Quantum Blue and Woody Breast myopathy

Quantum blue reduces the severity of Woody Breast myopathy via modulation of oxygen homeostasis-related genes in broiler chickens

Abstract

The incidence of woody breast (WB) is increasing on a global scale representing a significant welfare problem and economic burden to the poultry industry and for which there is no effective treatment due to its unknown etiology. In this study, using diffuse reflectance spectroscopy (DRS) coupled with iSTAT portable clinical analyzer, we provide evidence that the circulatory-and breast muscle-oxygen homeostasis is dysregulated (low oxygen and hemoglobin levels) in chickens with WB myopathy compared to healthy counterparts. Molecular analysis showed that blood hemoglobin subunit Mu (HBM), Zeta (HBZ), and hephaestin (HEPH) expression were significantly down regulated, however the expression of the subunit rho of hemoglobin beta (HBBR) was upregulated in chicken with WB compared to healthy counterparts. The breast muscle HBBR, HBE, HBZ, and hypoxia-inducible factor prolyl hydroxylase 2 (PHD2) mRNA abundances were significantly down regulated in WB-affected compared to normal birds. The expression of HIF-1α at mRNA and protein levels was significantly induced in breasts of WB-affected compared to unaffected birds confirming a local hypoxic status. The phosphorylated levels of the upstream mediators AKT at Ser473 site, mTOR at Ser2481 site, and PI3K P85 at Tyr458 site, as well as their mRNA levels were significantly increased in breasts of WB-affected birds.

In attempt to identify a nutritional strategy to reduce WB incidence, male broiler chicks (Cobb 500, n = 576) were randomly distributed into 48 floor pens and subjected to six treatments (12 birds/pen; 8 pens/treatment): a nutrient adequate control group (PC), the PC supplemented with 0.3% myo-inositol (PC+MI), a negative control (NC) deficient in available P and Ca by 0.15 and 0.16%, respectively, the NC fed with quantum blue (QB) at 500 (NC+ 500 FTU), 1,000 (NC+ 1,000 FTU) or 2,000 FTU/kg of feed (NC+ 2,000 FTU). Although QB-enriched diets did not affect growth performances (FCR and FE), it did reduce the severity of WB by 5% compared to the PC diet. This effect is mediated by reversing the expression profile of oxygen
homeostasis-related genes; i.e. significant down regulation of HBBR and upregulation of HBM, HBZ, and HEPH in blood, as well as a significant upregulation of HBA1, HBBR, HBE, HBZ, and PHD2 in breast muscle compared to the positive control.

**Keywords:** Quantum blue, woody breast, growth performance, hypoxia, oxygen-sensing genes.
Introduction

Poultry production supports the livelihoods and food security of billions of people worldwide. However, it is facing several challenges from a steep projected increase in global demand for high quality animal proteins and the need to solve the problem associated with high incidence of metabolic disorders such as woody breast (WB) myopathy, which has garnered tremendous attention the last few years. WB disorder is emerging on a global scale (Mudalal et al., 2015; Sihvo et al., 2014) and has been described as an extreme palpable stiffness of breast muscle and a myodegeneration within pectoralis major fillets (Petracci and Cavani, 2012). This phenotypic hardness of breast muscle is associated with varying degree of firmness, pale color, surface haemorrhaging and white stripes. In severe cases of WB, an eminent ridge-like bulge on caudal area of fillet is present and, in some cases, a viscous fluid cover and/or petechial multifocal lesions on the fillet surface is observed (Sihvo et al., 2014). Histologic evidence indicated multifocal degeneration and necrosis of muscle tissue with infiltration of inflammatory and fat cells (Sihvo et al., 2014).

Although the etiology of the disorder is still not known, several elegant high throughput transcriptomic and proteomics studies speculated that several potential factors including localised muscular hypoxia (Mutryn et al., 2015), oxidative stress, increased levels of intracellular calcium, and muscle fiber type switching (Soglia et al., 2016) could contribute to WB myopathy.

In addition to the animal well-being concern, the impact of WB myopathy on poultry meat quality has resulted in heavy economic loss (Kuttappan et al., 2016). In fact, severe WB has a significant negative impact on meat texture, protein content, and water-holding capacity, and thereby, on consumer acceptability and purchase (Chatterjee et al., 2016; Kuttappan et al., 2012; Mudalal et al., 2014; Tasoniero et al., 2016). There is, therefore, a critical need to define the molecular signature(s) involved in WB myopathy for subsequent development of...
mechanism-based (genetic, nutritional and/or management) strategies to reduce WB incidence. In the present study, we provide evidence that the circulatory and breast muscle oxygen homeostasis is dysregulated along with the activation of hypoxic signaling pathways in chickens with WB myopathy. We also found that quantum blue (QB), which has been shown to enhance hematological parameters in channel catfish (E., 2016), improves the expression of oxygen-sensing genes in blood and breast muscle and reduces the severity of WB disorder.

Materials and methods

Animals, diet, and experimental design

A total of 576 one-day-old male broiler chicks (Cobb 500) were weighed at day of hatch and randomly assigned to 48 floor pens in an environmentally controlled house. There were 12 birds/pen. Each pen was covered with clean pine wood shaving and equipped with separate feeders and water lines. Birds were given ad libitum access to clean water and feed for the duration of the study. The ambient temperature was gradually decreased from 32°C for days 1 to 3, 31°C for days 4 to 6, 29°C for days 7 to 10, 27°C for days 11 to 14, and 25°C thereafter. A relative humidity of ~30-40% and a 23 h light/1h dark cycles were also maintained until the end of the experiment. The environmental temperature and humidity were also continuously recorded in each pen using HOBO pro V2 data loggers (ONSET, MA).

