ABSTRACT

Objectives The objective of this study is to investigate whether papers reporting research on Chinese transplant recipients comply with international professional standards aimed at excluding publication of research that: (1) involves any biological material from executed prisoners; (2) lacks Institutional Review Board (IRB) approval and (3) lacks consent of donors.

Design Scoping review based on Arksey and O’Malleys methodological framework.

Data sources Medline, Scopus and Embase were searched from January 2000 to April 2017.

Eligibility criteria We included research papers published in peer-reviewed English-language journals reporting on outcomes of research involving recipients of transplanted hearts, livers or lungs in mainland China.

Data extraction and synthesis Data were extracted by individual authors working independently following training and benchmarking. Descriptive statistics were compiled using Excel.

Results 445 included studies reported on outcomes of 85,477 transplants. 412 (92.5%) failed to report whether or not organs were sourced from executed prisoners; and 439 (99%) failed to report that organ sources gave consent for transplantation. In contrast, 324 (73%) reported approval from an IRB. Of the papers claiming that no prisoners’ organs were involved in the transplants, 19 of them involved 2688 transplants that took place prior to 2010, when there was no volunteer donor programme in China.

Discussion The transplant research community has failed to implement ethical standards banning publication of research using material from executed prisoners. As a result, a large body of unethical research now exists, raising issues of complicity and moral hazard to the extent that the transplant community uses and benefits from the results of this research. We call for retraction of this literature pending investigation of individual papers.

INTRODUCTION

The transplantation of organs procured from executed prisoners is widely condemned by bodies including WHO, 1 the World Medical Association, 2 The Transplantation Society (TTS), 3 Amnesty International and the Declaration of Istanbul. 4, 5 This condemnation extends to undertaking research and presenting results that involve the use of organs obtained from executed prisoners.6 In 2006, TTS explicitly stated that it would not accept conference papers based on research involving organs sourced from executed prisoners. 7 The 2006 policy statement by TTS was followed by calls for a boycott on accepting conference papers or publishing journal articles based on research involving organs from executed prisoners. 8–10 Some journals explicitly adopted this ban as policy (Journal of Clinical Investigation, 11 American Journal of Transplantation and the Journal of Heart and Lung Transplantation). 9

Strengths and limitations of this study

► The main strengths of this study lie in its originality and in the use of robust scoping review methods, giving confidence that the results are reliable.
► The study provides evidence that a large number of published papers violate ethical standards by including data on transplants involving organs procured from prisoners.
► The data set was limited by exclusion of publications in languages other than English, or published in Chinese journals, regardless of the language of publication.
► The data in the included studies were imprecise regarding organ sources.
► The total number of participants (and hence number of transplants) in the included studies is inflated by multiple publication of the same and overlapping research cohorts.

Together, these statements by international bodies, professional societies, academics and journals constitute explicit ethical standards prohibiting the publication or presentation of research involving organs sourced from executed prisoners. These standards are primarily directed towards peer-reviewers, editors and publishers. However, these standards lack regulatory force; there are no sanctions for breaches, and to date there has been no audit investigating compliance.

This study is the first attempt to track the progress of the transplant community in meeting this ethical injunction to avoid publication of research based on organs sourced from executed prisoners.

**BACKGROUND**

The prohibition against the use of executed prisoners’ organs is explicitly directed towards China, which is one of the few countries where the use of prisoners’ organs has been government-sanctioned. In 2001, a Chinese official dismissed as ‘sensational lies’ reports of organ harvesting from executed prisoners, claiming that the majority of organs was voluntary donations. This rhetoric changed in 2006 when Chinese officials first openly acknowledged that the majority of transplanted organs were sourced from executed prisoners. In 2007, China claimed it would reduce reliance on executed prisoners, but in a 2015 interview, Huang Jiefu, China’s most senior transplant official, stated that there had been just 120 cases of volunteer donors up to 2009. In 2014, Huang committed China to using only organs from volunteer donors from 1 January 2015. However, the use of prisoners’ organs remains technically legal today in China if ‘consent’ is obtained, and in 2017 Chinese officials admitted that it is not possible to verify that all organ harvesting from prisoners has ceased.

