-linear subspace in \( \mathbb{R}^b \). Its dimension is \( m = b - n \), because \( \text{rank}(B) = n \).

We define \( M_c \) as

\[
M_c := H^{-1}(c)
\]

(3.11)

We denote local coordinates on \( M_c \) by \( q = (q^1, ..., q^m) \). Then, the natural coordinate system on the 2-jets bundle \( J^2(M_c) \) is given by \( (q, \dot{q}, \ddot{q}) \).

We will now represent the Birkhoffian in a specific coordinate system on \( M_c \):

In the vector spaces \( \mathbb{R}^r, \mathbb{R}^k \), we identify points and vectors

\[
i_{\Gamma} := \frac{dQ_{[\Gamma]}}{dt}, \quad i_a := \frac{dQ_{(a)}}{dt}
\]

(3.12)

with \((Q_{[\Gamma]})_{\Gamma=1,...,r}, (Q_{(a)})_{a=1,...,k}\) coordinate systems on \( \mathbb{R}^r \), respectively, on \( \mathbb{R}^k \).

Taking into account (3.12) and the fact that the matrix \( B^T \) is a constant matrix, we integrate the first set of equations (3.9) to arrive at

\[
B^T \begin{pmatrix} Q_{[\Gamma]} \\ Q_{(a)} \\ Q_{\alpha} \end{pmatrix} = c
\]

(3.13)

with \( c \) a constant vector in \( \mathbb{R}^n \).

Likewise consider coordinates in \( \mathbb{R}^b \cong \mathbb{R}^r \times \mathbb{R}^k \times \mathbb{R}^p \)

\[
x^1 := Q_{[1]}, ..., x^r := Q_{[r]}, x^{r+1} := Q_{(1)}, ..., x^{r+k} := Q_{(k)}, \quad x^{r+k+1} := Q_1, ..., x^b := Q_p
\]

(3.14)

From (3.11), (3.13), we see that we can define coordinates on \( M_c \) by solving the equations (3.11) in terms of an appropriate set of \( m \) of the \( Q \)-variables, say \( q = (q^1, ..., q^m) \). In other words, we express any of the \( x \)-variables as a function of \( q = (q^1, ..., q^m) \), namely,

\[
x^\Gamma = \sum_{j=1}^m N^\Gamma_j q^j + \text{const}, \quad \Gamma = 1, ..., r
\]
\[ x^\alpha = \sum_{j=1}^{m} N^\alpha_j q^j + \text{const}, \quad \alpha = r + 1, \ldots, r + k \]

\[ x^\alpha = \sum_{j=1}^{m} N^\alpha_j q^j + \text{const}, \quad \alpha = r + k + 1, \ldots, b \]  

(3.15)

with certain constants \( N^T_j, N^a_j, N^\alpha_j \). Here we can think of the constants \( \text{const} \) as being initial values of the \( x \)-variables at some instant of time.

From (3.4), (3.12), (3.14) and differentiating (3.15) we get

\[ i = N \dot{q} \]

(3.16)

with the matrix of constants \( N \in \mathbb{M}_{bm}(\mathbb{R}) \), for some \( \dot{q} \in \mathbb{R}^m \).

Using Tellegen’s theorem and a fundamental theorem of linear algebra, we now find a relation between the matrices \( N \) and \( A \).

By a fundamental theorem of linear algebra we have

\[ (\text{Ker}(A^T))^\perp = \text{Im}(A) \]

(3.17)

where \( A \in \mathbb{M}_{bm}(\mathbb{R}) \), \( \text{Ker}(A^T) := \{ x \in \mathbb{R}^b \mid A^T x = 0 \} \) is the kernel of \( A^T \), \( \text{Im}(A) := \{ x \in \mathbb{R}^b \mid Ay = x, \text{ for some } y \in \mathbb{R}^m \} \) is the image of \( A \) and \( ^\perp \) denotes the orthogonal complement in \( \mathbb{R}^b \) of the respective vector subspace.

For the incidence matrix \( B \in \mathbb{M}_{bn}(\mathbb{R}) \) and the loop matrix \( A \in \mathbb{M}_{bm}(\mathbb{R}) \), which satisfy Kirchoff’s law (3.1), (3.2), Tellegen’s theorem writes as

\[ \text{Ker}(B^T) = (\text{Ker}(A^T))^\perp \]

(3.18)

From the first set of equations in (3.4), and by construction of the matrix \( N \) in (3.16), we have

\[ \text{Ker}(B^T) = \text{Im}(N) \]

(3.19)

Therefore, using (3.17), (3.18), (3.19), we obtain \( \text{Im}(A) = \text{Im}(N) \). Then, another application of (3.17) yields

\[ \text{Ker}(A^T) = \text{Ker}(N^T) \]

(3.20)

Taking into account (3.20), we see that there exists a nonsingular matrix \( \mathcal{C} \in \mathbb{M}_{mn}(\mathbb{R}) \) satisfying

\[ \mathcal{C} A^T = N^T \]

(3.21)

The matrix \( \mathcal{C} \) provides a relation between the vector of the \( m \) independent loop currents and the coordinate vector \( q \) introduced on \( M_c \).

Taking into account (3.21), we define the Birkhoffian \( \omega_c \) of \( M_c \) such that the differential system (3.5) is the linear combination of the second set of equations in (3.9) obtained by replacing \( A^T \) with the matrix \( N^T \). Thus, in terms of \( q \)-coordinates as chosen before, the expressions of the components \( Q_j(q, \dot{q}, \ddot{q}) \) are

\[ Q_j(q, \dot{q}, \ddot{q}) = F_j(q)\ddot{q} + H_j(q) + G_j(q), \quad j = 1, \ldots, m \]  

(3.22)
Let us now discuss the regularity of the Birkhoffian given by (3.22).

or only resistors, or only resistors and capacitors, then the Birkhoffian (3.22) never regular associated to the network is given by (3.7), nonlinear inductors and capacitors described by (3.5), respectively (3.3), dissipative Birkhoffian where

According to (3.29), the Birkhoffian (3.22) satisfies (2.16) with the function $E_0(q)$ given by (3.28) and the dissipative 1-form $D$ given by (3.24), since $\frac{\partial^2 E_0}{\partial q^i \partial q^j} \neq \frac{\partial^2 E_0}{\partial q^j \partial q^i}$.

We note that the Birkhoffian (3.22) is not conservative. We easily see that there does not exist a function $E_0$ such that (2.10) is fulfilled for the Birkhoffian (3.22), since $\frac{\partial^2 E_0}{\partial q^i \partial q^j} \neq \frac{\partial^2 E_0}{\partial q^j \partial q^i}$.

For an RLC electrical network with nonlinear resistors, described by (3.6), nonlinear inductors and capacitors described by (3.8), respectively (3.9), we claim that the Birkhoffian (3.22) is a dissipative Birkhoffian.

Indeed, in the view of the assumption (3.7), the vertical 1-form $D$ on $TM$ given by

$$D = \sum_{j=1}^{m} H_j(\dot{q}) dq^j$$

with $H_j(\dot{q})$ in (3.24), is dissipative, that is,

$$\sum_{j=1}^{m} H_j(\dot{q}) \dot{q}^j = r \sum_{\Gamma=1}^{r} \text{Re} \left( \sum_{j=1}^{m} N_j^{\Gamma} \dot{q}^j \right) \left( \sum_{j=1}^{m} N_j^{\Gamma} \dot{q}^j \right) > 0$$

We showed in [8] that the following smooth function $E_0(q)$ on $TM$

$$E_0 = \sum_{a=r+1}^{r+k} \sum_{a'=1}^{m} \sum_{i_1 < \ldots < i_{l-1} = 1}^{m} (-1)^{l+1} \int_{l} \left[ \tilde{I}_{a'-r}^{(l-1)}(\dot{q})N_{i_1}^{a} \ldots N_{i_{l-1}}^{a} dq^1 \ldots dq^l \right]$$

$satisfies the identity

$$\sum_{j=1}^{m} [F_j(\dot{q}) \ddot{q} + G_j(\dot{q})] \ddot{q}^j = \sum_{j=1}^{m} \left[ \frac{\partial E_0}{\partial q^j} \dot{q}^j + \frac{\partial E_0}{\partial \dot{q}^j} \dddot{q}^j \right]$$

According to [8,20], the Birkhoffian (3.22) satisfies (2.10) with the function $E_0(q, \dot{q})$ given by (3.28) and the dissipative 1-form $D$ given by (3.24).

