Abstract

Pyrroloquinone ring systems are important structural units present in many biologically active molecules including a number of marine alkaloids. For example, they are found in a series of marine metabolites, such as tsitsikammamines, zyzzyanones, wakayin, and terreusinone. Several of these alkaloids have exhibited antimicrobial, antimalarial, antifungal, antitumor, and photoprotecting activities. Synthesis of pyrroloquinone unit is the key step in the synthesis of many of these important organic molecules. Here, we present a ceric (IV) ammonium nitrate (CAN) mediated oxidative free radical cyclization reaction of 1,3-dicarbonyl compounds with aminoquinones as a facile methodology for making various substituted pyrroloquinones. 1,3-dicarbonyl compounds used in this study are ethyl acetoacetate, acetylacetone, benzoyl acetone, and N,N-dimethyl acetoacetamide. The aminoquinones used in this study are 2-(benzylamino)naphthalene-1,4-dione and 6-(benzylamino)-1-tosyl-1H-indole-4,7-dione. The yields of the synthesized pyrroloquinones ranged from 23–91%.

1. Introduction

Pyrroloquinone is a pharmacophore present in many biologically important molecules. For example, a family of marine alkaloids that include zyzzyanones, tsitsikamminamine, and wakayin contains the pyrroloquinone skeleton [1–4]. These alkaloids are metabolites of marine sponges Latrunculia, Zyzzya and ascidian species Clavelina [1, 4–6]. In addition to antimicrobial, antimalarial, and antifungal activities, these alkaloids have notable antitumor properties, which are derived from their unique fused ring structure. Tsitsikammamine A
derivatives, for example, inhibit indoleamine-2,3-dioxygenase, an important enzyme contributing to tumor immune invasion [7]. Tsitsikammamines A-B also exhibit antimicrobial, antimalarial, and antifungal properties, cytotoxicity, and topoisomerase inhibition [8]. Additionally, marine alkaloid wakayin inhibits topoisomerase II, damages DNA, exhibits strong antimicrobial property against Bacillus subtilis, and is potent toward human colon cancer cell lines [1]. Zyzzyanones A-D contain a bispyrroloquinone ring system and have exhibited cytotoxicity against Ehrlich carcinoma cells at micromolar range [2, 3]. Moreover, bispyrroloquinone is also the core structure of the marine fungus metabolite terreusinone (1), which is a potent UV-A protectant [9]. The photoprotecting activity of terreusinone is stronger than that of the commercial sunscreen ingredient oxybenzone [10]. For these reasons, pyrroloquinone alkaloids are regarded as a source of new antitumor and dermatological drugs [11–17].

Unfortunately, these natural products are isolated from natural sources only in minute quantities, which impose a limitation on their thorough biological evaluation. Additionally, the unique fused-ring aromatic structure poses a challenge in the total synthesis of these natural products. Several efforts have been made towards achieving the synthesis of these natural products [8, 10, 17, 19]. Our group has recently used an oxidative free radical cyclization reaction as a key step in the synthesis of zyzzyanones and the intermediates [19, 20].

Oxidative free radical reactions facilitated by transition metals have been known to promote carbon-carbon bond formation. In these reactions, the electron transfer between the radical precursor and metal complex generates electrophilic radicals, which ultimately react with alkenes, alkynes, or quinones to form carbon-carbon bonds [21–26]. Among the metal salts that have been investigated in the past two decades for facilitating oxidative free radical cyclization, Mn-(OAc)$_3$ and ceric (IV) ammonium nitrate (CAN) were proven to be the most efficient catalysts. A proposed mechanism of action for these reagents for effecting oxidative free radical cyclization has also been reported [21, 27, 28]. Mn-(OAc)$_3$ and CAN have been extensively used in the synthesis of naphthoquinone, which is an important skeleton of natural products, such as mitosenes, kinamycins, and murrayaquinones [29, 30]. The synthesis of bispyrroloquinone by a CAN mediated oxidative free radical cyclization has been reported from our lab [20]. An Mn(OAc)$_3$ mediated oxidative free radical cyclization leading to the total synthesis of zyzzyanones A-D has also been reported from our lab [19]. As an extension of these studies, herein, we demonstrate the general synthetic utility of CAN mediated oxidative free radical cyclization of various aminoquinones with 1,3-dicarbonyl compounds to form 24 new substituted pyrroloquinones.