Birds were fed one of six dietary treatments in a complete randomized design. The diets were a nutrient adequate positive control (PC) diet formulated to meet Cobb 500 nutrition requirements. Myo-inositol (MI, Sigma-Aldrich, St. Louis, MO) was added to the PC diet at 0.30% to create a second diet (PC + MI). The third diet was considered the negative control (NC) diet with a reduction of available phosphorus (avP) (Table 1), calcium and sodium by 0.15, 0.16 or 0.03%, respectively. The NC diet was then supplemented with 500, 1,000 or 2,000 phytase units (FTU)/kg to create diets four (NC+500FTU), five (NC+1,000 FTU) and six
(NC+2,000 FTU), respectively (Table 1). The phytase was Quantum Blue (AB Vista, Marlborough, UK) with an expected activity of 5,000 FTU/g.

Dead or culled birds were recorded daily and feed intake (FI, individual and cumulative) was adjusted for the day the bird died. Body weight was recorded weekly and body weight gain, Feed conversion ratio (FCR, which measures the efficiency of the bird to convert feed into meat and expressed as kg feed/kg gain), and feed efficiency (FE, which is the inverse of FCR) were determined as previously described (Washburn et al., 1975).

The present study was conducted in accordance with the recommendations in the guide for the care and use of laboratory animals of the National Institutes of Health and the protocols were approved by the University of Arkansas Animal Care and Use Committee under protocol 16084.

**WB palpation and scoring**

As previously described (Mallmann, 2017), Woody breast occurrence was estimated via live-bird palpation on a weekly basis. After slaughter process at d56, breast filets were macroscopically scored and classified to WB categories to the degree: 0, normal (NORM); 0.5-1.5, moderate (MOD) with mild hardening in the caudal S1 area; and 2-3, severe (SEV) with severe hardening and hemorrhagic lesions in the S1 region.

**Blood sampling**

For plasma samples, bloods were collected from 8 birds/treatment in vacutainer tubes with PST gel and lithium heparin and after centrifugation (1,500g; 10 min; 4°C), plasma was separated and stored at -20°C for later analyses of circulating metabolites and myo-inositol. For molecular target analysis, bloods were collected in tubes containing TRIzol LS reagent according to manufacturer’s recommendations (Life Technologies Corporation, CA). Breast muscle samples were also collected as we previously described for molecular analyses (Orlowski et
al., 2018). The remaining chickens were processed at the processing plant and carcass traits and meat quality were assessed.

**Circulating and breast muscle myo-inositol measurement**

Tissue (50-100 mg frozen weight) was homogenized in 1ml of ice-cold 5% w/v (0.83N) perchloric acid, 20mM EDTA, Na₂, in pyrex tubes with a IKA (Germany) T10 ULTRA-TURRAX® homogenizer fitted with a S10N-8G-ST probe. The homogenate was held on ice for 15 minutes and centrifuged at 15,000 x g for 10 minutes at 4 °C. The supernatant was diluted 50-fold in 18.2 mOhm cm water before analysis by HPLC-pulsed amperometry on an Antec (The Netherlands) Carbohydrate Analyser fitted with a 3mm diameter gold HyRef electrode. Chromatography of inositol followed the gradient and column conditions of Lee et al. (Lee et al., 2018). A linear calibration curve with r > 0.995 was obtained with a six point calibration curve of 0-5 µM inositol, 5 µl samples and standards were injected. Plasma inositol was measured by the same method after treatment of 1 volume of plasma with 2 volumes of ice-cold 1N perchloric acid to precipitate protein.

**Circulating metabolite measurement**

As we previously described (Nguyen et al., 2015), commercial colorimetric diagnostic kits were used to measure plasma glucose (Ciba Corning Diagnostics Corp., OH), triglycerides, cholesterol, and creatine kinase (CK, Chiron Diagnostics, Cergy Pontoise, France), lactate dehydrogenase (LDH, Bayer Healthcare, Dublin, Ireland), non-esterified fatty acids (NEFA, Wako Diagnostics, Mountain View, CA), and uric acid levels (UA, Pointe Scientific Inc, Canton, MI) with an automated spectrophotometer according to manufacturer’s recommendations. Plasma total proteins were measured using Pierce BCA protein Assay kit (ThermoFisher Scientific, Rockford, IL).

**Blood chemistry, gases, and hematology**
Blood pH, partial pressure of CO₂ (pCO₂), total CO₂ (TCO₂), partial pressure of O₂ (pO₂), bicarbonate (HCO₃⁻), base excess (BE), O₂ saturation (sO₂), sodium (Na), potassium (K), ionized calcium (iCa), glucose, hematocrit (Hct), and hemoglobin (HB) were determined using i-STAT Alinity system (SN:801128; software version JAMS 80.A.1/CLEW D36; Abaxis, Union City, CA) with the i-STAT CG8+ cartridge test (ABBT-03P77-25) according to manufacturer’s recommendation. Before use, cartridges were allowed to equilibrate to room temperature overnight. Analysis was performed at room temperature using the temperature correction function of the i-STAT Alinity system. The i-STAT system was validated in many species including mammals (Stockard et al., 2007), and birds (Martin et al., 2010; Schaal et al., 2016).