Use of organs from executed prisoners is widely condemned because the coercive situation of being on death row undermines the possibility of ethically valid consent, or consent may not be sought at all. Publication in international, peer-reviewed journals is a marker of academic success and professional credentials. Large, well-rendered results are more likely to attract international attention, media attention and a research career. Peer reviewers, editors and publishers are committed to the integrity and accountability of published research. Peer review is the world’s most effective way to express condemnation of unethical research practices, leading to formal TTS policy changes. Organ procurement practices, leading to formal TTS policy and recommendations for banning unethical research as described above. Publication in international, peer-reviewed journals is a marker of academic success and international acceptance. Imposing a ban sends a strong message of disapproval to researchers whose projects involve transplants of organs sourced from executed prisoners.

The current approach to this issue taken by TTS and some journals is incremental rather than absolutist. An ‘absolutist’ approach would ban publication of all Chinese transplant data until there is compelling positive evidence that the use of executed prisoners’ organs has ceased. This would require free and full on-site inspections of Chinese transplant hospitals, including unfettered access to hospital information systems. China has not agreed to such inspections and no international or professional body has assumed responsibility for pursuing this issue. Instead, the professions’ preferred incremental approach requires assessment of Chinese studies for ethical acceptability prior to publication, with exclusion of any that include data from executed prisoners. The incremental policy therefore requires peer-reviewers and journal editors to ask consistently whether the research: (1) involved any biological material sourced from executed prisoners; (2) received Institutional Review Board (IRB) (Research Ethics Committee) approval and (3) required consent of donors. For transparency purposes, this information should be included in the final publication. Transparency contributes to a culture of accountability and ensures that readers are not unthinkingly absorbing and using unethically obtained data. The burden of proof should rest with authors/researchers to supply evidence of consent to donation, and approval by an IRB, and attest that their study does not use material derived from executed prisoners.

In this study, we investigated the extent to which journals have complied with these ethical standards by: (1) publishing only research using organs from volunteer donors; (2) requiring a statement of IRB approval and (3) providing a statement that consent was obtained from donors. As noted above, ‘consent’ obtained from executed prisoners does not meet international ethical standards.

**METHODS**

This research used scoping review methodology. Scoping reviews can be used to map an area of research, summarise existing evidence or identify gaps in the literature. Unlike systematic reviews, scoping reviews usually do not assess the quality of the included studies. This review followed the five steps articulated by Arksey and O’Malle to ensure rigour, transparency and facilitate replication (table 1).

The research question was identified and refined through discussion among the authors and expert colleagues. The final version was: ‘To what extent do papers reporting research on Chinese transplant recipients: identify the sources of organs; state whether sources

| Framework stage | Description |
|-----------------|-------------|
| 1               | Identifying the research question |
| 2               | Identifying relevant studies |
| 3               | Study selection |
| 4               | Charting the data |
| 5               | Collating, summarising and reporting the results |
were living or deceased; and comply with ethical requirements for human research and organ donation as per international guidelines and professional standards?"}

**Search strategy**

Relevant studies in English-language journals were identified through searching online databases. The electronic search strategies were developed, tested and refined with the assistance of an expert librarian. The search aimed to identify full-text papers published in English in peer-reviewed journals by authors based at Chinese institutions that reported on research involving recipients of solid organ transplants. The search strategies for Medline, Scopus and Embase were described in online supplementary file 1. The inclusionary criteria were organ transplantation/transplant (title, abstract) and China (institution/affiliation). The exclusionary criteria were stem cells (title, abstract); mice (title, abstract); living donors (title, abstract); case reports/letters/editorials (document type). The searches were limited to English language and humans, and the years were 2000–date of search. The start date of 2000 was selected as this is when numbers of transplantsations and associated research papers rapidly increased in China.

