This work systematically studied the structure, magnetic and electronic properties of the MXene materials Nd$_2$NT$_2$ (T = OH, O, S, F, Cl, and Br) via first-principles calculations based on density functional theory. Results showed that Nd$_2$NT$_2$ (T = OH, O, S, F, Cl, and Br) have half-metallic characteristics whose half-metallic band gap width is higher than 1.70 eV. Its working function ranges from 1.83 to 6.50 eV. The effects of strain on its magnetic and electronic structures were evaluated. Results showed that the structure of Nd$_2$NT$_2$ (T = OH, O, S, and Br) transitions from a ferromagnetic half-metallic semiconductor to a ferromagnetic metallic and ferromagnetic semiconductor under different strains. By contrast, the structures of Nd$_2$NF$_2$ and Nd$_2$NS$_2$ were observed to transition from a half-metallic semiconductor to a ferromagnetic metallic semiconductor under different strains. Calculations of the electronic properties of different proportions of the surface functional groups of Nd$_2$NT$_x$ (T = OH, O, and F; $x$ = 0.5, 1(I, II), and 1.5) revealed that Nd$_2$NO$_{1.5}$ has the characteristics of semiconductors, whereas Nd$_2$NO(II) possesses the characteristics of half-metallic semiconductors. The other structures were observed to exhibit the characteristics of metallic semiconductors. Prediction of Nd$_2$NT$_2$ (T = OH, O, S, F, Cl, and Br) increases the types of lanthanide MXene materials. They are appropriate candidate materials for preparing spintronic devices.

Keywords: two-dimensional, MXene, Lanthanum series, half-metallic characteristics, spin polarization

1 INTRODUCTION

As candidate materials for preparing spintronic devices with a high-density, a high read/write speed, and an ultra-small volume, two-dimensional ferromagnetic half-metallic materials are the key to the development of spintronic devices (Wolf et al., 2001; Hu et al., 2014; Kent and Worledge, 2015; Wang et al., 2021a). Ferromagnetic half-metallic materials have 100% spin polarization. In a spin state, they have metallic properties at the Fermi level. In another spin state, they exhibit semiconductor or insulator properties at the Fermi level. Since 2004, graphene has been experimentally prepared successfully (Novoselov et al., 2004). Graphene is a semiconductor with a zero band gap, a feature limits its application in magnetic equipment (Novoselov et al., 2004; Geim and Novoselov, 2007). Graphene can be applied to spintronic devices by improving graphene...
or developing graphene-like materials. Extensive research on graphene-like materials, such as hexagonal boron nitride, silicon, phosphorus, transition-metal dichalcogenides and transition-metal carbon (nitrogen) compounds (MXenes), is being conducted (Denk et al., 1994; Sevik, 2013; Liu et al., 2014; Naguib et al., 2014; Kranthi Kumar et al., 2015). MXenes have received increased attention because they have abundant types.

Two-dimensional MXene materials have been developed using HF corrosion body phase material Ti3AlC2 to remove Al atom experimentally and obtain Ti3C2 materials with a few layers (Naguib et al., 2011). MXene materials are represented by the formula M_{n+1}X_nT_x (n = 1, 2, 3), where M is a transition metal, X is either C or N, and T_x is a surface functional group. MXenes are becoming popular two-dimensional materials. Theoretical and experimental studies revealed that various MXene materials have intrinsic ferromagnetic half-metallicity, such as Cr2C, Cr2NO2, Fe2NO2, Co2NO2, Ni2NT2 (T = O, F, OH), and Mn2NT2 (T = O, OH, F) (Si et al., 2015; Wang, 2016; Wang and Liao, 2017; Frey et al., 2018). External conditions can be applied to induce Ti3NO2, Cr3C2, and Hf2MnC2O2 and obtain ferromagnetic half-metals (Chen et al., 2017; Zhang and Li, 2017; Sirirawdane et al., 2019). However, several MXene materials have semiconductor properties, such as Sc2CO2, Ti3CO2, and Cr3CT2 (T = F, OH, O, Cl) (Lee et al., 2014; Si et al., 2015; Zhou et al., 2016). Therefore, MXenes have rich magnetic and electronic properties that must be harnessed.