**Diffuse reflectance spectroscopic (DRS) measurement of oxygen homeostasis in breast muscle**

The optical spectroscopy instrument has been reported in detail previously (Dadgar et al., 2018). Briefly, the instrument consists of a halogen lamp (HL-2000, Ocean Optics, Dunedin, Florida), for illumination, a USB portable spectrometer (Flame, Ocean Optics), and a hand-held bifurcated fiber optic probe for light delivery and collection. The probe head that is placed in contact with tissue is 6.5 mm in diameter and consists of four illumination optical fibers (diameter = 200 μm; numerical aperture = 0.22) located at the center of the metal ferrule, and five detection fibers located at a source-detector separation distance (SDSD) of 2.25 mm away from the center (FiberTech Optica, Ontario, Canada). Diffusely reflected light from the chicken breast was collected in the spectral range of 475 to 600 nm by gently placing the probe in contact with the breast muscle. We have determined the penetration depth of this probe at SDSD of 2.25 mm to be ~ 1.8 mm, based on established methods (Nichols et al., 2012). Spectra were collected with a custom LabVIEW (National Instruments, Austin, Texas) software controlled by a foot pedal with an integration time of 100 ms. From each animal, several spectra were measured from woody breast (caudal S1 region) and three contralateral normal sites (S2, S3, and S4) and averaged optical properties were used to represent that site. Spectra were background-subtracted to eliminate ambient light. This background-subtracted light was calibrated for light throughput by
dividing it by background-subtracted reflected light intensity of an 80% reflectance standard (SRS-80-010; Labsphere, North Sutton, New Hampshire).

A lookup table (LUT) (Rajaram et al., 2008) based inverse model was used to fit the acquired optical data and extract wavelength-dependent absorption and scattering properties from tissue. To fit the model to the data, we limited scattering to follow a power-law dependence on wavelength, as described by Mourant et al. (Mourant et al., 1997), as following: 

$$\mu_s'(\lambda) = \mu_s'(\lambda_0).\left(\frac{\lambda}{\lambda_0}\right)^{-B},$$

where \(\lambda_0 = 600\) nm. We assumed only oxygenated hemoglobin (HbO\(_2\)), deoxygenated hemoglobin (dHb), and melanin to be the primary absorbers in spectral range of 475-600 nm and hence calculated \(\mu_a\) as sum of the absorbing chromophores as: 

$$\mu_a(\lambda) = [\text{Hb}]\left[\alpha\sigma_{\text{HbO}_2}(\lambda) + (1 - \alpha)\sigma_{\text{dHb}}(\lambda)\right] + [\text{Ml}]\sigma_{\text{mel}}(\lambda),$$

where [Hb] and [Ml] respectively are total hemoglobin and melanin concentrations. Alpha (\(\alpha\)) is oxygen saturation which represents the ratio of oxygenated (HbO\(_2\)) to total hemoglobin concentration [Hb]. The fixed absorption parameters, extinction coefficients of oxygenated hemoglobin (\(\sigma_{\text{HbO}_2}\)), deoxygenated hemoglobin (\(\sigma_{\text{dHb}}\)), and melanin (mel) were obtained from an online database (https://omlc.org/spectra/hemoglobin/). LUT data generation and data analysis was performed in MATLAB (Mathworks, Natick, Massachusetts).

**Reverse transcription and real-time quantitative PCR**

Breast muscle samples were collected from caudal S1 region (C) of unaffected birds and from S1 (WW, woody beast area) and S2 (WN, apparent healthy area) of WB-affected birds (Fig. 1). Total RNA was extracted from chicken blood and breast muscle samples by using TRIzol LS (for blood) and TRIzol (for muscle) reagent (Life Technologies Corporation, NY) according to manufacturer’s recommendations. RNA integrity and quality was assessed using 1% agarose gel electrophoresis and RNA concentrations and purity were determined for each sample by taking 3 Micro-Volume Plate using Synergy HT multi-mode micro plate reader (BioTek, Winooski, VT). The RNA samples were RQ1 RNase-free DNase treated (Promega, WI) and 1 \(\mu\)g RNA was reverse transcribed using qScript cDNA Synthesis Kit (Quanta Biosciences, Gaithersburg, MD). The RT reaction was performed at 42°C for 30 min followed
by an incubation at 85°C for 5 min. Real-time quantitative PCR (Applied Biosystems 7500 Real-Time PCR system) was performed using 5 µL of 10X diluted cDNA, 0.5 µM of each forward and reverse specific primer, and SYBR Green Master Mix (ThermoFisher Scientific, Rockford, IL) in a total 20 µL reaction. Oligonucleotide primers used for chicken hemoglobin subunits and oxygen-sensing genes are summarized in Table 2. The qPCR cycling conditions were 50°C for 2 min, 95°C for 10 min followed by 40 cycles of a two-step amplification program (95°C for 15 s and 58°C for 1 min). At the end of the amplification, melting curve analysis was applied using the dissociation protocol from the Sequence Detection system to exclude contamination with unspecific PCR products. The PCR products were also confirmed by 2% agarose gel and showed only one specific band of the predicted size. For negative controls, no cDNA templates were used in the qPCR and verified by the absence of gel-detected bands. Relative expressions of target genes were normalized to the expression of 18S rRNA and calculated by the 2^{-ΔΔCt} method (Schmittgen and Livak, 2008). Healthy birds and PC diet-fed birds were used as calibrators.