Let us now discuss the regularity of the Birkhoffian given by (3.22). If there exists in the network at least one loop that contains only capacitors, or only resistors, or only resistors and capacitors, then the Birkhoffian (3.22) associated to the network is never regular.
In [8] we have shown that if there exists at least one loop in an LC network that contains only capacitors, then the Birkhoffian associated to the network is never regular. The Birkhoffian associated to an RLC network which contains at least one loop formed only by resistors or only by resistors and capacitors is never regular as well. The proof is based on the fact that for the $l$-loop which does not contain any inductor branches, on the column $l$ of the matrix $A$ we have

$$A^a_l = 0, \quad a = r + 1, \ldots, r + k$$

(3.30)

For the Birkhoffian (3.22), the determinant in (2.8) becomes

$$\det \left[ \frac{\partial Q}{\partial \ddot{q}_j} (q, \dot{q}, \ddot{q}) \right]_{i,j=1,\ldots,m} = \det \left[ \sum_{a=r+1}^{r+k} \mathcal{N}^a_j \mathcal{N}^a_i \tilde{L}_{a-r} (\ddot{q}) \right]_{i,j=1,\ldots,m}$$

(3.31)

From (3.31), we get

$$\sum_{a=r+1}^{r+k} \mathcal{N}^a_j \mathcal{N}^a_i \tilde{L}_{a-r} (\ddot{q}) = \sum_{i_1=1}^{m} \mathcal{C}^{i_1}_j \mathcal{C}^{i_1}_i \left[ \sum_{a=r+1}^{r+k} (A^a_i)^2 \tilde{L}_{a-r} (\ddot{q}) \right] + \sum_{1 \leq i_1 < i_2}^{m} (\mathcal{C}^{i_1}_j \mathcal{C}^{i_1}_i + \mathcal{C}^{i_2}_j \mathcal{C}^{i_2}_i) \left[ \sum_{a=r+1}^{r+k} A^a_i A^a_j \tilde{L}_{a-r} (\ddot{q}) \right]$$

(3.32)

Using basic calculus, the determinant of the matrix with the elements (3.32), is a linear combination of determinants having at least two linearly dependent columns. This shows that the determinant in the right hand side of (3.31) is equal to zero. Thus, the Birkhoffian (3.22) is not regular.

We now discuss the question, how to proceed in the case than the Birkhoffian given by (3.22) is not regular in the sense of definition (2.8).

If there exists in the network $m_1 < m$ loops which contain only capacitors, all the other loops containing at least an inductor, we can regularize the Birkhoffian (3.22) via reduction of the configuration space. The reduced configuration space $\tilde{M}_c$ of dimension $m - m_1$, is a linear or a nonlinear subspace of $M_c$, depending on whether the capacitors are linear or nonlinear. We claim that the Birkhoffian $\tilde{\omega}_c$ on the reduced configuration space $\tilde{M}_c$ is still a dissipative Birkhoffian. Under certain conditions on the functions $L_a$, $a = 1, \ldots, k$, which characterize the inductors, the reduced Birkhoffian $\tilde{\omega}_c$ will be a regular Birkhoffian.

Without loss of generality, we can assume that there is one loop in the network that contains only capacitors and in the coordinate system we have chosen

$$\mathcal{N}^\Gamma_1 = 0, \quad \Gamma = 1, \ldots, r, \quad \mathcal{N}^a_1 = 0, \quad a = r + 1, \ldots, r + k$$

(3.33)

Thus, the Birkhoffian components (3.22), with (3.23), (3.24), (3.25), are given by, $j = 2, \ldots, m$. 

12
We will show that there exists a function $\bar{\mathcal{Q}}_L$ has the form $\bar{\mathcal{Q}}_L = \sum_{i=2}^{m} \sum_{a=r+k+1}^{b} \mathcal{N}^a_i \bar{C}_{a-r-k}(q)$.

(3.34)

We note that, according to (3.35), $\bar{q}^1$ does not appear in any function $\bar{R}_1(\bar{q})$, $\bar{L}_{a-r}(\bar{q})$ and the terms $\bar{L}_{a-r}(\bar{q})\bar{q}^1$ do not appear in any of the Birkhoffian components $Q_2(q, \dot{q}, \ddot{q})$, ..., $Q_m(q, \dot{q}, \ddot{q})$.

We define the $(m-1)$-dimensional nonlinear space $\bar{M}_c \subset M_c$ by

$$\bar{M}_c = \{ q \in M_c \mid \sum_{a=r+k+1}^{b} \mathcal{N}^a_i \bar{C}_{a-r-k}(q) = 0 \}$$

(3.35)

By the implicit function theorem, we obtain a local coordinate system on the reduced configuration space $\bar{M}_c$. Taking $\dot{q}^1 := q^2$, ..., $\dot{q}^{m-1} := q^m$, the Birkhoffian has the form $\bar{\omega}_c = \sum_{j=1}^{m-1} \bar{Q}_j \dot{q}^j$.

$$\bar{Q}_j(\bar{q}, \dot{q}, \ddot{q}) = \bar{F}_j(\bar{q}) \bar{q} + \bar{H}_j(\dot{q}) + \bar{G}_j(\ddot{q})$$

where

(3.36)

$$\bar{F}_j(\bar{q}) \bar{q} := \sum_{i=1}^{m-1} \sum_{a=r+k+1}^{b} \mathcal{N}^a_i \bar{C}_{a-r-k} \left( \mathcal{N}^a_j f(q^1, ..., q^{m-1}) + \sum_{l=1}^{m-1} \mathcal{N}^a_{l(l+1)} \dot{q}^l + \text{const} \right)$$

(3.37)

$$\bar{H}_j(\dot{q}) := \sum_{l=1}^{r} \mathcal{N}^a_j \bar{R}_l \left( \sum_{i=1}^{m-1} \mathcal{N}^a_{l(l+1)} \dot{q}^l \right)$$

(3.38)

$$\bar{G}_j(\ddot{q}) := \sum_{a=r+k+1}^{b} \mathcal{N}^a_j \bar{C}_{a-r-k} \left( \mathcal{N}^a_j f(q^1, ..., q^{m-1}) + \sum_{l=1}^{m-1} \mathcal{N}^a_{l(l+1)} \dot{q}^l + \text{const} \right)$$

(3.39)

$$f : U \subset \mathbb{R}^{m-1} \longrightarrow \mathbb{R}$$

being the unique function such that $f(\bar{q}_0) = q^1_0, q^0_0 \in \mathbb{R}$, and

$$\sum_{a=r+k+1}^{b} \mathcal{N}^a_j \bar{C}_{a-r-k} \left( \mathcal{N}^a_j f(q^1, ..., q^{m-1}) + \sum_{l=1}^{m-1} \mathcal{N}^a_{l(l+1)} \dot{q}^l + \text{const} \right) = 0$$

(3.40)

for all $\bar{q} = (q^1, ..., q^{m-1}) \in U$, with $U$ a neighborhood of $\bar{q}_0 = (q^1_0, ..., q^m_0)$.

We will now prove that the Birkhoffian (3.36) is dissipative. In order to do so, we will show that there exists a function $\bar{E}_{0, c}(\bar{q}, \dot{q})$ satisfying

$$\sum_{j=1}^{m-1} \bar{Q}_j(\bar{q}, \dot{q}, \ddot{q}) \dot{q}^j = \sum_{j=1}^{m-1} \left[ \frac{\partial \bar{E}_{0, c}}{\partial \bar{q}^j} \dot{q}^j + \frac{\partial \bar{E}_{0, c}}{\partial \dot{q}^j} \ddot{q}^j + \bar{D}_j(\bar{q}, \dot{q}) \dot{q}^j \right]$$

(3.41)

where $\bar{D} = \sum_{j=1}^{m-1} \bar{D}_j(\bar{q}, \dot{q}) \dot{q}^j$ is a dissipative 1-form on $T\bar{M}_c$. 

13
We consider the following 1-form on $T\bar{M}_c$

$$
\tilde{D} = \sum_{j=1}^{m-1} \sum_{\Gamma=1}^{r} \bar{H}_j(\tilde{q})d\tilde{q}^j
$$

(3.42)

In the view of the assumption (3.7), the vertical 1-form (3.42) on $T\bar{M}_c$ is dissipative, that is,

$$
\sum_{\Gamma=1}^{r} \left[ R_{\Gamma} \left( \sum_{j=1}^{m-1} N^r_{(j+1)}(\tilde{q}) \right) \right] \left( \sum_{j=1}^{m-1} \bar{N}^r_{(j+1)}(\tilde{q}) \right) > 0
$$

(3.43)

Therefore, (3.31) is fulfilled if $\bar{E}_{0\omega}(\tilde{q},\tilde{q})$ can be chosen in such a way that

$$
\sum_{j=1}^{m-1} \left[ \bar{F}_j(\tilde{q}) \tilde{q} + \tilde{G}_j(\tilde{q}) \right] \tilde{q}^j = \sum_{j=1}^{m-1} \left[ \frac{\partial \bar{E}_{0\omega}(\tilde{q})}{\partial \tilde{q}^j} + \frac{\partial \tilde{E}_{0\omega}(\tilde{q})}{\partial \tilde{q}^j} \right]
$$

(3.44)

is satisfied. Because of the special form of the terms on the left side of (3.44), we may assume that $\bar{E}_{0\omega}(\tilde{q},\tilde{q})$ is a sum of a function depending only on $\tilde{q}$, and a function depending only on $\tilde{q}$. From the theory of total differentials, a necessary condition for the existence of such functions is the fulfillment of the following relations

$$
\begin{cases}
\frac{\partial \bar{F}_j(\tilde{q})}{\partial \tilde{q}^j} - \frac{\partial \tilde{F}_j(\tilde{q})}{\partial \tilde{q}^j} = 0 \\
\frac{\partial \tilde{G}_j(\tilde{q})}{\partial \tilde{q}^j} - \frac{\partial \bar{G}_j(\tilde{q})}{\partial \tilde{q}^j} = 0
\end{cases}
$$

(3.45)

for any $j, l = 1, ..., m - 1$, where

$$
\bar{F}_j(\tilde{q}) := \sum_{i=1}^{m-1} \sum_{a=r+1}^{r+k} N^a_{(j+1)}N^a_{(i+1)}L_{a-r-r} \left( \sum_{i=1}^{m-1} N^a_{(i+1)} \tilde{q}^i \right) \tilde{q}^i
$$