Medline, Scopus and Embase were searched on 5 April 2017 by WR, BB and RC-W. All relevant searches were downloaded into an EndNote library by WR. Duplicates were removed by EndNote filter. We did not identify further papers from other sources or search the references of included papers as we aimed to capture papers that are readily available through mainstream databases, and this was a scoping rather than systematic review. We recognised that our search strategy might potentially miss some papers published in difficult to find journals as well as those published in languages other than English, with a potential reduction in sensitivity. However, we do not think that papers omitted as a result of this strategy undermine the reliability of the findings. Rather, these omissions may make our estimate of the magnitude of any ethical breaches of publication standards conservative, based on the assumption that ethical compliance is likely to be higher in international journals published in English compared with journals published in China whether in Chinese or English language.

The title and abstracts remaining after removal of duplicates were screened for obvious exclusionary factors, with each author screening an equal number. All authors were trained in the use of the exclusionary criteria by screening the same 100 abstracts and titles. At the end of the pilot process, the exclusionary criteria were refined following discussion. The final exclusionary criteria for title and abstract screening were:

- transplants other than solid organs;
- transplants not occurring in mainland China;
- clinical case reports and/or incidental inclusion of data from Chinese transplant recipients;
- meta-analyses and systematic reviews;
- animal research;
- English-language journals published in China.

Articles which could not be eliminated by title and abstract were reviewed as full-text articles to determine eligibility. Prior to full-text review, five of the authors (WR, MPR, RC, BB, RC-W) undertook further training and benchmarking in use of the exclusionary criteria on full-text papers. This involved all five screening the same 20 papers, followed by discussion. The exclusionary criteria were finalised after this process (box 1), and four authors (RC, WR, MPR, BB) assessed full-text articles for eligibility.

**Box 1 Exclusion criteria for full-text review of papers**

- ‘Animal research’—exclude any non-human research.
- ‘Chinese journal’—exclude any papers published in (English language) journals published in China, on the assumption of low compliance with Western ethical standards.
- ‘Case report’—exclude papers reporting on clinical case reports.
- ‘Incidental inclusion’—exclude papers where transplant recipients are incidentally included as research participants.
- ‘Kidneys’—exclude any papers reporting data from kidney transplant recipients due to ambiguity of source (living or deceased).
- ‘Living donors’—exclude papers where all the transplanted organs were procured from living donors, including split livers from living donors.
- ‘Not China’—exclude any papers where the transplants took place outside mainland China.
- ‘Not reviewed’—exclude any non-peer-reviewed publications (including commentaries, letter to editors, etc).
- ‘Other organs’—exclude other tissue or organs, that is, not livers, hearts or lungs.
- ‘Other’—state reason.
- ‘Review paper’—exclude review papers (meta-analysis, systematic reviews, etc).

---

**Figure 1** Preferred Reporting Items for Systematic Reviews and Meta-Analyses flow chart detailing search strategy.
The reasons for exclusion were recorded, but where more than one reason was present, only the first reason noted by the data extractor was recorded. Papers reporting on recipients of kidney transplants were excluded at the full-text review stage after a trial of 200 full-text analyses. In this sample, 40% of kidney papers failed to report whether organ sources were living or deceased. As a key question in our research concerned procurement of organs from executed prisoners, we did not want to include a potentially large number of papers in which it was unclear whether or not organs were procured from living donors.

The same four authors who determined eligibility of full-text papers also extracted data from these papers onto pretested forms (see online supplementary file 2 for details extracted). Any details that could not be extracted with certainty were discussed by the group of authors to reach a consensus. No data extraction outcomes were unable to be resolved using this method. Data from 10% of included papers were checked by a second author. This process is summarised in a Preferred Reporting Items for Systematic Reviews and Meta-Analyses diagram (figure 1).

**RESULTS**

The searches identified 6723 records, leaving 4168 after duplicates were removed. After screening of abstracts and titles, 2489 records were excluded. One thousand six hundred seventy-nine full-text articles were screened for eligibility. One thousand two hundred twenty-nine were excluded (table 2). Four hundred forty-five papers were included in the final data set (see online supplementary file 3), and five papers were unavailable.

The main results are summarised in table 3. See online supplementary file 4 for a full table of results.