**Conventional and fluorescent Western blot analysis**

Conventional immunoblot for breast muscle tissues was performed as we described previously (Flees et al., 2017; Nguyen et al., 2017). The rabbit polyclonal anti-HIF-1α (# LS-C287203, LSBio, Seattle, WA), anti-phospho mTOR ser2481 (#2974), anti-mTOR (#2972), anti-phospho-PI3K P85tyr458 (#4228), and anti-PI3K (#3358) were used. Antibodies were purchased from Cell Signaling Technology (Danvers, MA). Protein loading was assessed by immunoblotting with the use of rabbit anti- GAPDH (#sc-25778, Santa Cruz Biotechnology INC., Dallas, TX). Pre-stained molecular weight marker (Precision Plus Protein Dual Color) was used as a standard (BioRad, Hercules, CA). The secondary antibodies were used (1:5000) for 1 h at room temperature. The signal was visualized by enhanced chemiluminescence (ECL plus; GE Healthcare Bio-Sciences, Buckinghamshire, UK) and captured by FluorChem M
MultiFluor System (Proteinsimple, Santa Clara, CA). Image Acquisition and Analysis were performed by AlphaView software (Version 3.4.0, 1993-2011, Proteinsimple, Santa Clara, CA).

For the fluorescent western blot analysis, 100mg breast muscle tissue was homogenized using an IKA (Germany) T10 ULTRA-TURRAX® homogenizer, fitted with a S10N-8G-ST probe, in 1mL ice cold RIPA buffer with Pierce phosphatase and protease inhibitors (Life Technology Corporation, NY). The homogenate was held on ice for 15 minutes, centrifuged at 15,000 x g for 20 minutes at 4°C and the protein content of the supernatant was quantified by a Bradford assay (Life Technology Corporation, NY). Protein (60 μg total) was resolved on a Sigma TruPAGE 4-12% gel. Samples were transferred to an iBlot 2 nitrocellulose membrane (Invitrogen, Life Technology Corporation, NY) using an iBlot 2 transfer device (Life Technology Corporation, NY). The membrane was incubated in 20 mL 5% Goat serum (Merck, NJ) in TBST for 1 hour, then incubated with 1/1,000 dilution of primary rabbit polyclonal anti-Phospho-Akt (Ser473) or Akt (pan) antibody (Cell Signalling Technology #4060 or #4691, respectively, Danvers, MA) and anti-β actin (#ab14128, Abcam Cambridge, MA) in 10 mL 5% Goat serum in TBST overnight at 4°C. Subsequently, the membrane was washed three times with TBST for 10 min then incubated with 1/10,000 secondary antibody Goat Anti-Rabbit IgG H&L (Alexa Fluor 790, #ab186697) (Abcam Cambridge, MA) in 10 mL 5% Goat serum in TBST at room temperature for 1 hour. The membrane was washed three times with TBST for 10 min and imaged on a LI-COR Odyssey infrared imaging system. The membrane was then stained and imaged for total protein using amido black. Data was analyzed using the LI-COR Image Studio software, and normalized using total protein.

**Statistical analysis**

Data were analyzed as a completely randomized one-way ANOVA using the fit model platform in JMP Pro v 14.0 (SAS Institute, Cary, NC). The model included diet. When diet
was significant, means were separated using non-orthogonal contrast statements and post-hoc Scheffe’s adjustment to reduce the likelihood of making a type-I error. Pen was considered the experimental unit for growth performance and carcass parameters. Woody breast scores were analyzed as completely randomized one-way ANOVA using the categorical platform in JMP Pro v 14.0 (SAS Institute, Cary, NC). Bird was the experimental unit and score was considered an ordinal variable. The model included diet. When diet was significant, score means between diets were separated using Pearson Chi-square. Differences between the frequency of each score within diet was also determined using Fisher’s Exact Test. Significance was accepted at $P < 0.05$. Gene and protein expression data were analyzed by Student “t” test or one-way ANOVA when appropriate. If ANOVA revealed significant effects, the means were compared by Tukey multiple range test using the Graph Pad Prism version 6.00 for Windows (Graph Pad Software, La Jolla California, USA), and differences were considered significant at $P < 0.05$.

Results

The circulatory-and breast muscle-oxygen homeostasis is dysregulated in chickens with WB myopathy

Quantification of optical properties using the DRS spectra and their LUT fits, in combination with palpation system, showed an age-dependent increase of WB incidence (data not shown) and an age-dependent increase of sO2 levels in normal breast muscle. However, the breast sO2 levels in WB-affected birds remained unchanged with age and were significantly lower compared to that of non-affected birds at 6 weeks of age (Fig. 1a), with a significant higher magnitude in the affected caudal S1 region (Fig. 1a). Further in depth analysis revealed a significant decrease of sO2 levels in S1 area of MOD and SEV WB compared to NORM breast (Fig. 1b), indicating a poor oxygenation in MOD and SEV WB. Figure 1c illustrated a low variation (less than 2-3%) between the palpation and scoring system. When using a scoring scale of 0.5, severe WB with score 3 in caudal S1 region manifested significant low sO2 levels
compared to the other scores, however S2, S3, and S4 regions did not elicit any significant
differences between all the WB scores (Fig. 1d-g).