(3.46)

From (3.30), we get:

$$
\frac{\partial \bar{F}_j(\tilde{q})}{\partial \tilde{q}^j} = \sum_{a=r+1}^{r+k} N^a_{(j+1)}N^a_{(i+1)} \bar{L}_{a-r}(\tilde{q}) + \sum_{i=1}^{m-1} \sum_{a=r+1}^{r+k} N^a_{(j+1)}N^a_{(i+1)} \bar{N}^a_{(i+1)} \bar{L}_{a-r}(\tilde{q}) \tilde{q}^i
$$

(3.47)

where $\bar{L}_{a-r} := \frac{d L_{a-r}(\tilde{q})}{d \tilde{q}^j}$. Then, the left side of the first relation in (3.45) becomes

$$
\sum_{a=r+1}^{r+k} \left[ \left( N^a_{(j+1)}N^a_{(i+1)} - N^a_{(i+1)}N^a_{(j+1)} \right) \bar{L}_{a-r}(\tilde{q}) + \left( N^a_{(j+1)}N^a_{(i+1)} - N^a_{(i+1)}N^a_{(j+1)} \right) \left( \sum_{i=1}^{m-1} N^a_{(i+1)} \tilde{q}^i \right) \bar{L}_{a-r}(\tilde{q}) \right]
$$

(3.48)
We easily see that the expression in (3.48) is zero, thus the first relation in (3.45) is fulfilled.

From (3.39), the second relation in (3.45) reads as

\[ \sum_{\alpha=r+k+1} b \alpha = r + k + 1 \]

where \( \tilde{C}_{\alpha, r-k} := \frac{d\tilde{C}_\alpha}{dq} \). The relation (3.49) reduces to

\[ \sum_{\alpha=r+k+1} \alpha = r + k + 1 \]

Taking into account (3.40), the above relation is fulfilled, for any \( j, l = 1, \ldots, m - 1 \). Indeed, taking the derivatives with respect to \( \bar{q}^j \) and also to \( \bar{q}^l \), in the equation (3.40), we obtain, respectively,

\[ \sum_{\alpha=r+k+1} \alpha = r + k + 1 \]

Now we multiply in (3.51) the first equation with \( \frac{\partial f(\bar{q})}{\partial \bar{q}^l} \), the second equation with \( -\frac{\partial f(\bar{q})}{\partial \bar{q}^j} \) and we add the resulting equations to obtain the equation (3.50).

Thus, we proved the existence of a function \( \bar{E}_{\omega}(\bar{q}, \dot{\bar{q}}, \ddot{\bar{q}}) \) such that (3.41) is fulfilled, with the dissipative 1-form given by (3.42). Therefore, the Birkhoffian (3.36) is dissipative.

For the Birkhoffian (3.36), the determinant in (2.8) becomes

\[ \det \left[ \alpha = r+k+1 \sum_{i,j=1,\ldots,m-1} N_{(i+1)}^\alpha \frac{\partial f(\bar{q})}{\partial \bar{q}^j} + N_{(j+1)}^\alpha \frac{\partial f(\bar{q})}{\partial \bar{q}^i} \right] = \det \left[ \sum_{a=r+1}^{r+k} \alpha = r+k+1 \sum_{i,j=1,\ldots,m-1} N_{(i+1)}^\alpha \alpha = r \frac{\partial f(\bar{q})}{\partial \bar{q}^j} + N_{(j+1)}^\alpha \frac{\partial f(\bar{q})}{\partial \bar{q}^i} \right] \]
which characterize the inductors, the reduced Birkhoffian \( \hat{\omega}_c \) will be a regular Birkhoffian.

Without loss of generality, we may assume that we have one loop in the network that contains only resistors and in the coordinate system that we have chosen, the constants read as

\[
N^a_\alpha = 0, \alpha = r + 1, \ldots, r + k, \quad N^a_1 = 0, a = r + k + 1, \ldots, b \tag{3.53}
\]

I) Let us first consider the case that the resistors in this loop are linear resistors, that is, described by (3.8), all the other electrical devices in the network being nonlinear. This means that we have

\[
N^T_\Gamma \neq 0, \quad \Gamma = 1, \ldots, r_{lin}, \quad N^T_1 = 0, \quad \Gamma = r_{lin} + 1, \ldots, r \tag{3.54}
\]

where \( r_{lin} \) is the number of linear resistors in the network.

In this case, the expressions of the Birkhoffian components (3.22), with (3.23), (3.24), (3.25), are given by,

\[
Q_1(q, \dot{q}, \ddot{q}) = \sum_{i=1}^{r_{lin}} \sum_{l=1}^{m} N^T_{\Gamma \Gamma} R_{\Gamma} N^T_{l \dot{q}^l} \\
Q_j(q, \dot{q}, \ddot{q}) = \sum_{i=2}^{m} \sum_{a=r+1}^{r+k} N^a_j N^a_{\Gamma} \tilde{L}_{a-r}(\dot{q}) \ddot{q}^a + \sum_{\Gamma=1}^{r_{lin}} \sum_{l=1}^{m} N^T_{\Gamma \Gamma} R_{\Gamma} N^T_{l \dot{q}^l} + \sum_{\Gamma=r_{lin}+1}^{r} N^T_{\Gamma \Gamma} \tilde{R}_{\Gamma}(\dot{q}) + \sum_{\alpha=r+k+1}^{b} N^a_{\Gamma} \tilde{C}_{a-r-k}(q) \tag{3.55}
\]

We note that according to (3.53), (3.54), \( \dot{q}^1 \) does not appear in any function \( R_{\Gamma}(\dot{q}), \tilde{L}_{a-r}(\dot{q}) \), the terms \( \tilde{L}_{a-r}(\dot{q})\ddot{q}^a \) do not appear in any of the Birkhoffian components \( Q_2(q, \dot{q}, \ddot{q}), \ldots, Q_m(q, \dot{q}, \ddot{q}) \) as well \( \dot{q}^1 \) does not appear in any function \( \tilde{C}_{a-r-k}(q) \).

We define the \((m-1)\)-dimensional linear space \( \hat{M}_c \subset M_c \) by

\[
\hat{M}_c = \{ q \in M_c | \sum_{\Gamma=1}^{r_{lin}} \sum_{l=1}^{m} N^T_{\Gamma \Gamma} R_{\Gamma} N^T_{l \dot{q}^l} + c_1 = 0 \} \tag{3.56}
\]

with \( c_1 \) a real constant.

We take \( \tilde{q}^1 := q^2, \ldots, \tilde{q}^{m-1} := q^m \), as local coordinates on the reduced configuration space \( \hat{M}_c \). Then, making use of (3.50) and of the fact that \( N^T_1 \neq 0 \) and \( R_{\Gamma} > 0 \), for any \( \Gamma = 1, \ldots, r_{lin} \), we can express \( \dot{q}^1 \) as a linear combination of \( \dot{\tilde{q}}^1, \ldots, \dot{\tilde{q}}^{m-1} \), denoted \( g(\tilde{q}) \), such that

\[
\sum_{\Gamma=1}^{r_{lin}} N^T_{\Gamma \Gamma} \left[ N^T_{1 \dot{q}^1} g(\tilde{q}) + \sum_{l=1}^{m-1} N^T_{(l+1) \dot{q}^l} \right] = 0 \tag{3.57}
\]

Thus, the reduced Birkhoffian has the form

\[
\hat{\omega}_c = \sum_{j=1}^{m-1} \hat{Q}_j d\tilde{q}^j, \\
\hat{Q}_j(\tilde{q}, \dot{\tilde{q}}, \ddot{\tilde{q}}) = \hat{F}_j(\tilde{q})\ddot{q} + \hat{H}_j(\dot{\tilde{q}}) + \hat{G}_j(\tilde{q}), \quad \text{where} \tag{3.58}
\]
\[ F_j(\dot{q})\ddot{q} := \sum_{i=1}^{m-1} \sum_{a=r}^{r+k} N^a_{(j+1)} N^a_{(i+1)} L_{a-r} \left( \sum_{l=1}^{m-1} N^a_{(l+1)q} \right) \ddot{q}^j \]  

(3.59)

\[ \dot{H}_j(\dot{q}) := \sum_{r=1}^{r_{lin}} N_{(j+1)}^T R_{\Gamma} \left[ N^T_1 g(\dot{q}) + \sum_{l=1}^{m-1} N^T_{(l+1)q} \dot{q}^j \right] + \sum_{r=1}^{r_{lin}+1} N_{(j+1)}^T R_{\Gamma} \left( \sum_{l=1}^{m-1} N^T_{(l+1)q} \dot{q}^j \right) \]  

(3.60)

\[ G_j(\dot{q}) := \sum_{\alpha=r+k+1}^b N^\alpha_{(j+1)} C_{\alpha-r-k} \left( \sum_{l=1}^{m-1} N^\alpha_{(l+1)q} + \text{const} \right) \]  

(3.61)

The Birkhoffian given by (3.58) is still dissipative. We will see that there exists a function \( \dot{E}_{0,\omega}(\dot{q}, \ddot{q}) \) such that

\[ m_{a-1} \sum_{j=1}^{m-1} \dot{Q}_j(\dot{q}, \ddot{q}q) \]  

