metallo-β-lactamases (Ambler Classes A, B, C, and D). In this analysis, we evaluated the activity of ceftolozane (FEP) in combination with VNRX-5133 and comparators against 1,120 recent Enterobacteriaceae clinical isolates, including carbapenem-resistant strains.

**Methods.** MICs of FEP in combination with VNRX-5133 fixed at 4 µg/mL (FEP/VNRX-5133) were determined following CLSI M7-A10 guidelines against 1,120 Enterobacteriaceae from community and hospital infections collected globally in 2012–2013. Resistant phenotypes were based on 2017 CLSI breakpoints. As FEP/VNRX-5133 breakpoints have not yet been established, the FEP 2 g q8h susceptible dose-dependent (SDD) breakpoint of ≤8 µg/mL was considered for comparative purposes.

**Results.** FEP/VNRX-5133 showed potent activity against drug-resistant subsets of Enterobacteriaceae, with MIC50 values ranging from 1 µg/mL against ceftazidime-, levofloxacin-, or piperacillin-tazobactam-nonsusceptible isolates, to 8 µg/mL against meropenem-nonsusceptible isolates. FEP/VNRX-5133 inhibited >93% of all resistant subsets at ≤50 µg/mL.

**Conclusion.** Ceftolozane in combination with VNRX-5133 demonstrated potent in vitro activity against Enterobacteriaceae, including cephalosporin-, fluoroquinolone- and carbapenem-resistant (CRE) isolates. Because this drug combination exhibited substantial potential for the treatment of infections caused by isolates often resistant to first-line therapy, the development is warrant for further investigation.

1361. **Pharmacokinetics and Safety of Ridinilazole (RDZ), a Potential New Therapy for Clostridium difficile Infection (CDI): From Animal Models to Patients**

**Background.** CDI is the leading cause of nosocomial diarrhea associated with 29,000 deaths p.a. in the United States. RDZ is a novel oral drug highly selective for *C. difficile* limiting collateral damage to the gut microbiota. Here we present a combined analysis of all pharmacokinetic (PK) and tolerability data obtained throughout the development of RDZ from animal models to Phase 2, including new human PK data.

**Methods.** RDZ levels were measured in plasma and in the GI tract of infected hamsters after a single oral dose at 25 mg/kg. Quantitative whole-body autoradiography (QWBA) and excretion mass balance studies were performed in rats following a single 50 mg/kg oral dose of 13C RDZ. In GLP toxicology studies, RDZ was administered orally for 28 days to GLP toxicology studies, RDZ was administered orally for 28 days to GLP animals to test safety. Both clinical trials quantified RDZ in plasma and feces, and assessed safety and tolerability.

**Results.** In all animal studies, plasma levels of RDZ were below or at the limit of quantification (LOQ, 1.0 ng/mL). In the GI tract of hamsters, RDZ levels were highest in the colon. In the 28-day study, RDZ levels were greater than or near the LOQ (0.1 ng/mL). Concomitant medications, CDI severity, and age had no impact on exposure. In Phase 1, AEs were mild with no dose-dependent relationship, occurring and at a similar incidence to placebo. No significant findings from clinical laboratory, ECGs or other assessment were observed. RDZ was well tolerated in Phase 2 with the incidence of AEs and SAEs similar in both RDZ and VNA groups.

**Conclusion.** In both clinical and nonclinical studies to date, RDZ has been well tolerated and associated with low systemic absorption. Further assessment of safety and tolerability, and PK in Phase 3 studies is warranted.

1362. **A Novel Intravesical Antimicrobial for CAUTIs**

**Background.** As many as 1.5 million people reside in long-term care facilities in the United States. Nearly all of these patients will develop catheter-associated urinary tract infections (CAUTIs) during their stay in a skilled nursing facility. These infections collectively cost the healthcare system billions of dollars each year. In addition, the emergence of multidrug-resistant ESCAPE (Enterobacteriaceae species, Staphylococcus aureus, Klebsiella species, Acinetobacter baumanii, Pseudomonas aeruginosa, and Enterococcus species) pathogens affects the severity of infections, increasing both morbidity and mortality. Our research group is exploring a novel, dual-acting, antimicrobial, glycerol monolaurate (GML)-containing gel to prevent and treat CAUTIs.