Overall, 324 (73%) of the 445 papers included a statement regarding approval from an institutional or regional ethics committee. Most of these statements were of a general type such as: ‘The study protocol was conducted in accordance with the standards of the Declaration of Helsinki and current ethical guidelines’; ‘All protocols were approved by the ethics committee of the institution before the study began, and the protocols conformed to the ethical guidelines of the 1975 Helsinki Declaration’; and ‘The present study was approved by the ethics committee of Qingdao University (Qingdao, China)’. Few contained an IRB reference number or the date approval was granted. The majority of these statements reported that research participants (who were the transplant recipients) had given their informed consent.

The graph in figure 2 shows ethics approvals by year. These increased substantially after 2006, which was the year that TTS published its policy banning conference papers based on data from executed prisoners.

### Table 2 Reasons for exclusions of full-text papers (n=1229)

| Reason            | Number |
|-------------------|--------|
| Animal research   | 12     |
| Chinese journal   | 96     |
| Case report       | 3      |
| Incidental inclusion | 14   |
| Kidneys           | 637    |
| Living donors     | 7      |
| Not China         | 380    |
| Not reviewed      | 1      |
| Other organs      | 2      |
| Other             | 49     |
| Review paper      | 28     |

### Table 3 Results summary table

| Variable                                         | Number (%  )         |
|--------------------------------------------------|----------------------|
| Total number of included papers                  | 445 (100)            |
| Total number of transplants reported             | 85 477               |
| Median number of transplants per paper (range)    | 72 (1–20524)         |
| Number of papers that explicitly stated organs (hearts, livers, lungs) were from deceased sources | 173 (39)           |
| Number of papers reporting research ethics approval | 324 (73)           |
| Number of papers with any information on the identity of the sources of organs | 63 (14)            |
| Number of papers with explicit statement that no organs from prisoners were used | 33 (7)              |
| Number of papers that reported consent for donation | 6 (1)               |
| Number of papers with any statement about the diagnosis of death in sources (after brain death, after cardiac death) | 64 (14)           |

**Patient and public involvement**

There was no patient or public involvement in this scoping review of published literature.
Only 63 papers (14%; see online supplementary file 5) included any information about the source of the organs (ie, whether or not the organs came from executed prisoners or volunteers, or if consent was given). This category of organ sources (donor identity) was interpreted inclusively. For example, papers reporting that sources gave informed consent were included here even if there was no explicit statement that the sources were not prisoners. Under Chinese policy, prisoners are permitted to make allegedly voluntary donations, which is in violation of TTS policy.\(^{33}\) The presence or absence of statements identifying organ sources by year is in figure 3. Only one paper published prior to 2007 included any information about identity of sources.\(^{34}\)

Among the 63 papers that provided any information about the sources of organs, 33 (7.4% of all included studies) stated explicitly that no organs from executed prisoners were used in the transplantations.\(^{30,31,34-62}\) Five of these also stated explicitly that organs were sourced from volunteers.\(^{35,39,46,48,61}\) Three of the 33 reported that informed consent was obtained from sources or their families, and these three papers also included a statement about ethics review.\(^{30,47,61}\) That is, <1% of included studies contain all three pieces of information mandated by TTS.\(^{33}\)

However, the claims that organs were not procured from prisoners cannot be true in many of these 33 papers. According to Chinese reports, there were only 120 voluntary donors in the whole of China up until 2009,\(^{10}\) and donation numbers were low during the nascent volunteer donor programme from 2010 to 2014 (table 4).\(^{66}\)

Yet 19 of the 33 papers claiming that organs were not procured from executed prisoners reported on 2688 transplants that took place prior to 2010.\(^{34,35,36-38,53,54,61,63,65-76}\) One of these did not date the transplants but was published in 2010 reporting on grafts that had been stable for at least 2 years, indicating that the transplants had taken place prior to 2010.\(^{37}\) Eight of the 33 papers report on 1212 transplants that occurred both before and after 2010\(^{30,31,35,39,43,52,59,62}\) and 6 of them report on 1556 transplants that took place during the period 2010–2014 during the pilot volunteer scheme.\(^{17,42,53-57,60,64}\)