2. Results and Discussion

The oxidative free radical reaction leading to the formation of pyrroloquinones is shown in the general Table 1. Substituted benzylaminoquinones such as 2-
(benzylamino)naphthalene-1,4-dione (8) and 6-(benzylamino)-1-tosyl-1H-indole-4,7-dione (10) are treated with various 1,3-dicarbonyl compounds in the presence of CAN to afford 24 pyrroloquinone derivatives (4a-l and 5a-l) in moderate to excellent yields.

We used various 2-benzylaminonaphthalene-1,4-diones (8a–c) and N-Tosyl-6-benzylaminoinodole-4,7-quinones (10a–c) as starting substrates for our oxidative free radical reactions yielding pyrroloquinones. Three 2-benzylamino naphthalene-1,4-diones (8a–c) used in these studies were prepared as outlined in Scheme 1. Naphthalene-1,4-dione (7) was treated with substituted benzyl amines (6a–c) in a mixture of MeOH and THF to afford 2-benzylamino naphthalene-1,4-diones (8a–c) in 50–86% yield.

The three N-Tosyl-6-benzylaminoinodole-4,7-quinones (10a–c) used in these studies were prepared as outlined in Scheme 2. Previously reported [31], N-Tosyl-6-methoxyindole-4,7-quinone (9) was treated with substituted benzyl amines (6a–c) in a mixture of MeOH and THF to afford N-Tosyl-6-benzylaminoinodole-4,7-quinones (10a–c) in 70–94% yield.

Yields and the specific reaction conditions used for the oxidative free radical cyclization of the aminoquinones (8a–c and 10a–c) with four 1,3-dicarbonyl compounds are summarized in Figure 4. 1,3-dicarbonyl compounds used in this study are ethyl acetoacetate, acetylacetone, benzoyl acetone and N,N-dimethyl acetoacetamide. The reactions resulted in the formation of 24 new substituted pyrroloquinones with yields ranging from 23% to 91%. Most of these reactions were carried out in CH₂Cl₂ and MeOH, except for entries 2 and 3 where a combination of CH₂Cl₂ and EtOH was used as solvent. Initially, the reaction of 8a with 4 equivalents of ethyl acetoacetate yielded the expected product 4a in good yield (80%, entry 1). However, latter reactions employed fewer equivalents of β-carbonyl compounds, which tended to result in cleaner reactions and made purification easier. Unfortunately, when compound 8b reacted with ethyl acetoacetate in CH₂Cl₂ and MeOH, the reaction proceeded well, but a mixture of methyl and ethyl esters was obtained due to transesterification. So, a combination of CH₂Cl₂ and EtOH was used in these cases to obtain the products, 4b and 4c in 35% and 82%, respectively (entries 2 and 3).

The majority of pyrroloquinones 4a-l were obtained in good yields regardless of the types of β-carbonyl starting materials used. The products 4a-l were usually yellow compared to the red orange starting materials 8a–c. Additionally, we experimented with 1, 1.8, and 4 equivalents of β-carbonyl compounds and found that only 1 equivalent of β-carbonyl compounds was sufficient to bring the reaction to the completion. Highest yields were obtained when the electron donating methoxy group was present on the benzyl substituent (entries 3, 6, 9, and 12, 82–91% yield). In contrast, the presence of nitro group on the benzyl group resulted in significantly lower yields (entries 2, 5, 8, and 11, 31–38% yield). Entries with unsubstituted benzyl substituents resulted in moderate yields (entries 1, 4, 7, and 10, 51–80%). The reactions of 8b with all four 1,3-dicarbonyl compounds proved to be difficult. This is due to several reasons, firstly, poor solubility of 8b in CH₂Cl₂ and MeOH which required the usage of triple amount of solvent volume and heating to dissolve the starting material. Secondly, the reaction did not proceed at room temperature as in the other cases and needed refluxing to force the reactions to go to completion. In addition, more CAN (1.5–2.5 equiv) and longer reaction times were required for the reaction to go to completion.

J Chem. Author manuscript; available in PMC 2015 February 18.
Finally, the reactions always resulted in a significant amount of side products, which ultimately led to low product yields.