Most MXene materials have different sensitivities to surface functional groups and external conditions. Therefore, MXene functional materials can be feasibly designed by exploiting functional groups or external conditions. However, current research on MXene materials mostly focuses on transition metals and largely ignores MXene materials with lanthanide elements. Tan et al. studied the strain piezoelectric coefficient of La2CO2, a lanthanide MXene material, under axial strain. They reported that the formation energy was calculated to describe the thermodynamic stability of two-dimensional MXene material systems with different surface functional groups by using the following formula (Bekaert et al., 2020):

\[ E_T = E_{total}(Nd_2NT_2) - E_{total}(Nd_2N) - E_{total}(T_2) \]  

where \( E_{total}(Nd_2NT_2) \) is the total energy of Nd2NT2, \( E_{total}(Nd_2N) \) is the total energy of Nd2N, and \( E_{total}(T_2) \) is the total energy of \( T_2 \) (T = OH, O, S, F, Cl, and Br) of functional groups.

3 RESULTS AND DISCUSSION

3.1 Surface Functional Groups of the Structure

The top and side views of Nd2N after structural relaxation are shown in Figures 1A, C, respectively. The optimization results showed that Nd2N is a hexagonal crystal structure composed of Nd atoms on both sides and N atoms in the middle. This structure is similar to that of materials reported in the literature (Si et al., 2015; Zhang et al., 2021). Different methods for preparing MXene materials inevitably result in the formation of certain functional groups on their surface. In this study, six different functional groups present T2 (T = OH, O, S, F, Cl, and Br) in the optimized structure of Nd2N were investigated (Figures 1B, D). According to previous studies, the functional groups on the surface may be found at three sites, namely, on the top of Nd, on the top of N, and on the top of Nd at the bottom of both sides. In this study, the functional groups were observed to be located on the top of Nd at the bottom of both sides, similar to that reported in the literature (Wang and Liao, 2017; Zhang et al., 2021).

The lattice constants of Nd2N and Nd2NT2 and the bond lengths of Nd–N and Nd–T are listed in Table 1. The lattice constant of Nd2NT2 and the bond length of Nd–N are larger than those of Nd2N, indicating that the functional groups on the
surface can change the structure of Nd$_2$N. Nd$_2$NS$_2$ has the largest lattice constant (4.232 Å), whereas Nd$_2$NO$_2$ has the smallest lattice constant (3.755 Å). Moreover, the Nd–N and Nd–T bond lengths of Nd$_2$NS$_2$ are longer than those of Nd$_2$NO$_2$ because both O and S belong to the VIA family and have similar properties. The radius of the S atom is greater than that of the O atom. The lattice constants of Nd$_2$NF$_2$, Nd$_2$NCl$_2$, and Nd$_2$NBr$_2$ are 3.796, 3.911, and 3.971 Å, respectively. The lattice constants increase with the increase in the atomic radius of the VIA family, and the bond lengths of Nd–N and Nd–T gradually increase. However, the bond length of Nd–T is quite different. Nd–Br has the maximum bond length (3.015 Å), whereas Nd–O has the minimum bond length (2.280 Å), indicating that the bonding intensity of Nd and O is greater than that of Nd–Br. However, the bond length of Nd–N is 2.62–2.69 Å, indicating that although the different surface functional groups have an effect on the structure of the monolayer Nd$_2$N, their effect on the bond length of this structure is less than that on its lattice constant.

### 3.2 Magnetic and Thermodynamic Stability

The atomic resolution magnetic moments and formation energies of Nd$_2$N and Nd$_2$NT$_2$ (T = OH, O, S, F, Cl, and Br) were calculated to assess their magnetic and thermodynamic stability (Table 2). The magnetic moments of monolayer Nd$_2$N (up to 8.95 $\mu_B$) are higher than those of Nd$_2$NT$_2$ (T = OH, O, S, F, Cl, and Br). However, the magnetic moments of Nd$_2$N(OH)$_2$, Nd$_2$NF$_2$, Nd$_2$NCl$_2$, Nd$_2$NBr$_2$, Nd$_2$NO$_2$, and Nd$_2$NS$_2$ are 7.01, 7.01, 7.00, 7.00, 5.00, and 4.98 $\mu_B$, respectively. The magnetic moment of Nd$_2$N mainly comes from two Nd atoms, and the contribution of the N atom to the total magnetic moment is small. However, with the addition of –OH, the total magnetic moment is reduced to 7.01 $\mu_B$. The magnetic moment of the nonmagnetic elements is also reduced because of the strengthening of hybridization between the atoms that strengthened the magnetic coupling effect and reduced the magnetic moment. In the structures of Nd$_2$NO$_2$ and Nd$_2$NS$_2$, the total magnetic moment is substantially reduced primarily because of the fact that the magnetic moment of the N atom of the Nd atom is remarkably smaller. Moreover, the magnetic moments of the nonmagnetic elements O and S in the induced surface functional groups are considerably smaller than those of the magnetic elements, indicating that the bonds between surface functional groups have an effect on the structure of the monolayer Nd$_2$N, their effect on the bond length of this structure is less than that on its lattice constant.