Turning to the 30 papers without explicit statement about prisoners, in 14 of these, statements indicated that organs were procured from volunteers, without specifying whether or not prisoners were excluded as volunteers.\(^{78-91}\) Three of the 14 stated that informed consent was provided by donors or their families.\(^{98-107}\)

Six papers reported that sources gave informed consent for donation, but did not record whether or not these were volunteers or prisoners.\(^{92-97}\)

There were 10 papers that contained information implying that donations were from voluntary, non-prisoner sources, without explicitly stating this, or that consent was provided.\(^{98-107}\) The statements from these papers are in box 2.

These statements do not necessarily preclude inclusion of organs procured from executed prisoners. For example, two papers refer to legal donation,\(^{100,102}\) which might include organs from executed prisoners. Two papers refer to donors dying from severe injurys or in accidents. While these are potentially legitimate causes of death for organ donors, it is possible

### Box 2 Text from papers reported in ‘Other’ category of donor ID information

- All the donors were from traffic accidents or cerebral bleeding coma.\(^{98}\)
- No organ trafficking involved.\(^{99}\)
- Organ donation was conducted legally, following local regulations.\(^{100}\)
- Five donors were brain dead due to car accident, their respiration was maintained by mechanical ventilation and haemodynamics was stabilised by minimum doses of catecholamine.\(^{101}\)
- The deceased donor livers were obtained through both social and legal donation.\(^{102}\)
- The donation procedure followed the donation after cardiac death (DCD) guidelines of China.\(^{103}\)
- Severe injuries and traffic accidents were the main reasons for DCD.\(^{104}\)
- Normal control hearts came from autopsies or donors with no history of heart disease who died in accidents.\(^{105}\)
- All the DBCD grafts were procured under controlled condition. Detailed information of the donation after brain and cardiac death (DBCD) donors was obtained from The Chinese Red Cross and the OPO records.\(^{106}\)
- All donors were in hospital’s intensive care unit before death (cause of death for each donor is supplied in a table).\(^{107}\)
that these could be extreme euphemisms for deaths caused by execution.104 105

Looking at all of the organ source ID statements by year of transplant, there are a total of 30 papers that either stated explicitly that no organs from prisoners were used (18) or indicated that organs were sourced voluntarily and/or with consent during the time period when executed prisoners were virtually the sole source (there were 120 volunteer donations across all of China in this period). These data are summarised in table 5, along with the same data for the whole set of included papers. Of the 445 papers, 192 (43%) report on research that took place when the only organs available for transplant were from executed prisoners, while another 148 (33%) spanned the start of the volunteer donor pilot so must include at least some data derived from executed prisoners.

The majority of the papers reporting on the identity of organ sources also reported some form of institutional ethics approval, but seven papers did not.37 38 44 79 94 96 107

Turning to the journals that published the 445 papers, a full list of these is in online supplementary file 6.

Seventeen journals published five or more papers during the study period. In this subset of 17, the proportion with ethics statements ranged from 38% to 100%, while the proportion with identity statements regarding sources ranged from 0% to 40% (table 6).

Finally, in terms of journals with specific policies banning publication of research based on use of prisoners’ organs, our study identifies one paper published in the American Journal of Transplantation36 and five papers published in Transplantation (the official journal of TTS) that appear to be in breach of their own stated policies.94 108-111 One of these has over 300 citations.109

**DISCUSSION**

This study shows that the majority of the published literature identified in this scoping review reporting research on transplants in China from 2000 to April 2017 fails to comply with ethical standards regarding exclusion of research based on organs procured from prisoners. The body of literature contains a large number of papers that certainly, or almost certainly include data from executed prisoners given China’s acknowledgement that during this period executed prisoners were the principal organ source. While TTS policy appears to have been partially successful in that the number of papers claiming IRB approvals rose steeply after that policy was published in 2006, the inclusion of this information has not addressed the major underlying concern about use of prisoners’ organs. This is because the ethics review process focuses on the protection of research participants and their informed consent for participation in research. In transplant research, it is the recipients of transplants who are protected by IRB review, rather than the organ donors. Therefore, claims about compliance with the Declaration of Helsinki are largely irrelevant regarding the use of prisoners’ organs in research. Few papers (14%) include any information about the identity of organ sources. Only half of these explicitly state that no organs were procured from executed prisoners, but many of these claims are incompatible with what is known about volunteer organ sources in China.