(3.62)

\[ \dot{H}_j(\dot{q}) \dot{q}^j > 0 \]  

(3.64)

From (3.60), the left side of (3.64) writes as the sum \( S_1 + S_2 \), where

\[ S_1 = \sum_{j=1}^{m-1} R_{\Gamma} \left[ N^T_1 g(\dot{q}) + \sum_{l=1}^{m-1} N^T_{(l+1)q} \dot{q}^j \right] \dot{q}^j \]  

(3.55)

\[ S_2 = \sum_{r=1}^{r_{lin}+1} R_{\Gamma} \left( \sum_{j=1}^{m-1} N^T_{(j+1)q} \dot{q}^j \right) \left( \sum_{j=1}^{m-1} N^T_{(j+1)q} \dot{q}^j \right) \]  

(3.66)

We now multiply the equation (3.57) by the function \( g(\dot{q}) \). Using the resulting equation we can write the sum in (3.65) in the form

\[ S_1 = \sum_{r=1}^{r_{lin}} R_{\Gamma} \left[ N^T_1 g(\dot{q}) + \sum_{l=1}^{m-1} N^T_{(l+1)q} \dot{q}^j \right]^2 \]  

(3.67)
Since $r_\Gamma > 0$, $\Gamma = 1, \ldots, r_{\text{lin}}$, the sum $S_1$ is strictly positive. Because all nonlinear resistors considered satisfy the condition $3.71$, the sum $S_2$ in $3.63$ is strictly positive as well. Therefore, the inequality $3.63$ is fulfilled and the vertical 1-form in $3.63$ is dissipative.

We now look for a function $E_{0_\downarrow}(\dot{q}, \ddot{q})$ such that

$$
\sum_{j=1}^{m-1} \left[ F_j(\dot{q})\dot{q} + G_j(\dot{q}) \right] \dot{q}^j = \sum_{j=1}^{m-1} \left[ \frac{\partial E_{0_\downarrow}(\dot{q})}{\partial \dot{q}^j} + \frac{\partial E_{0_\downarrow}(\dot{q})}{\partial \dot{q}^j} \right]
$$

(3.68)

Because of the special form of the terms on the left side of $3.68$, we can look for the required function $E_{0_\downarrow}(\dot{q}, \ddot{q})$ as a sum of a function only depending on $\dot{q}$, and a function only depending on $\ddot{q}$. From the theory of total differentials, a necessary condition for the existence of such functions is the fulfillment of the following relations

$$
\begin{align*}
\frac{\partial \hat{F}_j(\dot{q})}{\partial \dot{q}^j} - \frac{\partial \hat{F}_j(\ddot{q})}{\partial \ddot{q}^j} &= 0 \\
\frac{\partial \hat{G}_j(\dot{q})}{\partial \dot{q}^j} - \frac{\partial \hat{G}_j(\ddot{q})}{\partial \ddot{q}^j} &= 0
\end{align*}
$$

(3.69)

for any $j, l = 1, \ldots, m - 1$, where

$$
\hat{F}_j(\dot{q}) = \sum_{r=1}^{m-1} \sum_{a=r+1}^{m-1} N_{a}^{a} N_{r}^{a} \bar{L}_{a-r}(\dot{\hat{q}}) \left( \sum_{i=1}^{m-1} N_{a}^{a} \dot{q}^i \right) \dot{q}^j
$$

(3.70)

From $3.70$, $3.61$ we get

$$
\frac{\partial \hat{F}_j(\dot{q})}{\partial \dot{q}^j} = \sum_{a=r+1}^{m-1} \sum_{a=r+1}^{m-1} N_{a}^{a} N_{r}^{a} \bar{L}_{a-r}(\dot{\hat{q}}) + \sum_{i=1}^{m-1} \sum_{a=r+1}^{m-1} N_{a}^{a} N_{r}^{a} \bar{C}_{a-r-k}(\dot{\hat{q}})
$$

(3.71)

$$
\frac{\partial \hat{G}_j(\dot{q})}{\partial \dot{q}^j} = \sum_{a=r+1}^{m-1} \sum_{a=r+1}^{m-1} N_{a}^{a} N_{r}^{a} \bar{C}_{a-r-k}(\dot{\hat{q}})
$$

(3.72)

where $\bar{L}_{a-r} := \frac{d\bar{L}_{a-r}(\dot{q})}{d\dot{q}^j}$, $\bar{C}_{a-r-k} := \frac{d\bar{C}_{a-r-k}(\dot{q})}{d\dot{q}^j}$. We can easily check that the equations $3.69$ are fulfilled.

Thus, we proved the existence of a function $E_{0_\downarrow}(\dot{q}, \ddot{q})$ such that $3.63$ is fulfilled, with the dissipative 1-form given by $3.63$ that is, the Birkhoffian $3.68$ is dissipative.

For the Birkhoffian $3.68$, the determinant in $3.68$ becomes

$$
\det \left[ \frac{\partial Q_j}{\partial \dot{q}^j}(\ddot{q}, \dot{q}, \ddot{q}) \right]_{j=1}^{m-1} = \det \left[ \sum_{a=r+1}^{m-1} N_{a}^{a} N_{r}^{a} \bar{L}_{a-r}(\dot{\hat{q}}) \right]
$$

(3.73)

If the determinant in $3.68$ is different from zero, then the Birkhoffian $3.68$ is regular. ■
II) Let us now consider the case that the resistors in the loop formed only by resistors are nonlinear devices too, that is, they are described by (3.6), with the assumption \[6\]. Now, instead of (3.5) we have \(N^r_1 \neq 0\), \(\Gamma = 1, \ldots, r\). The component \(Q_1(q, \dot{q}, \ddot{q})\) of the Birkhoffian takes the form

\[
Q_1(q, \dot{q}, \ddot{q}) = \sum_{l=1}^{r} N^r_1 R_l(q)
\]

and the other components \(Q_2(q, \dot{q}, \ddot{q}), \ldots, Q_m(q, \dot{q}, \ddot{q})\) are the same as in (3.56) with the terms following \(r_{lin} = 0\) absent. According to (3.58), \(\dot{q}^1\) does not appear in any function \(L_{a-r}(\dot{q})\), the terms \(L_{a-r}(\dot{q})\dot{q}^1\) do not appear in any of the Birkhoffian components \(Q_2(q, \dot{q}, \ddot{q}), \ldots, Q_m(q, \dot{q}, \ddot{q})\) as well \(q^1\) does not appear in any function \(C_{a-r-k}(q)\).

Using (3.74), we intend to define the \((m-1)\)-dimensional configuration space \(M_c \subset M_e\). The relation (3.74) is a nonlinear velocity constraint, which in general is a nonholonomic constraint. Nevertheless, because of this constraint imposed on the system, the equations which describe the dynamics are \(Q_2(q, \dot{q}, \ddot{q}) = 0, \ldots, Q_m(q, \dot{q}, \ddot{q}) = 0\).

Taking \(\tilde{q}^1 := q^2, \ldots, \tilde{q}^{m-1} := q^m\), a coordinate system on the reduced configuration space \(M_e\), the Birkhoffian has in this case the form \(\bar{Q}_c = \sum_{j=1}^{m-1} \tilde{Q}_j d\tilde{q}^j\),

\[
\bar{Q}_j(\tilde{q}, \dot{\tilde{q}}, \ddot{\tilde{q}}) = \sum_{i=1}^{m-1} \sum_{a=r+1}^{r+k} N^a_{(j+1)} N^a_{(i+1)} L_{a-r} \left( \sum_{l=1}^{m-1} N^a_{(i+1)} \dot{\tilde{q}}^l \right) \dot{\tilde{q}}^i + \sum_{l=1}^{r} N^r_{(j+1)} R_l \left( N^r_1 h(\dot{\tilde{q}}, \ldots, \tilde{q}^{m-1}) + \sum_{l=1}^{m-1} N^r_{(l+1)} \dot{\tilde{q}}^l \right) + \sum_{a=r+k+1}^{b} N^a_{(j+1)} C_{a-r-k} \left( \sum_{i=1}^{m-1} N^a_{(i+1)} \dot{\tilde{q}}^l \right) \tag{3.75}
\]

where \(h : U \subset \mathbb{R}^{m-1} \rightarrow \mathbb{R}\) is the unique function such that \(h(\dot{\tilde{q}}) = \dot{q^1}_0, \dot{q^1}_0 \in \mathbb{R},\) and

\[
\sum_{l=1}^{r} N^r_{(j+1)} R_l \left( N^r_1 h(\dot{\tilde{q}}, \ldots, \tilde{q}^{m-1}) + \sum_{l=1}^{m-1} N^r_{(l+1)} \dot{\tilde{q}}^l \right) = 0 \tag{3.76}
\]

for all \(\dot{\tilde{q}} = (\dot{q}^1, \ldots, \dot{q}^{m-1}) \in U,\) with \(U\) a neighborhood of \(\dot{q}_0 = (\dot{q}^1_0, \ldots, \dot{q}^{m-1}_0).\)

One can prove using the same ideas as in the previous case, that the Birkhoffian given by (3.75) is still dissipative.