### Table 2 | Total atomic magnetic moment ($M_{total}$) and atomic resolution magnetic moment ($M_\mu_B$), and formation energy ($E_F$) of the two-dimensional MXene materials Nd$_2$N and Nd$_2$NT$_2$ (T = OH, O, S, F, Cl, and Br).

| Structure | $M_{Nd}(\mu_B)$ | $M_{N}(\mu_B)$ | $M_{T}(\mu_B)$ | $M_{total}(\mu_B)$ | $E_F$(eV) |
|-----------|-----------------|----------------|----------------|---------------------|-----------|
| Nd$_2$N   | 9.04            | 0.00           | —              | 8.95                | —         |
| Nd$_2$N(OH)$_2$ | 7.24       | -0.19          | -0.04          | 7.01                | -25.92    |
| Nd$_2$NO$_2$ | 6.46       | -0.88          | -0.58          | 5.00                | -16.98    |
| Nd$_2$NS$_2$ | 6.76       | -1.02          | -0.76          | 4.98                | -10.42    |
| Nd$_2$NF$_2$ | 7.24       | -0.19          | -0.04          | 7.01                | -14.75    |
| Nd$_2$NCl$_2$ | 7.26       | -0.20          | -0.06          | 7.00                | -10.47    |
| Nd$_2$NBr$_2$ | 7.28       | -0.20          | -0.08          | 7.00                | -9.016    |
the O and S atoms and Nd atom are relatively intense, resulting in a sharp decrease in atomic localization. In addition, the total magnetic moment of the structures of Nd$_2$NF$_2$, Nd$_2$NCl$_2$, and Nd$_2$NBr$_2$ remains 7.00 $\mu_B$. The increase in the amplitude of Nd and the F, Cl, and Br atoms is the same as that in the decrease in their amplitude. By comparison, the magnetic moment of the N atom remains low.

After the structural and magnetic properties of the materials were determined, the phonon spectrum of monolayer Nd$_2$N and the formation energy of Nd$_2$NT$_2$ (T = OH, O, S, F, Cl, and Br) were further calculated. According to the phonon spectrum of Nd$_2$N, it has good dynamic stability (Figure 2). Equation 1 was also used to calculate the formation energy of Nd$_2$NT$_2$ (T = OH, O, S, F, Cl, and Br). Nd$_2$N(OH)$_2$ has the smallest formation energy of $-25.92$ eV, whereas Nd$_2$NBr$_2$ has the largest formation energy of $-9.016$ eV (Table 2), indicating an intense interaction between the metals and the surface functional groups. When the surface functional groups are F, Cl, and Br (VIIA group), the formation energy gradually decreases (Table 2). However, the surface functional groups O and S (VIA group) also show a similar rule. According to previous studies, on the surface functional groups of MXene structures, the formation energy can easily change from high to low under certain conditions. The formation energy of the –OH structure with surface functional groups is smaller than that of the O, S, F, Cl, and Br structures with surface functional groups (Table 2), suggesting that MXene materials with O, S, F, Cl, and Br as functional groups should not be washed or stored in H$_2$O during preparation to prevent them from being converted into –OH MXene materials (Perdew et al., 1996).
3.3 Electronic Properties

The electronic properties of Nd$_2$N and Nd$_2$NT$_2$ (T = OH, O, S, F, Cl, and Br) were evaluated by calculating and plotting the energy band structure diagram (Figure 3). The spin up and the spin down of the energy band structure of Nd$_2$N pass through the Fermi level, indicating that it has ferromagnetic characteristics. In the spin down channel, the energy band density near the Fermi level is relatively sparse, indicating that the energy band structure can be changed under certain conditions, which are described below.

1) In the energy band structure of Nd$_2$NT$_2$ (T = OH, F, Cl, and Br), the spin up energy band at the Fermi level passes through the Fermi level, whereas the spin down energy band has an energy band gap, indicating that it has semimetal characteristics. The spin up energy band has an energy band gap near the Fermi level, indicating that the structure may change from a semimetal to a semiconductor under certain conditions.