Similarly, evaluation of hemoglobin-based parameters, showed a similar trend as for sO2
levels. As shown in Fig. 2 and 3, total hemoglobin (THB) and oxygenated hemoglobin (HBO2)
levels were significantly reduced in S1 region of MOD and SEV WB compared to NORM
breasts.

Analysis of blood gases and hematology, using iSTAT portable clinical analyzer, showed that
sO2 (P=0.07), Hct (P=0.06), and HB (P < 0.05) levels tended to be lower in chicken with WB
compared to healthy counterparts (Table 3). Together these data pointed to highly systemic
hypoxia and poorly perfused breast muscle in broilers with WB myopathy.

In support of the abovementioned data, molecular analysis showed that blood hemoglobin
subunit Mu (HBM), Zeta (HBZ), and hephaestin (HEPH) expression were significantly down
regulated, however the expression of the subunit rho of hemoglobin beta (HBBR) was
upregulated in chicken with WB compared to healthy counterparts (Fig. 4a, b). The breast
muscle HBBR, HBE, HBZ, and hypoxia-inducible factor prolyl hydroxylase 2 (PHD2 also
known as EGLN1) mRNA abundances were significantly down regulated in WB compared to
normal birds (Fig. 4c, d). However, MB gene expression was significantly upregulated in the
breast of WB-affected compared to non-affected birds (Fig. 4d).

**HIF-1α and its upstream mediators are activated in chickens with WB myopathy**

As illustrated in figure 5a & b, the expression of HIF-1α at mRNA and protein levels was
significantly induced in breasts (affected caudal area, WW and apparent healthy area, WN) of
broilers with WB myopathy compared to their healthy counterparts, indicating a hypoxic status.

The phosphorylated levels of AKT at Ser473 site, mTOR at Ser2481 site, and PI3K P85 at
Tyr458 site, as well as their mRNA levels were significantly increased in breasts (affected
caudal area, WW and apparent healthy area, WN) of broilers with WB myopathy compared to their healthy counterparts (Fig. 5c-h).

**Plasma myo-inositol and metabolite levels and breast muscle mineral profiles in WB-affected and unaffected birds**

Plasma glucose, cholesterol, triglyceride, total proteins, CK, NEFA, and myo-inositol did not differ between WB-affected and unaffected birds (Table 4). The concentrations of Ca, Na, and Zn were significantly higher in the breast muscle of WB-affected broilers compared to their healthy counterparts (Table 4). However, the levels of the elements K, Mg, P, and S were significantly lower in WB-affected compared to unaffected group (Table 4). The levels of Al, Cu, Fe, and Mn remain unchanged between the two groups (Table 4).

**Quantum blue reduces WB severity via modulation of oxygen-sensing genes**

In attempt to identify a nutritional strategy to reduce WB incidence, we used different increasing doses of QB. Birds were maintained under standard environmental conditions (Fig. 6a) and QB was supplemented at 500; 1,000; and 2,000 FTU/kg diet for 56 days. As shown in Figure 6b-f and as expected, negative control birds (Ca- and P-deficient diet) decreased their individual and cumulative feed intake, and in turn, showed lower average body weight and body weight gain compared to standard and positive control diet as well as to QB-supplemented diets. Although the activity rate recovery of QB was as expected (Table 5), QB did not have any significant effect on FCR and FE (Table 6). However, QB supplementation quadratically increased ($P < 0.05$) hot and cold carcass weight, breast meat yield and wing and leg yield (Table 7). Although the incidence of WB myopathy did not differ between the positive control and QB-fed groups, high dose (1,000 and 2,000 FTU) of QB significantly reduced the severity of WB by ~5% compared to the positive control (Fig. 7).

At molecular levels, QB supplementation reverses the expression profile of oxygen homeostasis-related genes; i.e. significant down regulation of HBBR (at 2,000 FTU) and...
upregulation of HBM, HBZ, and HEPH (all doses of QB) in blood (Fig. 8a-d), as well as a significant upregulation of HBA1, HBBR, HBE, HBZ, and EGLN1 in breast muscle compared to the positive control with the doses 1,000 and 2,000 FTU are the most efficient (Fig. 9 a-f).

At systemic levels, QB supplementation did not elicit any change to the plasma metabolite levels in healthy chickens, except a reduction of CK concentrations with QB superdose (2,000 FTU). At tissue levels, QB-enriched diets reduce Cu and Fe levels. However only 1,000 FTU of QB reduces Ca levels in breast muscle compared to the PC-fed group (Table 8). QB supplementation slightly increase myo-inositol levels in the breast muscle of unaffected chickens (Table 8).

**Discussion**

The signaling pathways and molecular mechanisms involved in WB myopathy, which is an emerging challenge to the poultry industry worldwide, remain largely undefined. Here, using a combination of the diffuse reflectance spectroscopy (DRS) technique and the portable clinical analyzer iSTAT system, we showed a systemic hypoxic status and a poorly oxygenated breast muscle in broilers with WB myopathy compared to their healthy counterparts.

The DRS has been used in several studies to measure tissue scattering, total hemoglobin content, and vascular oxygenation (Dadgar et al., 2018; Dhar et al., 2012; Vishwanath et al., 2009). The DRS-based measurement of broiler breast muscle oxygenation status can provide a non-destructive and non-invasive tool for an early detection of WB-susceptible birds and, thereby, could aid in the selection of appropriate prevention/intervention strategy.