If the determinant \(\det \left[ \sum_{a=r+1}^{r+k} N^a_{(j+1)} N^a_{(i+1)} L_{a-r} \left( \dot{\tilde{q}} \right) \right]_{i,j=1,\ldots,m-1} \neq 0\), then, the Birkhoffian (3.75) is regular. ■

If there exists in the network \(m_3 < m\) loops which contain only resistors and capacitors, all the other loops containing at least an inductor, we can \textit{regularize} the Birkhoffian (3.22) by introducing into each of these \(m_3\) loops, an inductor in series, with the inductance functions \(L_{a'} : \mathbb{R} \rightarrow \mathbb{R} \setminus \{0\}, a' = 1, \ldots, m_3,\) having
very small values. The configuration space remains $M_c$ of dimension $m$, under certain conditions on the functions $\mathcal{L}_{\alpha}$ and on the functions $L_a$, $a = 1, ..., k$, which characterize the others inductors, the Birkhoffian $\omega^e_{\text{ext}}$ on $M_c$ will be a **dissipative regular Birkhoffian**.

Without loss of generality, we may assume that we have one loop in the network containing only resistors and capacitors and in the chosen coordinate system

$$N_1^a = 0, \ a = r + 1, ..., r + k \quad (3.77)$$

The expressions (3.22) of the Birkhoffian components become, $j = 2, ..., m$.

$$Q_1(q, \dot{q}, \ddot{q}) = \sum_{\Gamma=1}^{r} N_{\Gamma}^1 \tilde{R}_{\Gamma}(\dot{q}) + \sum_{a=r+k+1}^{b} N_1^a \tilde{C}_{a-r-k}(q)$$

$$Q_j(q, \dot{q}, \ddot{q}) = \sum_{i=2}^{m} \sum_{a=r+1}^{r+k} N_j^a N_{i}^1 \tilde{L}_{a-r}(\dot{q}) \ddot{q} + \sum_{\Gamma=1}^{r} N_{\Gamma}^j \tilde{R}_{\Gamma}(\dot{q}) + \sum_{a=r+k+1}^{b} N_j^a \tilde{C}_{a-r-k}(q) \quad (3.78)$$

We introduce into this loop an inductor in series, described by the following relation between the current and the voltage

$$v = \mathcal{L}_1(1) \frac{di}{dt} \quad (3.79)$$

$\mathcal{L}_1 : \mathbb{R} \rightarrow \mathbb{R} \setminus \{0\}$ being smooth invertible function. After introducing the inductor, the number of branches of the graph associated to the circuit increases by one, that is, there will be $b + 1$ branches, and the number of nodes increases by one as well, that is, $n$ becomes $n + 1$. Still the cardinality of a selection of loops which cover the whole graph remains $m$. The configuration space is the same $M_c$, with dimension $m$. The corresponding Birkhoffian, denoted by $\omega^e_{\text{ext}}$, has the component $Q_1(q, \dot{q}, \ddot{q})$ given by,

$$Q_1(q, \dot{q}, \ddot{q}) = \tilde{L}(\dot{q}_1) \ddot{q}_1 + \sum_{\Gamma=1}^{r} N_{\Gamma}^1 \tilde{R}_{\Gamma}(\dot{q}) + \sum_{a=r+k+1}^{b} N_1^a \tilde{C}_{a-r-k}(q) \quad (3.80)$$

the others $Q_2(q, \dot{q}, \ddot{q}),..., Q_m(q, \dot{q}, \ddot{q})$ have the same form as in (3.78). This Birkhoffian is dissipative, the expression of the function $E_{0,\omega}$ on $TM_c$ is $\mathcal{E}_0$ plus the term $\int \tilde{L}(\dot{q}_1) \ddot{q}_1 d^1$. The dissipative 1-form has the form (3.26). If $\tilde{L}(\dot{q}_1) \det \left[ \sum_{a=r+1}^{r+k} N_{(j+1)} \tilde{N}_{(i+1)} \tilde{L}_{a-r}(\dot{q}) \right]_{1, j=1, ..., m-1} \neq 0$, this Birkhoffian is regular.

### 3.2 Voltage controlled resistors

Let us now consider the nonlinear resistors for which the constitutive relations are given by

$$i_\Gamma = \Re_{\Gamma}(v_\Gamma), \quad \Gamma = 1, ..., r \quad (3.81)$$
where $\mathcal{R}_\Gamma : \mathbb{R} \rightarrow \mathbb{R}$ are smooth functions. In order to obtain a dissipative Birkhoffian, we also assume that, for all $x \neq 0$,

$$\mathcal{R}_\Gamma(x)x > 0, \quad \forall \Gamma = 1, ..., r$$

(3.82)

that is, for each nonlinear resistor, the graph of the function $\mathcal{R}_\Gamma$ lies in the union of the first and the third quadrant.

Taking into account (3.3), (3.4), (3.5), (3.81), the equations (3.1), (3.2) governing the circuit have the form

$$
\begin{align*}
B^T \begin{pmatrix}
I_\Gamma \\
\dot{t}_\alpha \\
\dot{q}_\alpha 
\end{pmatrix} &= 0 \\
A^T \begin{pmatrix}
v_\Gamma \\
L_\alpha(t_\alpha) \dot{t}_\alpha \\
C_\alpha(q_\alpha) 
\end{pmatrix} &= 0 \\
I_\Gamma &= \mathcal{R}_\Gamma(v_\Gamma)
\end{align*}
$$

(3.83)

Using the first set of equations (3.83), we define a family of $m$-dimensional affine-linear configuration spaces $M_c \subset \mathbb{R}^b$ parameterized by a constant vector $c$ in $\mathbb{R}^n$. This vector is related to the initial values of the $q$-variables at some instant of time. A Birkhoffian $\omega_c$ on the configuration space $M_c$ arises from the second set of equations (3.83). Thus, $(M_c, \omega_c)$ will be a family of Birkhoff systems that describe the considered RLC network.

The first set of equations (3.83) is the same as the first set of equations (3.9). Thus, using them we can define the family $M_c$ of $m$-dimensional affine-linear configuration spaces (3.11). For a coordinate system $q = (q_1, ..., q_m)$ on $M_c$, the relations between the $x$-coordinates (3.14) and the $q$-coordinates are given by (3.15). The matrix of constants $N$ satisfies (3.16). Taking into account (3.20), we define the Birkhoffian $\omega_c$ of $M_c$ such that the differential system (2.5) is the linear combination of the second set of equations in (3.83) obtained by replacing $A^T$ with the matrix $N^T$. In terms of the $q$-coordinates chosen before, the components $Q_j(q, \dot{q}, \ddot{q})$ of the Birkhoffian have the implicit form

$$
\begin{align*}
Q_j(q, \dot{q}, \ddot{q}) &= F_j(\dot{q})\ddot{q} + G_j(q) + \sum_{\Gamma=1}^r N^\Gamma_j v_\Gamma, \quad j = 1, ..., m \\
\sum_{j=1}^m N_j^\Gamma \dot{q}^j &= \mathcal{R}_\Gamma(v_\Gamma)
\end{align*}
$$

(3.84)

where the functions $F_j(\dot{q})\ddot{q}, G_j(q)$ are given by (3.23), (3.25).

The Birkhoffian (3.84) is dissipative.

Indeed, with the function $E_{0,\Gamma}(q, \dot{q})$ given by (3.28), the identity (2.16) becomes for the Birkhoffian (3.84),

$$
\sum_{j=1}^m Q_j(q, \dot{q}, \ddot{q}) \ddot{q}^j = \sum_{j=1}^m \left[ \frac{\partial E_{0,\Gamma}}{\partial q^j} \dot{q}^j + \frac{\partial E_{0,\Gamma}}{\partial \dot{q}^j} \ddot{q}^j + \sum_{\Gamma=1}^r N^\Gamma_j v_\Gamma \dot{q}^j \right]
$$

(3.85)
It remains to show that the vertical 1-form defined implicitly by
\[
\begin{align*}
D_j(q, \dot{q}) &= \sum_{\Gamma=1}^r N_j^\Gamma v_\Gamma, \quad j = 1, \ldots, m \\
\sum_{j=1}^m N_j^\Gamma \dot{q}^j &= \mathcal{R}_\Gamma(v_\Gamma)
\end{align*}
\] (3.86)
is dissipative. From the second set of relations in (3.86), we have
\[
\sum_{j=1}^m \sum_{\Gamma=1}^r N_j^\Gamma v_\Gamma \dot{q}^j = R_\Gamma(v_\Gamma)
\] (3.87)
Therefore, the inequality (2.14) reads as \( \sum_{\Gamma=1}^r \mathcal{R}_\Gamma(v_\Gamma)v_\Gamma > 0 \). The last inequality is satisfied in view of the assumption (3.82). ■

As in the case of current controlled sources, the Birkhoffian (3.84) is never regular if the network contains closed loops formed only by capacitors, or resistors, or both of them.

4 Examples

Example 1): This example is based on the following oriented connected graph

We have \( r = 1, \quad k = 3, \quad p = 3, \quad n = 3, \quad m = 4, \quad b = 7 \). We choose the reference node to be \( V_4 \) and the current directions as indicated in Figure 1. We cover the associated graph with the loops \( I_1, I_2, I_3, I_4 \). Let \( V = (V_1, V_2, V_3) \in \mathbb{R}^3 \) be the vector of node voltage values, \( \mathbf{i} = (i_1, i_2, i_3) \in \mathbb{R}^3 \times \mathbb{R}^3 \times \mathbb{R}^3 \) be the vector of branch current values and \( \mathbf{v} = (v_1, v_2, v_3) \in \mathbb{R}^3 \times \mathbb{R}^3 \times \mathbb{R}^3 \) be the vector of branch voltage values.