**Methods.** Pieces (7 mm in length) of Remaf Silicone Tubing were placed in the bladders of BALB/c female mice (n = 5/group). Approximately 1 x 10⁷ colony-forming units/mL (CFU/mL) were injected into the bladder, and animals were returned to cages for 18 hours. Three hundred microliters of 2.5% GML Gel (50:50 mix of saline and human-approved glycols) or phosphate-buffered saline (PBS) was administered into the bladder. After 18 hours, animals were euthanized and colony-forming units in bladders and on catheters were determined, and histological analysis of bladders was performed.

**Results.** GML Gel was bactericidal against ESCAPE pathogens at 2 hours post-treatment. Subsequent histological analysis of bladders from infected and noninfected mice showed that GML Gel was not toxic to bladder tissue.

**Conclusion.** Our results in this murine catheter infection model indicate that the newly formulated GML Gel may be useful in prevention and treatment of CAUTIs.

1363. **Sulopenem Activity Against Enterobacteriaceae Isolates From Patients With Urinary Tract Infection or Intra-Abdominal Infection**

**Background.** Sulopenem is a thienam antibiotic with oral and parenteral formulations being developed for the treatment of urinary tract infection (UTI) or complicated intra-abdominal infection (cIAI). The activity of sulopenem aligns with the most urgent drug-resistant antimicrobial threats defined by the Centers for Disease Control (CDC), including ESBL-producing strains of *Escherichia coli* and *Klebsiella* species. We evaluated the in vitro antibacterial activity of sulopenem against clinical Enterobacteriaceae isolates from patients in North America with UTI or cIAI collected during 2016–2017.

**Methods.** Sulopenem and other antimicrobial agents were tested for *in vitro* activity against 1,008 recent (2016–2017) consecutive Enterobacteriaceae isolates collected through the SENTRY Antimicrobial Surveillance Program from patients in North America with UTI (906 isolates) or cIAI (102 isolates). Reference broth microdilution susceptibility testing was conducted using frozen-form panels produced by the Center for Disease Control (CDC) and ESBL-producing strains of *Escherichia coli* and *Klebsiella pneumoniae* to evaluate the clinical utility of sulopenem against clinical Enterobacteriaceae isolates from patients in North America with UTI or cIAI collected during 2016–2017.

**Results.** Table 1. Activity of sulopenem and comparator antimicrobial agents against 1,008 Enterobacteriaceae North American isolates

| Antibiotic | MIC<sub>50</sub> µg/mL | %<sub>50</sub> | %<sub>1</sub> | %<sub>R</sub> | MIC<sub>90</sub> µg/mL |
|------------|-----------------|-------------|---------|---------|-----------------|
| Sulopenem  | 0.03            | 0.03        | 0.00    | 0.00    | 0.25            |
| Meropenem  | 0.25            | 0.25        | 0.00    | 0.00    | 2.00            |
| Ertapenem  | 0.03            | 0.03        | 0.00    | 0.00    | 0.06            |
| Ceftriaxone| 8.00            | 8.00        | 0.00    | 0.00    | 16.00           |
| Piperacillin-tazobactam | 2.00 | 2.00 | 0.00 | 0.00 | 4.00 |
| Amoxicillin-clavulanate (2:1) | 16.00 | 16.00 | 0.00 | 0.00 | 32.00 |
| Levofloxacin | 0.10 | 0.10 | 0.00 | 0.00 | 0.50 |

The sulopenem MIC<sub>50</sub> and MIC<sub>90</sub> values for *Enterobacteriaceae* were 0.03/0.25 µg/mL. For *Escherichia coli*, *Klebsiella pneumoniae* and *Proteus mirabilis*, the MIC<sub>50</sub> and MIC<sub>90</sub> results were 0.03/0.03 µg/mL, 0.03/0.06 µg/mL, and 0.12/0.25 µg/mL, respectively.

**Conclusion.** Sulopenem demonstrated potent in *vivo* activity against organisms commonly implicated in UTI and cIAI. These data support the further clinical development of sulopenem for Gram-negative infections.