Similarly, the iSTAT system is gaining popularity in biological research for blood analysis and has been validated on a wide range of species including birds (Schaal et al., 2016), reptiles (Harms et al., 2003), fish (Harter et al., 2014), and mammals (Sediame et al., 1999; Stockard et al., 2007). Although the specific type of hypoxia is not known at this time point, both DRS- and iSTAT-based measurement suggested a complex hypoxia. Indeed, the low oxygen levels
in the circulation and in breast muscle of WB birds indicates both a circulatory and a hypoxemic hypoxia (anoxia) (Fedorova, 1964). The low levels of hemoglobin in the circulation indicates a potential anemic hypoxia (Cain and Chapler, 1988) which results in a reduced ability of the blood to carry oxygen and, thereby, a diminished supply of oxygen to the breast muscle. A metabolic hypoxia, which might due to high demand for oxygen by the breast muscle that exceed the supply/delivery, is not ruled out (Chappell et al., 2019).

Whatever the type of hypoxia, it is evident that circulatory and breast muscle oxygen homeostasis are altered in birds with WB myopathy. This is supported by the dysregulation of oxygen transport-related molecules including hemoglobin subunits (mu, HBM and zeta, HBZ) in red blood cells, and myoglobin (MB), hemoglobin beta (subunit rho HBBR, and epsilon HBE), and HBZ in breast muscle of WB-affected birds compared to their healthy counterparts.

The major oxygen-transport proteins in vertebrate blood are hemoglobins and hemerythrins with iron as the prosthetic group. These metallated and multi-subunit proteins are responsible primarily for the sensing, transport, and/or storage of oxygen (Terwilliger, 1998). Until recently, it has been thought that vertebrate hemoglobin is expressed only in erythrocytes. Here we found that hemoglobin subunits are expressed not only in red blood cells but also in breast muscle corroborating previous studies that have reported hemoglobin expression in a wide variety of non-erythroid cells and tissues including neurons (Biagioli et al., 2009; Ohyagi et al., 1994; Schelshorn et al., 2009), macrophage (Liu et al., 1999), eye lens (Wride et al., 2003), and breast cancer cells (Gorr et al., 2011). The upregulated expression of HBBR in blood, MB in breast, and down regulation of the other subunits (HBM and HBZ) in both blood and breast muscle of WB birds indicated that these subunits have different oxygen affinities or response to allosteric modifiers (Terwilliger, 1998). Together, the low oxygen levels combined with the dysregulation of oxygen-sensing genes indicate a hypoxic status in the breast muscle of WB-affected birds (Cadiz et al., 2017; Gorr et al., 2004; Grek et al., 2011; Xia et al., 2016).
To gain further insight into the etiology of this myopathy and its underlying molecular mechanism, we assess the hypoxia signaling interactive pathway. The upregulation of HIF-1α and down regulation of PHD2 (also known as EGLN1) expression in the breast muscle of WB-affected birds supported the DRS and iSTAT data and confirmed the hypoxic status. Central to the molecular mechanisms underlying oxygen homeostasis are HIF-1α and HIF-2α that function as master regulators of the adaptive response to hypoxia (Nakazawa et al., 2016). HIFs form a heterodimer consisting of a constitutively expressed HIF-1β subunit and oxygen-regulated α subunits (HIF-1α or HIF-2α) (Keith et al., 2011; Majmundar et al., 2010). A HIF-3α has been also described (Ema et al., 1997). Under normoxic conditions, HIF α-subunits are hydroxylated by prolyl hydroxylases (PHD also known as HIF-1 prolyl hydroxylases HPH or EGLN1) and targeted for proteasomal degradation by the Von Hippel–Lindau disease tumour suppressor protein (pVHL), a component of the E3 ubiquitin ligase complex (Lee et al., 2016). These PHDs are 2-OG-dependent dioxygenase enzymes which require oxygen for their hydroxylation action, and hence they are inactivated when the oxygen level is insufficient, and in turn, enhances the activity of HIF by stabilizing its α subunit (Epstein et al., 2001).

In agreement with previous studies (Gingras et al., 2001; Jiang et al., 2001), the activation of phosphatidylinositol-4,5-bisphosphate-3-kinase (PI3K)- protein kinase B (PKB or AKT)-mechanistic target of rapamycin (mTOR) pathway in our experimental conditions indicates that this pathway might upregulate HIF-1α protein translation. PI3K regulates protein syntheses through its target AKT and downstream component mTOR. mTOR mediates its action via phosphorylation of the eukaryotic translation initiation factor 4E(eIF-4E) binding protein (4E-BP1) disrupting the integrity of these two components, which is essential for inhibiting cap-dependent mRNA translation, resulting in enhanced HIF-1α protein translation (Treins et al., 2002). Land and Tee (Land and Tee, 2007) have shown that Rheb-specific activation of mTOR
enhanced the transcriptional activity of HIF-1α during hypoxia. It has also been reported that mTOR shuttles between the cytoplasm and the nucleus and that this cytoplasmic-nuclear interchange of mTOR is necessary for the mTOR-dependent phosphorylation of S6K1p70 S6 kinase (S6K) which, in turn, induces HIF-1α protein translation (Kim et al., 2014; Kim and Chen, 2000).