2) In the band structure of Nd$_2$NT$_2$ (T = O and S), the spin up band at the Fermi level passes through the Fermi level, suggesting that it has metal characteristics. However, the spin down band has an energy band gap at the Fermi level, reflecting the nature of a semiconductor. Therefore, there is 100% spin polarization at the Fermi level, indicating that it has semimetal characteristics. According to the energy band structure, the band gap width between the spin down valence band and the Fermi surface is approximately 0.2–0.6 eV, and the band gap width between the spin down conduction band and the Fermi surface is greater than 3 eV, indicating that the structure does not readily change from a half-metal to a metal. Theoretically, the half-metallicity remains stable under certain external conditions.

3) The spin down band gap width of the semimetal was counted. Nd$_2$N(OH)$_2$ has the smallest band gap width (1.72 eV), whereas Nd$_2$NO$_2$ has the largest band gap width (4.61 eV) (Figure 3H). Therefore, the half-metallicity can remain stable within a certain range.

The calculated total density of states (TDOS) of Nd$_2$N and Nd$_2$NT$_2$ (T = OH, O, S, F, Cl, and Br) are provided in Figure 4. As can be seen from the TDOS graphs, the polarization peak of Nd$_2$N(OH)$_2$ moves to the high energy region, and their band gap width increase. However, the spin down band gaps of Nd$_2$NO$_2$, Nd$_2$NS$_2$, Nd$_2$NF$_2$, Nd$_2$NCl$_2$, and Nd$_2$NBr$_2$ exhibit similar behavior changes, and the only differences are in the energy range of spin polarization peaks, which gradually move to the high-energy region.

3.4 Work Functions of Nd$_2$NT$_2$ (T = OH, O, S, F, Cl, and Br)

Work function, as a reference for charge transfer, is a key parameter. The definition of work function ($\phi_{\text{ef}}$) is as follows (Vanderbilt, 1990):

$$\phi_{\text{ef}} = E_{\text{vacuum}} - E_F$$  (2)

where $E_{\text{vacuum}}$ represents the energy of the surface electron energy level in the vacuum, and $E_F$ is the Fermi level of the
FIGURE 5 | Calculated electrostatic potentials along the Z direction of Nd$_2$NT$_2$ (T = OH, O, S, F, Cl, and Br), while (A) Nd$_2$N(OH)$_2$, (B) Nd$_2$NO$_2$, (C) Nd$_2$NS$_2$, (D) Nd$_2$NF$_2$, (E) Nd$_2$NCl$_2$, (F) Nd$_2$NBr$_2$, respectively. The black arrow indicates the difference from vacuum level to the Fermi level. The black dashed line denotes the Fermi level.

FIGURE 6 | Total magnetic moments of monolayer Nd$_2$NT$_2$ (T = OH, O, S, F, Cl, and Br) under biaxial strain. (A) Nd$_2$N(OH)$_2$, (B) Nd$_2$NO$_2$, (C) Nd$_2$NS$_2$, (D) Nd$_2$NF$_2$, (E) Nd$_2$NCl$_2$, (F) Nd$_2$NBr$_2$. FM, FHM, and FS denote ferromagnetic metallic, ferromagnetic half-metallic, and ferromagnetic semiconductor, respectively.
MXene material. The electrostatic potentials of Nd2NT2 (T = OH, O, S, F, Cl, and Br) are calculated using Eq. 2 and plotted in Figure 5. The work function of Nd2Ni is approximately 1.186 eV, whereas that of Nd2N(OH)2, Nd2NO2, Nd2NS2, Nd2NF2, Nd2NCl2, and Nd2NBr2 is 1.83, 5.38, 6.50, 2.22, 4.33, and 4.40 eV, respectively. The work function of –OH is 1.6–2.8 eV, similar to that reported in the literature (Khazaei et al., 2013). Moreover, the work function of Nd2NT2 (T = OH, F, Cl, and Br) increases as VIIA atoms are introduced. The work function of Nd2NO2 is evidently lower than that of Nd2NS2. The work functions indicate that lanthanide MXene materials have potential applications in spintronic devices.