The branches in Figure 1 are labelled as follows: the first branch is the resistive branch \( \mathbf{r}_1 \), the second, the third and the fourth branch are the inductive branches \( \mathbf{l}_1, \mathbf{l}_2, \mathbf{l}_3 \) and the last three branches are the capacitor branches \( \mathbf{c}_1, \mathbf{c}_2, \mathbf{c}_3 \). The incidence and loop matrices, \( B \in \mathcal{M}_{73}(\mathbb{R}) \) and \( A \in \mathcal{M}_{74}(\mathbb{R}) \), write
\[ B = \begin{pmatrix} -1 & 0 & 1 \\ 0 & 0 & -1 \\ 0 & -1 & 0 \\ 0 & -1 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad A = \begin{pmatrix} 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & -1 \\ 0 & 1 & -1 & 0 \\ 0 & 0 & 1 & 0 \\ -1 & 1 & 0 & 0 \\ 1 & 0 & 0 & -1 \end{pmatrix} \] (4.1)

One has \( \text{rank}(B) = 3, \text{rank}(A) = 4. \)

All the electrical devices are considered to be nonlinear and described by the relations, (3.3), (3.5), with \( C_1, C_2, C_3 : \mathbb{R} \to \mathbb{R}\backslash\{0\}, L_1, L_2, L_3 : \mathbb{R} \to \mathbb{R}\backslash\{0\} \)
smooth invertible functions and by the relation (3.6), with \( R_1 : \mathbb{R} \to \mathbb{R} \)
smooth function, such that (3.7) is satisfied, that is, for any \( x \neq 0 \)
\[ R_1(x)x > 0 \] (4.2)

The equations (3.9) which govern the network have the form
\[ \begin{align*}
- i[1] + \dot{q}_2 - \dot{q}_3 &= 0 \\
- i(2) - i(3) + \dot{q}_1 + \dot{q}_3 &= 0 \\
\dot{i}[1] - i(1) + i(3) &= 0 \\
&C_1(q_1) + C_2(q_2) + C_3(q_3) = 0 \\
&L_2(i(2))i(2) + C_1(q_1) = 0 \\
&L_1(i(1))i(1) - L_2(i(2))i(2) + L_3(i(3))i(3) = 0 \\
&- R_1(i[1]) - L_1(i(1))i(1) - C_2(q_2) = 0 \\
\end{align*} \] (4.3)

The relations (3.12), (3.14) read as follows for this example
\[ \begin{align*}
i[1] := \dot{q}[1], &\quad i(a) := \dot{q}(a), \quad a = 1, 2, 3 \\
x^1 := q[1], &\quad x^2 := q(1), \quad x^3 := q(2), \quad x^4 := q(3), \quad x^5 := q_1, \quad x^6 := q_2, \quad x^7 := q_3 \\
\end{align*} \] (4.4)

Using the first 3 equations of the system (4.3) we define the 4-dimensional affine-linear configuration space \( M_c. \) In view of the notations (4.4), (4.5), we integrate these 3 equations and solving them in terms of 4 variables, we obtain, for example, \( x^2 = x^1 + x^4 + \text{const}, \quad x^5 = x^3 + x^4 - x^7 + \text{const}, \quad x^6 = x^1 + x^7 + \text{const}. \)

Thus, a coordinate system on \( M_c \) is given by
\[ \begin{align*}
q^1 := x^7, &\quad q^2 := x^4, \quad q^3 := x^1, \quad q^4 := x^3 \\
\end{align*} \] (4.6)
The matrix of constants $\mathbf{N} = \left( \begin{array}{cccc} N^\Gamma_1 & N^\Gamma_2 & \cdots & N^\Gamma_7 \\ N^\gamma_1 & N^\gamma_2 & \cdots & N^\gamma_7 \\ N^\alpha_1 & N^\alpha_2 & \cdots & N^\alpha_7 \end{array} \right)$ from (4.5) is given by

$$
\mathbf{N} = \begin{pmatrix}
0 & 0 & 1 & 0 \\
0 & 1 & 1 & 0 \\
0 & 0 & 0 & 1 \\
0 & 1 & 0 & 0 \\
-1 & 1 & 0 & 1 \\
1 & 0 & 1 & 0 \\
1 & 0 & 0 & 0
\end{pmatrix}.
$$

Therefore, in terms of the $q$-coordinates (4.6), we may define the Birkhoffian $\omega_e = Q_1(q, \dot{q}, \ddot{q}) dq^1 + Q_2(q, \dot{q}, \ddot{q}) dq^2 + Q_3(q, \dot{q}, \ddot{q}) dq^3 + Q_4(q, \dot{q}, \ddot{q}) dq^4$ of $\Gamma$ as in (3.22), with (3.23), (3.24), (3.25), that is,

$$
\begin{align*}
Q_1(q, \dot{q}, \ddot{q}) &= -C_1(-q^1 + q^2 + q^4 + \text{const}) + C_2(q^1 + q^3 + \text{const}) + C_3(q^1) \\
Q_2(q, \dot{q}, \ddot{q}) &= [L_1(q^2 + q^3) + L_3(q^2)] q^2 + L_1(q^2 + q^3) q^3 + C_1(-q^1 + q^2 + q^4 + \text{const}) \\
Q_3(q, \dot{q}, \ddot{q}) &= L_1(q^2 + q^3) q^2 + L_1(q^2 + q^3) q^3 + R_1(q^3) + C_2(q^1 + q^3 + \text{const}) \\
Q_4(q, \dot{q}, \ddot{q}) &= L_2(q^2) q^1 + C_1(-q^1 + q^2 + q^4 + \text{const})
\end{align*}
$$

(4.7)

The Birkhoffian (4.7) is dissipative and not regular.

Indeed, there exists a smooth function $E_{0_e} : TM \rightarrow \mathbb{R}$ of the form (3.28), that is,

$$
E_{0_e}(q, \dot{q}) = \int \tilde{L}_1(q^2, q^3)(q^2 + q^3)(dq^2 + dq^3) + \int \tilde{L}_2(q^4) dq^4 + \int \tilde{L}_3(q^2) dq^3 - \\
\int \int \tilde{L}_1(q^2, q^3)(q^2 + q^3) dq^2 dq^3 - \int \int \tilde{L}_1(q^2, q^3) dq^2 dq^3 + \\
\int \tilde{C}_1(q^1, q^2, q^4)(dq^1 + dq^4) + \int \tilde{C}_2(q^1, q^3)(dq^1 + dq^3) +
\int \int \tilde{C}_3(q^1) dq^1 - \int \int \tilde{C}_4(q^1, q^2, q^4)(-dq^1 dq^2 + dq^1 dq^4 - dq^2 dq^4) - \\
\int \int \tilde{C}_5(q^1, q^2, q^4) dq^1 dq^2 - \int \int \tilde{C}_6(q^1, q^2, q^4) dq^3 dq^4
$$

(4.8)

such that (4.10) is satisfied with

$$
D = R_1(q^3) dq^3
$$

(4.9)

Because the function $R_1$ satisfies (1.2), we obtain

$$
D_j(q, \dot{q}) q^j = R_1(q^3) q^3 > 0
$$

(4.10)

that is, (4.8) is indeed a dissipative vertical 1-form.

We are in the case where the circuit considered has one loop which contains only capacitors. We note that for the Birkhoffian (4.7), the first row of the matrix

$$
\left[ \frac{\partial Q}{\partial q^i} \right]_{i,j=1,2,3,4}
$$

contains only zeros. Therefore, \( \det \left[ \frac{\partial Q}{\partial q^i} \right]_{i,j=1,2,3,4} = 0 \) and the
Using the first relation in (4.7), we now define a 3-dimensional Birkhoffian (4.7) is not regular.

By the implicit function theorem, we obtain a local coordinate system on the reduced configuration space $\tilde{M}_c$. Taking $\bar{q}^1 := q^2, \bar{q}^2 := q^3, \bar{q}^3 := q^4$, the Birkhoffian has the form $\tilde{\omega}_c = \sum_{j=1}^3 \tilde{Q}_j \tilde{q}^j$, where

$$
\tilde{Q}_1(\bar{q}, \dot{\bar{q}}, \ddot{\bar{q}}) = \left[ L_1(\bar{q}^1 + \dot{\bar{q}}^1) + L_3(\dot{\bar{q}}^1) \right] \dot{\bar{q}}^1 + L_1(\dot{\bar{q}}^1 + \dot{\bar{q}}^2)\dot{\bar{q}}^2 - C_1(f(\dot{\bar{q}}^1, \dot{\bar{q}}^2, \dot{\bar{q}}^3) - \bar{q}^1 + \dot{\bar{q}}^3 + \text{const})
$$

$$
\tilde{Q}_2(\bar{q}, \dot{\bar{q}}, \ddot{\bar{q}}) = L_1(\bar{q}^1 + \dot{\bar{q}}^1)\dot{\bar{q}}^1 + L_1(\bar{q}^1 + \dot{\bar{q}}^2)\dot{\bar{q}}^2 + R_1(\dot{\bar{q}}^2) + C_2(f(\dot{\bar{q}}^1, \dot{\bar{q}}^2, \dot{\bar{q}}^3) + \dot{\bar{q}}^2 + \text{const})
$$

$$
\tilde{Q}_3(\bar{q}, \dot{\bar{q}}, \ddot{\bar{q}}) = L_2(\dot{\bar{q}}^3)\dot{\bar{q}}^3 + C_1(f(\dot{\bar{q}}^3, \dot{\bar{q}}^3, \dot{\bar{q}}^1) - \dot{\bar{q}}^1 + \dot{\bar{q}}^3 + \text{const})
$$

Taking $\bar{q} := (\bar{q}^1, \bar{q}^2, \bar{q}^3)$ in $U$, with $U$ a neighborhood of $\bar{q} = (\bar{q}^1, \bar{q}^2, \bar{q}^3) \in U$, such that $\tilde{Q}_1(\bar{q}, \dot{\bar{q}}, \ddot{\bar{q}}) = 0$, $\forall \bar{q} = (\bar{q}^1, \bar{q}^2, \bar{q}^3) \in U$. We have shown in section 3 that in this case the reduced Birkhoffian (4.12) is dissipative and regular.