Intreguigingly, we found that hephaestin (HEPH) gene expression was down regulated in the circulation but not in breast muscle of WB birds. Currently, HEPH is well known to be involved in the intestinal metabolism of iron and possibly copper (Chen et al., 2006). It is a transmembrane copper-dependent ferroxidase responsible for transporting dietary iron from intestinal enterocytes into the circulation system and mediates iron efflux in cooperation with the basolateral iron transporter, ferroportin 1 (FPN1) which is slightly upregulated in blood of WB birds. However, copper and iron levels in the breast muscle did not differ between WB-affected and unaffected birds. This suggests that HEPH may have other roles in the circulation that need to be defined. As it belongs to the same family as ceruloplasmin, it is possible that HEPH is involved in copper/iron detoxification. Interestingly and similar to dog hereditary muscle dystrophy (Mehta et al., 1989), we found a differential mineral element profile; increased levels of Ca, Na, and Zn, and decreased levels of K, Mg, P, and S in beast muscle of WB birds. Although a mechanistic interaction between minerals and WB myopathy is lacking, our data suggest that WB might be associated with mineral overload/deficiency. It has been shown that hypoxia increases intracellular Zn levels (Bernal et al., 2008) and intracellular Zn overload has been reported to alter skeletal muscle contractility (Bernal et al., 2011; Isaacson and Sandow, 1963). Hypoxia was also found to increase basal Ca and Na concentrations, and reduce K and P levels (Shi et al., 2014; Weiss et al., 1989; Yadav et al., 2013). It is clear from several lines of evidence that defect in intracellular element (Ca, Na, P, K, etc.) homeostasis is a hallmark of muscular dystrophies (Altamirano et al., 2012; Bkaily and Jacques, 2017; Mijares...
et al., 2014; Saito et al., 2017; Weber et al., 2012). Although further in-depth mechanistic
studies are warranted, it is possible that hypoxia-induced intracellular mineral unbalance alter
muscle ATP concentration and energy utilization, which activates the master energy sensor
AMPK (data not shown) and, in turn, leads to reactive oxygen species (ROS) production,
inflammation, and muscle fiber degeneration (Guo et al., 2014; Irrcher et al., 2009).

Because QB has been reported to improve hematological parameters (number of red blood
cells, hemoglobin, and hematocrit) in channel catfish (E., 2016; Ferreira and Aurélio Lopes
Della Flora, 2017), we hypothesized that QB might reduce WB incidence. Although the total
incidence of WB did not differ between all groups, QB reduces the severity of WB by ~5%
compared to the control group. Ameliorating WB severity is very critical and beneficial not
only for the animal well-being but also for the poultry industry and the consumer because the
severity of the myopathy can adversely affect consumer perception and acceptance of raw cut
up parts and/or quality for further processed meat products (Kuttappan et al., 2017), resulting
in significant economic loss to the industry. The effect of QB seemed to be mediated via the
increased expression of oxygen-sensing genes leading to enhanced oxygenation in both blood
and breast muscle. QB is a phosphatase enzyme that catalyzes the hydrolysis of phytate,
thereby liberating utilizable inorganic phosphate and myo-inositol. Myo-inositol has been
shown to increase oxygen pressure and antagonize the hypoxic setting (Derbal-Wolfrom et al.,
2013). Although the mode of action of QB merits further investigations, it is possible that QB
also improve mineral and nutrient uptake by destroying phytate and its other downstream
hydrolysis products.

In conclusion, this is the first mechanistic evidence, to our knowledge, showing that WB
myopathy is associated with systemic and local breast muscle hypoxia, and we identified a
potential nutritional strategy to reduce its severity.

Declaration of interest
The authors have nothing to disclose

**Author contributions**

SD (Sami Dridi) conceived and designed the study. EG and JF conducted the experiments, determined gene and protein expression, and analysed the data. SD (Sina Dadgar) and NR, measured the oxygen levels using the DRS technique. BM and SO determine the WB incidence by palpation and scoring. CL, HW, CB measured the myo-inositol and determined AKT expression by fluorescent western blot. CW provided the QB. SD wrote the paper with a critical review by CW, MK, NR, and SR.

**Funding**

This study was supported by a grant from ABV (to Sami Dridi). ABV had no role in conducting the research, generating the data, interpreting the results or writing the manuscript. Hayley Whitfield, Caroline Laurendon, and Charles Brearley were supported by a grant from the Biotechnology and Biological Sciences Research Council UK.

**Figure legends**

**Figure 1.** Dysregulation of oxygen levels in the breast muscle of WB-affected broilers. DRS measurement shows a significant lower sO2 levels in WB-affected birds compared to their healthy counterparts at 6 weeks of age, with higher magnitude in caudal S1 region (a). Decrease of oxygen levels in MOD and SEV woody breast (b). Correlation between palpation and scoring system (c). Decrease of oxygen levels in SEV WB with score 3 in broiler breast muscle (d-g). Data are presented as mean ± SEM (n=50/group). * and different letters indicate significant difference at $P < 0.05$. (+) WB-affected birds, (-) non-affected birds.

**Figure 2.** Dysregulation of total hemoglobin (THB) levels in the breast muscle of WB-affected broilers. DRS measurement shows a significant decrease of THB levels in caudal S1 region of breast muscle (a). Decrease of THB levels in MOD and SEV woody breast (b). Decrease of THB levels in WB with score 0.5- in broiler breast muscle in region S1, S2, S3, and S4 (c-f). Data are presented as mean ± SEM (n=50/group). * and different letters indicate significant difference at $P < 0.05$. (+) WB-affected birds, (-) non-affected birds.