Our findings raise significant issues. First, there is the broad question of what to do about the large body of literature based on research using organs from prisoners. It can be argued that prior to 2006, the international transplant community was not aware that in China at the time, all transplants were procured from executed prisoners.
However, post-2006 and the publication of TTS policy, professional claims of ignorance are hard to support. This lack of vigilance on the part of reviewers, editors and publishers is morally concerning, given the large numbers of papers (over 85%) accepted for publication with no information at all on the source of organs, especially where individual journals have explicitly adopted relevant policy (Transplantation, American Journal of Transplantation).

Continued use of this research raises potential issues of complicity to the extent that the international community (including members of TTS, journal editors and peer-reviewers) condemn the use of executed prisoners’ organs in research, but nonetheless benefit from this practice by allowing or facilitating the publication of such research, and subsequently using the findings. The obligations of third parties to avoid complicity depend in part on the magnitude of the moral wrong in question.113 Some research uses of datasets that were obtained illicitly may be permissible.114 By comparison, there is broad consensus that it is unethical to make use of the data obtained from Nazi and Japanese medical experiments where the victims were killed or harmed in the course of the research.115–117 The use of research based on organs sourced from executed Chinese prisoners, many of whom are prisoners of conscience,21 falls at the severe end of this spectrum of moral wrongs in research. The obligation of third parties, such as peer-reviewers, publishers and editors to avoid complicity is therefore comparatively high in this case, warranting large-scale retractions and investigation of the 340 papers that are based exclusively or partially on data from executed prisoners (ie, all papers reporting on transplants that occurred prior to 2010 or spanning 2010: see table 5). In addition, due to lack of vigilance by the journals on reporting organ sources, readers risk witting or unwitting complicity to the extent that they use the published research findings. The continued presence of these papers in the literature creates moral hazard as it demonstrates that breaches of ethical standards in research will be ignored or tolerated, thereby removing incentives for future compliance with these standards.

Second, journal editors must decide how to handle published papers that use data from executed prisoners, and make almost certainly false claims about procuring organs from non-prisoner sources. In 29 of the 63 papers claiming or implying that organs were from non-prisoner sources and/or donated voluntarily or with consent, the claims are incompatible with what is known about voluntary donations across China in the relevant time period. There is less certainty regarding the falsity of claims in published papers reporting on transplants that took place between 2010 and 2014 given the existence of a pilot voluntary donation scheme. Determining the likely veracity of these claims requires sustained investigation, including of Chinese-language sources. Such investigation is possible, and has formed the basis for a retraction of a paper that falsely claimed more organs

### Table 6
List of journals publishing five or more papers, and numbers of those papers in which there were ethics and/or organ source identity statements

| Journal                                              | CiteScore* | Total papers in journal out of 445 (%) | Number of papers with ethics statement (%) | Number of papers with donor ID (%) |
|------------------------------------------------------|------------|----------------------------------------|-------------------------------------------|-----------------------------------|
| Transplantation Proceedings                         | 0.98       | 65 (15%)                               | 25 (38%)                                  | 12 (18%)                          |
| PLoS ONE                                             | 3.11       | 20 (4%)                                | 19 (95%)                                  | 5 (25%)                           |
| Clinical Transplantation                             | 1.67       | 16 (4%)                                | 9 (56%)                                   | 3 (19%)                           |
| Liver Transplantation                                | 2.50       | 15 (3%)                                | 12 (80%)                                  | 3 (20%)                           |

were procured from volunteers than there were reported volunteers at the relevant hospital.\textsuperscript{119–121} This is to date the only retraction in the literature. At the very least however, reviewers, editors and journals should be aware that prior to 2010 there were almost no voluntary donors, and that the alleged numbers of volunteer donors during the 2010–2014 pilot scheme were low (table 4). Given this situation, claims about volunteer sources for transplantation during these periods warrant scrutiny, with rejection of papers and author bans if adequate evidence of ethical organ sourcing is not provided.