The relations (4.25) are satisfied for this example, thus, there exists a function $E_{0,\circ}(\bar{q}, \dot{\bar{q}})$ such that (4.11) is fulfilled, with the dissipative 1-form given by

$$
D = R_1(\dot{\bar{q}}^2)d\bar{q}^2
$$

We calculate

$$
\det \begin{bmatrix} \frac{\partial Q_j}{\partial \dot{q}^i} \end{bmatrix}_{i,j=1,2,3} = \begin{vmatrix} L_1(\dot{\bar{q}}^1 + \dot{\bar{q}}^2) + L_3(\dot{\bar{q}}^1) & L_1(\dot{\bar{q}}^1 + \dot{\bar{q}}^2) & 0 \\ L_1(\dot{\bar{q}}^1 + \dot{\bar{q}}^2) & L_1(\dot{\bar{q}}^1 + \dot{\bar{q}}^2) & 0 \\ 0 & 0 & L_2(\dot{\bar{q}}^3) \end{vmatrix}
$$

Because $L_1, L_2, L_3: \mathbb{R} \rightarrow \mathbb{R}\setminus\{0\}$, the determinant above is different from zero, then, the reduced Birkhoffian given by (4.12) is regular.

If the nonlinear resistor is voltage controlled, that is, $I_{[1]} = R_1(\dot{q}_1)$

we obtain, instead of (4.7), the following implicit Birkhoffian

$$
\begin{aligned}
Q_1(q, \dot{q}, \ddot{q}) &= C_1(q^1 - q^2 + q^4 + \text{const}) + C_2(q^1 + q^3 + \text{const}) + C_3(q^4) \\
Q_2(q, \dot{q}, \ddot{q}) &= \left[ L_1(q^2 + \dot{q}^2) + L_3(\dot{q}^2) \right] \dot{q}^2 + L_1(q^2 + \dot{q}^3)\dot{q}^3 - C_1(q^1 - q^2 + q^4 + \text{const}) \\
Q_3(q, \dot{q}, \ddot{q}) &= L_1(q^2 + \dot{q}^2)\dot{q}^2 + L_1(q^2 + \dot{q}^3)\dot{q}^3 + C_2(q^1 + q^3 + \text{const}) + v_1 \\
Q_4(q, \dot{q}, \ddot{q}) &= L_2(q^4)\dot{q}^4 + C_1(q^4 - q^2 + q^4 + \text{const}) \\
\dot{q}^3 &= R_1(\dot{q}_1)
\end{aligned}
$$

(4.16)
We suppose that the nonlinear voltage controlled resistor satisfies $R_1(x) > 0$, for any $x \neq 0$. Thus, as in the case of current controlled resistors, there exists a function $E_0(q, \dot{q})$ given by (4.8), such that (4.16) is satisfied with the dissipative implicit 1-form

$$
\begin{cases}
D(q, \dot{q}) = v_1 dq^3, \\
\dot{q}^3 = R_1(v)
\end{cases}
$$

(4.17)

Therefore, the Birkhoffian (4.16) is dissipative. The Birkhoffian (4.16) is also not regular. ■

Example 2) This example is based on the following oriented connected graph

We have $r = 5$, $k = 2$, $p = 2$, $n = 5$, $m = 4$, $b = 9$. We choose the reference node to be $V_6$ and the current directions as indicated in Figure 2. We cover the associated graph with the loops $I_1$, $I_2$, $I_3$, $I_4$. Let $V = (V_1, V_2, V_3, V_4, V_5) \in \mathbb{R}^5$ be the vector of node voltage values, $i = (i_{(a)}, i_{(a)}, i_{(a)}) \in \mathbb{R}^5 \times \mathbb{R}^2 \times \mathbb{R}^2$ be the vector of branch current values and $v = (v_{(a)}, v_{(a)}, v_{(a)}) \in \mathbb{R}^5 \times \mathbb{R}^2 \times \mathbb{R}^2$ be the vector of branch voltage values.

The branches in Figure 2 are labelled as follows: the first, the second and the third branch are the linear resistive branches, $R_{lin_1}$, $R_{lin_2}$, $R_{lin_3}$, the fourth and the fifth branch are the nonlinear resistive branches $R_4$, $R_5$, the second, the sixth and the seventh branch are the inductive branches $L_1$, $L_2$, and the last two branches are the capacitor branches $C_1$, $C_2$. The incidence and loop matrices, $B \in \mathfrak{M}_{95}(\mathbb{R})$ and $A \in \mathfrak{M}_{94}(\mathbb{R})$, write as

$$
B = \begin{pmatrix}
0 & -1 & 1 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & -1 & 0 & 0 \\
0 & 0 & 0 & 0 & -1 \\
0 & 0 & -1 & 1 & 0 \\
-1 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & -1 & 1 \\
\end{pmatrix}, \quad
A = \begin{pmatrix}
1 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & -1 \\
1 & -1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 \\
\end{pmatrix}
$$

(4.18)

One has $\text{rank}(B) = 5$, $\text{rank}(A) = 4$. Except from the resistors in the first loop which are considered linear, all devices
are nonlinear and are described by the relation (3.3), (3.5), (3.6). We suppose
that $R_1, R_2, R_3 > 0$, are distinct constants, $C_1, C_2 : \mathbb{R} \to \mathbb{R}\setminus\{0\}$, $L_1, L_2 : \mathbb{R} \to \mathbb{R}\setminus\{0\}$, smooth invertible functions and $R_4, R_5 : \mathbb{R} \to \mathbb{R}$ smooth functions such that, for any $x \neq 0$

$$R_4(x)x > 0, \quad R_5(x)x > 0 \quad (4.19)$$

The first set of equations (3.9) has the form

$$\begin{cases}
-t_{(1)} + \dot{Q}_1 = 0 \\
-t_{[1]} + I_{[2]} + I_{(1)} = 0 \\
I_{[1]} - I_{[3]} - I_{[5]} = 0 \\
I_{[5]} + I_{(2)} - \dot{Q}_2 = 0 \\
-I_{[4]} + \dot{Q}_2 = 0
\end{cases} \quad (4.20)$$

The relations (3.12), (3.14) read as follows for this example

$$I_{[1]} := \dot{Q}_{[1]}, \quad \Gamma = 1, \ldots, 5, \quad I_{(a)} := \dot{Q}_{(a)}, \quad a = 1, 2 \quad (4.21)$$

$x^1 := Q_{[1]}, \ldots, x^5 := Q_{[5]}, \quad x^6 := Q_{(1)}, \quad x^7 := Q_{(2)}, \quad x^8 := Q_1, \quad x^9 := Q_2 \quad (4.22)$

Using the equations from (4.20), we define the 4-dimensional affine-linear configuration space $M_c$. In view of the notations (4.21), (4.22), we integrate these 5 equations and solving them in terms of 4 variables, we obtain, for example,

$$x^2 = x^1 - x^8 + \text{const}, \quad x^3 = x^1 - x^5 + \text{const}, \quad x^4 = x^9 + \text{const}, \quad x^6 = x^8 + \text{const}, \quad x^7 = -x^5 + x^9 + \text{const}.$$ 

Thus, a coordinate system on $M_c$ is given by

$$q^1 := x^1, q^2 := x^5, q^3 := x^8, q^4 := x^9 \quad (4.23)$$

The matrix of constants $\mathcal{N}$ from (3.14) is given by

$$\mathcal{N} = \begin{pmatrix}
1 & 0 & 0 & 0 \\
1 & 0 & -1 & 0 \\
1 & -1 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{pmatrix}. \quad \text{Therefore, in terms of the $q$-coordinates (4.23), we define the Birkhoffian $\omega_c = Q_1(q, \dot{q}, \ddot{q})dq^3 + Q_2(q, \dot{q}, \ddot{q})dq^2 + Q_3(q, \dot{q}, \ddot{q})dq^4 + Q_4(q, \dot{q}, \ddot{q})dq^4$ of $M_c$ as in } (3.22), \text{ with } (3.23), (3.24), (3.25), \text{ that is,}$

$$Q_1(q, \dot{q}, \ddot{q}) = (r_1 + r_2 + r_3)\dot{q}^2 - r_3\ddot{q}^2 - r_2\dddot{q}^3$$

$$Q_2(q, \dot{q}, \ddot{q}) = L_2(-q^2 + \dot{q}^4)\dot{q}^2 - L_2(-q^2 + \dot{q}^4)\dddot{q}^4 - r_3\dot{q}^1 + r_3\dot{q}^2 + R_5(q^2)$$

$$Q_3(q, \dot{q}, \ddot{q}) = L_1(q^3)\dot{q}^3 - r_2\dot{q}^1 + r_2\dot{q}^2 + C_1(q^3)$$

$$Q_4(q, \dot{q}, \ddot{q}) = -L_2(-q^2 + \dot{q}^4)\ddot{q}^2 + L_2(-q^2 + \dot{q}^4)\dddot{q}^4 + R_4(q^3) + C_2(q^4) \quad (4.24)$$

The Birkhoffian (4.24) is dissipative and not regular.