**Figure 3.** Dysregulation of oxygenated hemoglobin (HBO2) levels in the breast muscle of WB-affected broilers. DRS measurement shows a significant decrease of HBO2 levels in caudal S1 region of breast muscle (a). Decrease of HBO2 levels in MOD and SEV woody breast (b). Decrease of HBO2 levels in WB with score 0.5 to 3 in broiler breast muscle in region S1, S2, S3, and S4 (c-f). Data are presented as mean ± SEM (n=50/group). * and different letters indicate significant difference at $P < 0.05$. (+) WB-affected birds, (-) non-affected birds.

**Figure 4.** Dysregulation of oxygen-sensing genes in WB-affected broilers. Oxygen-sensing genes are expressed in broiler blood (a), and breast muscle (c). Dysregulation of oxygen-sensing genes in blood (b) and breast muscle of WB-affected birds (d). mRNA abundances were determined by qPCR and analyzed by $2^{-\Delta \Delta Ct}$ method. Data are presented as mean ± SEM (n=8/group). * indicates significant difference at $P < 0.05$. 

26
Figure 5. Activation of hypoxia signaling pathway in breast muscle of WB-affected birds.
Upregulation of HIF-1α mRNA and protein in WB-affected birds (a, b). Upregulation of HIF-1α upstream mediators including AKT (c-e), and PI3K-mTOR (f-h). Protein expression was measured by conventional and fluorescent western blot, and relative gene expression was determined by qPCR. Data are presented as mean ± SEM (n=8/group). Different letters indicate significant difference at P < 0.05. Western blot image is a representative of 3 replicates.

Figure 6. Effect of QB-enriched diets on broiler growth performances. (a) Environmental condition (RH and T°) of the barn. QB did not affect individual and cumulative feed intake (b, c), and average BW and BWG (d-f). Data are presented as mean ± SEM (n=96 birds/group). * indicates significant difference at P < 0.05.

Figure 7. QB-enriched diets reduces the severity of WB incidence. At day 56 and After slaughter process, breast filets were macroscopically scored and classified to WB categories to normal (NORM, score 0), moderate (MOD, score 0.5-1.5), and severe (SEV, score 2-3).

Figure 8. QB-enriched diets modulate the expression of oxygen-sensing genes in broiler blood. Relative gene expression was determined by qPCR and analyzed by 2^-ΔΔCt method using PC group as a calibrator. Data are presented as mean ± SEM (n=8 birds/group). * indicates significant difference at P < 0.05 compared to PC group.

Figure 9. QB-enriched diets modulate the expression of oxygen-sensing genes in broiler breast muscle. Relative gene expression was determined by qPCR and analyzed by 2^-ΔΔCt method using PC group as a calibrator. Data are presented as mean ± SEM (n=8 birds/group). * indicates significant difference at P < 0.05 compared to PC group.
### Table 1. Ingredient and nutrient composition of the experimental diets, as-is basis

| Ingredient, %          | Starter phase | Grower phase | Finisher phase |
|------------------------|---------------|--------------|----------------|

| S | 1949±27 | 1601±29* |
| Zn | 6.4±0.3 | 12.1±0.5* |

¹Means represent the average response of 8 replicate pens/treatment and 5-8 birds/pen. *P < 0.05.

²CK, creatine kinase; Al, aluminium; Ca, calcium; Cu, copper; Fe, iron; K, potassium; Mg, magnesium; Mn, manganese; Na, sodium; P, phosphorus; S, sulfur; Zn, zinc
Table 5. Phytase activity (FTU/kg) recovered in the experimental diets

| Experimental diet          | Starter phase | Grower phase | Finisher phase |
|----------------------------|---------------|--------------|----------------|
| Positive control (PC)      | < 50          | < 50         | < 50           |
| PC + 0.30% inositol        | < 50          | < 50         | < 50           |
| Negative control (NC)      | < 50          | < 50         | < 50           |
| NC + 500 FTU               | 385           | 840          | 550            |
| NC + 1,000 FTU             | 834           | 1,480        | 1,310          |
| NC + 2,000 FTU             | 1,850         | 2,490        | 1,950          |

1 The phytase used was Quantum Blue (AB Vista, Marlborough, UK) with an expected activity of 5,000 FTU/g.
Table 6. Effects of QB on growth performances

| Diet                                | FCR    | FE     | Mortality (%) |
|-------------------------------------|--------|--------|---------------|
| Positive control (PC)               | 1.7106 | 0.5845 | 7.3           |
| PC + myo-inositol (MI)              | 1.6914 | 0.5912 | 2.6           |
| Negative control (NC)               | 1.7786 | 0.5622 | 1.4           |
| NC + 500 FTU/kg phytase             | 1.6976 | 0.5890 | 3.1           |
| NC + 1,000 FTU/kg phytase          | 1.7247 | 0.5797 | 4             |
| NC + 2,000 FTU/kg phytase          | 1.7005 | 0.5880 | 7.3           |

1 Means represent the average response of 8 replicate pens/treatment and 20 birds/pen. FCR, feed conversion ratio; FE, feed efficiency.
Table 7. Live weight and carcass and cut up weight of broilers fed myo-inositol or phytase from hatch to 46-days post-hatch

| Diet                                      | Live weight, g | Hot carcass weight, g | Cold carcass weight, g | Breast meat weight, g | Wing weight, g | Tender weight, g | Leg weight, g | Rack, weight, g |
|-------------------------------------------|----------------|-----------------------|------------------------|----------------------|----------------|-----------------|---------------|----------------|