Third, there is a pressing need for further reviews of the literature not included in this study. In particular, we need review of Chinese-language sources and English-language publications in China where a further large body of unethical research may be published, as well as review of papers published in languages other than English and Chinese. A future review of kidney transplant papers is also required, to fully document the extent of published unethical research.

Finally, there is a question regarding future publication of Chinese transplant papers. In our view, it is unacceptable to publish any papers that are highly likely to contain data derived from use of prisoners’ organs. This includes data from transplants up until the end of 2014, given the difficulty of establishing organ provenance and the demonstrated lack of veracity in the claims of at least some authors. However, even transplants post-2015 may involve prisoners’ organs.\textsuperscript{120} For this reason, we suggest an interim moratorium on publication of all relevant papers, pending an international summit to develop policy. A summit involving representatives from the International Committee of Medical Journal Editors, Committee on Publication Ethics, TTS and members of other relevant national and international transplant societies, together with China human rights experts, ethicists and any other relevant stakeholders could and should develop policy on handling future research. One outcome of this process could be the development of a checklist tool for all transplant papers, itemising mandatory information about organ sources. Given our lack of capacity in this study to report on papers involving kidney transplants due to missing information about the status of organ sources, one requirement of a checklist should be an unambiguous statement regarding whether organ sources were living or deceased. An international and widely adopted process of this kind would provide a strong incentive for China to move more rapidly towards an organ donation system that is ethical, transparent and verifiable. This incentive is currently lacking given the widespread publication of unethical research.

LIMITATIONS

The strengths of the study lie in its originality and robust methods. These give confidence that the results are reliable and likely to be conservative (given reasonable assumptions as described in the ‘Methods’ section) rather than to overestimate the findings. However, there are potential limitations. First, scoping reviews are less comprehensive than systematic reviews, making it possible that relevant papers were not identified and included. Second, we had to change our approach to data collection during the study, as the quality of data in the papers was often imprecise. This affected the study in two ways. We were not able to report on research involving kidney transplants due to lack of information as to whether sources were living or deceased; and we were not able to report on whether organs were obtained after death declared on cardiac or brain criteria as this information was inconsistently reported. Third, unless stated otherwise in the papers reporting on liver transplants, we have assumed the donors were deceased. It is possible that some of the transplants classified as deceased donor were from living split liver transplants, however we think the number is likely to be very low as deceased sourcing is the the most common type of transplant and numbers of living donor donations in China are low, at 7.37% of total cumulative liver transplants as of end 2011, according to official data.\textsuperscript{122} Fourth, we have reported on published literature, but during the period when only organs from executed prisoners were available, the pharmaceutical industry ran clinical trials on immunosuppressants for transplantation in China (including after 2007 when TTS policy was promulgated).\textsuperscript{123} Unpublished industry trials have not been included in our study. Finally, we have reported the total number of participants (and hence number of transplants) in the included studies, but this number is likely to be inflated by multiple publication of the same and overlapping research cohorts. However, as our aim was to report on whether or not published research met the ethical reporting standards mandated by TTS, we do not think this is a critical issue.

CONCLUSION

The transplant community has failed to implement ethical standards banning publication of research using material from executed prisoners. As a result, a large body of unethical published research now exists, raising questions of complicity to the extent that the transplant community uses and benefits from the results of this research. Our study has identified the extent of this problem as well as specific papers containing demonstrably false claims about organ sourcing. There has been a significant lack of vigilance and failure to adhere to accepted ethical standards by reviewers, editors and publishers. Researchers and clinicians who use this body of research risk complicity by implicitly accepting Chinese methods of organ procurement. We call for immediate retraction of all papers reporting research based on use of organs from executed prisoners, and an international summit to develop future policy for handling Chinese transplant research.