Indeed, there exists a smooth function $E_{0_c} : TM \to \mathbb{R}$ of the form (3.28), that
is,

\[
E_0(q, \dot{q}) = \int L_1(\dot{q}^3)q^3 \, dq^3 + \int \widetilde{L}_2(q^2, q^4)(-\dot{q}^2 + \dot{q}^4)(-dq^2 + dq^4) - \\
\int \int \widetilde{L}_2(q^2, q^4)(-\dot{q}^2 + q^4) dq^2 \, dq^4 + \int \int \widetilde{L}_2(q^2, q^4) dq^2 \, dq^4 + \\
\int C_1(q^3) dq^3 + \int C_2(q^4) dq^4
\]

such that (4.14) is satisfied with the dissipative 1-form defined by

\[
D = \left[ q^1 R_1 + \left( q^1 - q^3 \right) R_2 + q^1 \right] dq^1 + \left[ -\left( q^1 - q^2 \right) R_3 + \right. \\
R_5(q^2) \right] dq^2 - \left( q^1 - q^2 \right) R_2 dq^3 + R_4(q^4) dq^4
\]

(4.25)

In view of the assumptions (4.19) and of \( R_1, R_2, R_3 > 0 \), we get

\[
D_j(q, \dot{q})q^j = R_1(q^1)^2 + R_2(q^1 - q^3)^2 + R_3(q^1 - q^2)^2 + R_4(q^4) q^4 + R_5(q^2) q^2 > 0
\]

(4.27)

Therefore, the vertical 1-form in (4.26) is dissipative.

We are in the case where the considered circuit has one loop which contains only resistors. We note that for the Birkhoffian (4.24), the first row of the matrix

\[
\left[ \frac{\partial Q_j}{\partial q^i} \right]_{i,j=1,...,4}
\]

contains only zeros. Therefore, \( \det \left[ \frac{\partial Q_j}{\partial q^i} \right]_{i,j=1,...,4} = 0 \) and the Birkhoffian (4.24) is not regular.

Using the first relation in (4.24), we now define \( \dot{M}_c \subset M_c \) by

\[
\dot{M}_c = \{ q = (q^1, q^2, q^3, q^4) \in M_c / (R_1 + R_2 + R_3) q^1 - R_3 q^2 - R_2 q^3 + c_1 = 0 \}
\]

(4.28)

where \( c_1 \) is a real constant.

On the reduced configuration space \( \dot{M}_c \), in the coordinate system given by \( \dot{q}^1 := q^2, \dot{q}^2 := q^3, \dot{q}^3 := q^4 \), the Birkhoffian has the form \( \dot{\omega}_c = \dot{Q}_1(q^1) + \dot{Q}_2(q^2) + \dot{Q}_3(q^3) \)

\[
\dot{Q}_1(q, \dot{q}, \ddot{q}) = L_1(-\dot{q}^1 + 3\dot{q}^3) - L_2(-\dot{q}^1 + \dot{q}^3)\dot{q} + (\mathcal{E}_2 + \mathcal{E}_3)\dot{q}^1 - \mathcal{E}_3 \dot{q}^2 + R_5(q^1) \\
\dot{Q}_2(q, \dot{q}, \ddot{q}) = L_1(\dot{q}^2)^2 - \mathcal{E}_3 \dot{q}^1 + (\mathcal{E}_1 + \mathcal{E}_3)\dot{q}^2 + C_1(q^2) \\
\dot{Q}_3(q, \dot{q}, \ddot{q}) = -L_2(-\dot{q}^1 + 3\dot{q}^3)\dot{q} + L_2(-\dot{q}^1 + \dot{q}^3)\dot{q}^3 + R_4(q^3) + C_2(q^3)
\]

(4.29)

where we denote the constants \( \mathcal{E}_1 := \frac{R_1 R_2}{R_1 + R_2 + R_3}, \mathcal{E}_2 := \frac{R_1 R_3}{R_1 + R_2 + R_3}, \mathcal{E}_3 := \frac{R_2 R_3}{R_1 + R_2 + R_3} \).

As we have stated in section 3, the Birkhoffian given by (4.24) is still dissipative. The function \( E_0(q, \dot{q}) \) has the same form (4.25) written in the coordinates \( \dot{q} \). The relation (4.30) is satisfied with the dissipative 1-form defined by

\[
\dot{D} = \left[ \dot{q}^1 \mathcal{E}_2 + (\dot{q}^1 - \dot{q}^3) \mathcal{E}_3 + R_5(q^1) \right] dq^1 + \left[ \dot{q}^2 \mathcal{E}_1 - (\dot{q}^1 - \dot{q}^2) \mathcal{E}_3 \right] dq^2 + \\
R_4(q^3) dq^3
\]

(4.30)
The vertical 1-form above is dissipative, as can be seen as follows: For \( r_1 > 0, r_2 > 0, r_3 > 0 \), we get \( C_1 > 0, C_2 > 0, C_3 > 0 \) and together with \( (1.19) \), yield

\[
\hat{D}_j(q, \dot{q}) \hat{q}_j = C_2(q)^1 1^2 + C_3(q)^1 1^2 + C_4(q)^2 1 + R_2(q)^1 0 + R_4(q)^3 3 > 0 \quad (4.31)
\]

The Birkhoffian given by \( (4.29) \) is not regular, since the determinant

\[
\det \left[ \frac{\partial \hat{Q}_j}{\partial \dot{q}_j} \right]_{i,j=1,2,3} = \begin{vmatrix}
\tilde{L}_2(\dot{q}) & 0 & -\tilde{L}_2(\dot{q}) \\
0 & \tilde{L}_1(\dot{q}) & 0 \\
-\tilde{L}_2(\dot{q}) & 0 & \tilde{L}_2(\dot{q})
\end{vmatrix} = 0 \quad (4.32)
\]

This result does not come unexpected because the considered network has also a loop which contains only resistors and capacitors, formed by \( R_4, C_2, R_5, R_{\text{lin}} \). In order to regularize the Birkhoffian \( (4.29) \), we introduce an inductor in series into this loop, described by the following relation between the current and the voltage: \( v = L_1(t) \frac{d}{dt}, \quad L_1 : \mathbb{R} \longrightarrow \mathbb{R}\{0\} \) being smooth invertible function. This means that this loop will have one more node and one more branch. The number of branches for the graph associated to the circuit, increases by one, that is, there will be \( b = 10 \) branches, and the number of nodes increases by one as well, that is, we will have \( n = 6 \). But the cardinality of a selection of loops which cover the whole graph remains \( m = 4 \). After the calculation we arrive at the reduced configuration space defined by \( (4.28) \). On the reduced configuration space \( \hat{M}_c \), in the coordinate system given by \( \tilde{q}^1 := q^2, \tilde{q}^2 := q^3, \tilde{q}^3 := q^4 \), the Birkhoffian \( \hat{\omega}_c^{\text{ext}} \) has the components \( \hat{Q}_1(\tilde{q}, \dot{\tilde{q}}, \ddot{\tilde{q}}), \hat{Q}_2(\tilde{q}, \dot{\tilde{q}}, \ddot{\tilde{q}}) \) given by \( (4.29) \) and the expression of \( \hat{Q}_3(\tilde{q}, \dot{\tilde{q}}, \ddot{\tilde{q}}) \) becomes

\[
\hat{Q}_3(\tilde{q}, \dot{\tilde{q}}, \ddot{\tilde{q}}) = -L_2(\dot{\tilde{q}}^1 + \dot{\tilde{q}}^3 1^3) + \left[ L_1(\dot{\tilde{q}}^3) + L_2(\dot{\tilde{q}}^1 + \dot{\tilde{q}}^3) \right] \dot{\tilde{q}}^3 +
R_4(\dot{\tilde{q}}^3) + C_2(\dot{\tilde{q}}) \quad (4.33)
\]

We now calculate

\[
\det \left[ \frac{\partial \hat{Q}_j}{\partial \ddot{q}_j} \right]_{i,j=1,2,3} = \begin{vmatrix}
\tilde{L}_2(\dot{q}) & 0 & -\tilde{L}_2(\dot{q}) \\
0 & \tilde{L}_1(\dot{q}) & 0 \\
-\tilde{L}_2(\dot{q}) & 0 & \tilde{L}_2(\dot{q}) + \tilde{L}_2(\dot{q})
\end{vmatrix} = 0 \quad (4.34)
\]

Because \( L_1, L_1, L_2 : \mathbb{R} \longrightarrow \mathbb{R}\{0\} \), the determinant above is different from zero, then, the Birkhoffian \( \hat{\omega}_c^{\text{ext}} \) is regular.