3.5 Strain Effect
The effects of strain on the magnetic and electronic structure of monolayer Nd2NT2 (T = OH, O, S, F, Cl, and Br) were evaluated by calculating the magnetic moment under different biaxial strains (Figure 6). Theoretical studies indicated that the electronic and magnetic properties of the monolayer MXenes Ti2C and Ti2N are tunable by strain (Clark et al., 2005; Sternik and Wdowik, 2018). Thus, biaxial strain was applied to monolayer Nd2NT2 (T = OH, O, S, F, Cl, and Br) by using the following formula:

$$\varepsilon = \frac{L - L_0}{L_0}$$  \hspace{1cm} (3)

where $L$ and $L_0$ are the lattice constants of strain and the equilibrium, respectively. Positive and negative $\varepsilon$ values correspond to tensile and compressive strain, respectively. Under different strains, both Nd2NF2 and Nd2NCl2 transition from a ferromagnetic half-metallic structure to a ferromagnetic metallic structure (Figure 6), and their total magnetic moment is maintained is from 6.5 to 9.0 $\mu_B$. By comparison, Nd2N(OH)2, Nd2NO2, Nd2NS2, and Nd2NBr2 transition from a ferromagnetic half-metallic structure to a ferromagnetic metallic structure and a ferromagnetic semiconductor under different strains. Notably, the total magnetic moments of the transition of Nd2NO2 and Nd2NS2 range from 5 to 7 $\mu_B$ under strain.

3.6 Electronic Properties of Different Proportions of the Surface Functional Groups of Nd2NTx (T = OH, O, F; x = 0.5, 1(I, II), and 1.5)
Surface functional groups have a great influence on the electronic properties of MXene materials (Xie et al., 2014). The influence of different proportions of the surface functional groups of the Nd2NTx materials on their electronic properties was assessed at proportions of $x = 0.5, 1, 1.5$ (Figure 7). $x = 1$ has two types; in type I, the functional groups are distributed on both sides, whereas in type II, the functional groups are distributed on one side only. After geometry optimization, TDOS was calculated (Figure 8).

The structures of Nd2N(OH)x and Nd2NFx exhibit metal characteristics because of the asymmetry of their surface functional groups. When the surface functional group is 100%, the material has...
half-metallic characteristics. This result provides a direction for detecting the richness of surface functional groups experimentally.

When \( x = 0.5 \) and 1 (type I), the structure of Nd\(_2\)NO\(_x\) exhibits metal characteristics. However, when \( x = 1 \) (type II), an obvious band gap is observed in the spin downward at the Fermi level, indicating that it has half-metal characteristics. Unexpectedly, when \( x = 1.5 \), both spin up and spin down have a symmetric band gap width at the Fermi level, indicating that it has the characteristics of a semiconductor. This result provides a reliable direction for the regulation of electronic properties by controlling the richness of surface functional groups experimentally.

4 DISCUSSION

The structural, magnetic, and electronic properties of Nd\(_2\)N and Nd\(_2\)NT\(_2\) (T = OH, O, F, Cl, and Br) were evaluated via first-principles calculations based on density functional theory. According to the calculated phonon spectrum and formation energies, Nd\(_2\)N and Nd\(_2\)NT\(_2\) (T = OH, O, F, Cl, and Br) are stable. Owing to the effects of surface functional groups on the electronic properties of Nd\(_2\)NT\(_2\) (T = OH, O, F, Cl, and Br), it exhibits the characteristics of a half-metal, and its band gap width is higher than 1.70 eV. The work function ranges from 1.83 to 6.50 eV, indicating that lanthanide MXene materials have potential applications in spintronic devices. Under different strains, Nd\(_2\)NT\(_2\) (T = OH, O, S, and Br) transition from a ferromagnetic half-metallic structure to a ferromagnetic metallic structure and a ferromagnetic semiconductor. However, the structures of Nd\(_2\)NF\(_2\) and Nd\(_2\)NS\(_2\) transition from a half-metallic structure to a ferromagnetic metallic structure under different strains. Calculation of the electronic properties of different proportions of the surface functional groups of Nd\(_2\)NT\(_x\) (T = OH, O, F; \( x = 0.5, 1 \) (I, II), and 1.5) revealed that Nd\(_2\)NO\(_{1.5}\) has the characteristics of a semiconductors, whereas Nd\(_2\)NO(II) has the characteristics of a half-metal. The other structures show the characteristics of a metal. This study demonstrated that new lanthanide MXene materials have a high application potential in spintronic devices.