When 1,3-diketones such as acetylacetone and benzoylacetone are used in these experiments, theoretically, two regioisomeric products are possible. The two possible products (A and B) for the reaction between benzoylacetone and 2-benzylamino naphthalene-1,4-dione mediated by CAN are illustrated in Figure 2. However, only one product (4g) was formed in this reaction, and it was proved to be the isomer A by \(^1\)H-NMR, \(^{13}\)C-NMR, and NOESY experiments. In the NOESY NMR experiment of compound 4g as indicated in Figure 3, the methyl group (CH\(_3\); singlet; 2.18 ppm) clearly had a NOESY correlation with the benzyl methylene group (CH\(_2\); singlet; 5.76 ppm). The experiment clearly establishes that the product formed is regioisomer A. The absence of the regioisomer B is perhaps due to the steric hindrance between the two bulky phenyl groups, which makes the structure significantly more unstable.

Compounds 10a–c were reacted with the 1,3-dicarbonyl reagents, including ethyl acetoacetate, benzoyl acetone, N,N-dimethyl acetoacetamide, and acetylacetone. The reactions were carried out in the 1 : 5 ratio mixtures of CH\(_2\)Cl\(_2\) and MeOH. The yields and reaction condition to obtain the final products 5a-l are given in Figure 4. In this study, four equivalents of CAN were necessary for the reactions to complete while less equivalents or absence of CAN resulted in the incomplete or no reactions. The types of 1,3-dicarbonyl reagents did not affect the outcome of the reaction as there were no trends affecting percent yields when different \(\beta\)-carbonyl reagents were used. Interestingly, the reaction of 6-(benzylamino)-1-tosyl-1H-indole-4,7-dione with 1,3-diketones is expected to yield two regioisomeric products, but only one product was formed as in the case of 2-(benzylamino)naphthalene-1,4-dione system.

Although the trend is not as strong as in previous 2-(benzylamino)naphthalene-1,4-dione system, the yields of the methoxybenzyl-substituted products 5c, f, i, and l (entries 15, 18, 21, and 24, 65–71%) are slightly higher than those of the nonsubstituted counterparts 5a, d, g, and j (entries 13, 16, 19, and 22, 67–68%). In addition, the nonsubstituted bispyrroloquinones 5a, d, g, and j were achieved in better yields compared to their equivalent nitrobenzyl substituted compounds 5b, e, h, and k (entries 14, 17, 20, and 23, 52–60%). These results were consistent with our earlier observation in the reactions of 2-benzylaminonaphthalene-1,4-diones.

3. Conclusions

Synthesis of pyrroloquinone unit is the key step in the synthesis of several biologically important organic molecules. A CAN mediated oxidative free radical cyclization reaction of 1,3-dicarbonyl compounds with aminooquinones leading to the formation of various substituted pyrroloquinones is presented. 1,3-dicarbonyl compounds used in this study are acetylacetone, benzoyl acetone, ethyl acetoacetate, and N,N-dimethyl acetoacetamide. The aminooquinones used in this study are 2-(benzylamino)naphthalene-1,4-dione and 6-(benzylamino)-1-tosyl-1H-indole-4,7-dione. The yields of the synthesized pyrroloquinones ranged from 23 to 91%. Interestingly, we found that only one regioisomer was formed even
when 1,3-diketones like benzoyl acetone were used. Finally, the majority of the oxidative free radical cyclized products were isolated as yellow solids in good yields.

4.1. General Considerations

The NMR spectra were recorded on a Bruker DPX 300, DRX 400, or AVANCE 700 spectrometers. Chemical shifts are reported in ppm relative to TMS or CDCl$_3$ as internal standard. The values of chemical shift ($\delta$) and coupling constants $J$ were given in parts per million and in Hz, respectively. Mass spectra were recorded using an Applied Biosystems 4000Q Trap and Micromass Platform LCC instruments. Thin-layer chromatography was performed with silica gel plates with fluorescent indicator (Whatman, silica gel, UV254, and 25 $\mu$m plates) and visualized by UV (wavelengths 254 and 365 nm). The reaction mixture was purified by column chromatography using silica gel (32–63 $\mu$m) from Dynamic Absorbent Inc. Melting points were uncorrected and obtained from Mel-Temp II apparatus. Solvents were removed 
in vacuo
by using rotatory evaporator. The recrystallization was assisted by Fisher Scientific FS30 sonicator. Anhydrous solvents were purchased in Sure-Seal bottles from Aldrich chemical company. Other reagents were obtained from Aldrich and Acros chemical companies.
