Abstract: Plant sterols are compounds with multiple biological functions, mainly cholesterol-reducing. There are no comprehensive databases on plant sterols, which makes it difficult to estimate their intake in the Polish population. In this study we used international food databases, supplemented by scientific data from the literature, to create a database on plant sterols in the food consumed in Poland to assess the size and sources of dietary plant sterols in the adult population of Poland. The literature search was conducted using PubMed, Web of Science, Scopus, and Google Scholar to identify possible sources of published food composition data for plant sterols. The study group consisted of 5690 participants of the WOBASZ II survey. We identified 361 dietary sources of plant sterols based on the consumption of foods and dishes reported by participants. Cereals and fats provided 61% of the total plant sterols, and together with vegetables and fruits, this totaled 80%. Total plant sterol intake for the Polish population was 282.97 mg/day, and divided by men and women was 320.77 and 252.19 mg/day, respectively. Canola oil provided the most plant sterols at 16.92%, followed by white bread at 16.65% and soft margarine at 8.33%. This study found that the database of plant sterols facilitates the calculation of plant sterols in the typical Polish diet, and the results are comparable to those of other studies, despite different methodologies of nutritional assessment and slightly different databases. The main sources of dietary plant sterols did not differ from the data for other populations. This study confirmed the observations of other research that women’s diets may have a higher plant sterol density compared to men.

Keywords: plant sterols; database; Polish population.

1. Introduction

Plant sterols are bioactive phytocompounds with a molecular structure similar to cholesterol [1]. The absorption of dietary cholesterol from diets rich in phytosterols is reduced by various mechanisms, mainly associated with the displacement of cholesterol from lipid micelles [2]. To date, more than 250 phytosterols have been identified, which include plant sterols and their saturated forms, stanols [3, 4]. In various food sources, β-sitosterol is predominant and accounts for approximately 80% of the phytosterol intake in the diet [5]. Clinical evidence shows that phytosterols have a moderate LDL- and triglyceride-lowering effect [6, 7]. Phytosterols are also considered moderately active antioxidants [8] and have immunomodulatory properties [9]. Sitosterol may suppress obesity-related chronic inflammation by reducing circulating interleukin-6 and TNF-α [10].
A growing body of evidence suggests that phytosterols may be an alternative and/or complementary therapy for patients with obesity and diabetes [3]. Consumption of naturally occurring plant sterols has been found to be associated with a lower risk of first myocardial infarction in men [11]. In addition, high doses of plant sterols in the diet, especially β-sitosterol, have been found to prevent the development of cancer [12, 13].

Food sources with the highest plant sterol content include vegetable oils, mainly corn oil (746 mg/100 g), and sesame seeds (714 mg/100 g) [14]. A good source of phytosterols are nuts, which provide 30–220 mg/100 g of phytosterols and cereals that contain phytosterols in the amount of 35–198 mg/100 g [15]. Vegetables contain smaller amounts of phytosterols, with 4–40 mg/100 g, and fruits contain 4–24 mg/100 g [15]. Consumption studies have shown that due to the frequency and volume of consumption, the suppliers of plant sterols are mainly bread, cereals, fats, and vegetables [3, 5].

Unlike the various databases on food composition, there are no comprehensive databases on plant sterols, which makes it difficult to estimate the intake of plant sterols in populations, as well as their further calculations in epidemiological studies. Food composition databases in some countries actually contain data on plant sterols, but they are incomplete for some food products [14, 16]. This raises methodological concerns related to the calculation and comparison of plant sterol intake in population studies. Therefore, this work attempted to use international food databases, additionally supplemented by scientific data from the literature, to create a database on plant sterols in the food consumed in Poland to assess the size and sources of dietary plant sterols in the adult population of Poland.

2. Materials and Methods

2.1. Study group and data collection

The study group consisted of 5690 participants (2554 men and 3136 women) of the National Multicenter Health Survey II (the Polish acronym is WOBASZ II). WOBASZ II is a cross-sectional study representative of the Polish adult population aged 20 years and over, which was carried out by the National Institute of Cardiology (formerly the Institute of Cardiology), Warsaw, Poland, in the years 2013–2014, in collaboration with five national medical universities. The design and methods of the WOBASZ II survey have been described in detail elsewhere [17]. Daily food consumption data were collected by trained interviewers using a single 24 h dietary recall method. The overall evaluation included a sample of 6170 participants, 480 of whom were excluded due to missing or unreliable dietary recalls. A flowchart of the participants is shown in Figure 1. The WOBASZ II study was approved by the Bioethics Committee of the National Institute of Cardiology (no. 1344), as was the current study (no. 1837). Written informed consent was obtained from all participants.

Data on the demographic status, diseases, leisure time physical activity, tobacco use, community size, marital status, and education level of the participants were collected using a standardized questionnaire developed for the WOBASZ II survey. Height and weight measurements were taken by personnel trained in standard procedures. Body mass index (BMI) was calculated from body weight in kilograms divided by the square of the height in meters. Blood pressure (BP) was measured three times on the right arm after 5 min of rest in a sitting position at 1 min intervals, and final BP was reported as the mean of the second and third measurements. The general characteristics of the study group are shown in Table 1.
Figure 1. Flow chart of the study participants.

Table 1. General description of the studied population.

| Trait                        | Men          | Women        | Men and women |
|------------------------------|--------------|--------------|--------------|
|                              | N=2554       | N=3136       | N=5690       |
| Age (year) (mean ± SD)       | 48.79 ± 16.27| 50.23 ± 16.54| 49.58 ± 16.43|
| BMI (kg/m²) (mean ± SD)      | 27.42 ± 4.55 | 26.96 ± 5.65 | 27.17 ± 5.19 |
| Systolic BP (mmHg), (mean ± SD) | 134.44 ± 18.19 | 127.6 ± 19.71 | 130.67 ± 19.34 |
| Diastolic BP (mmHg), (mean ± SD) | 81.51 ± 10.91 | 79.19 ± 10.62 | 80.23 ± 10.81 |
| Fasting glucose (mmol/l), mean ± SD | 5.65 ± 1.6 | 5.38 ± 1.32 | 5.50 ± 1.46 |
| Total cholesterol (mmol/l), mean ± SD | 5.21 ± 1.33 | 5.19 ± 1.22 | 5.20 ± 1.27 |
| LDL-cholesterol (mmol/l), mean ± SD | 3.19 ± 1.04 | 3.11 ± 1.02 | 3.15 ± 1.03 |

Diseases (%)

Hypertension¹ | 49.56 | 41.69 | 45.22 |
Hypercholesterolemia ² | 68.86 | 66.03 | 67.30 |
Diabetes³ | 11.86 | 9.96 | 10.82 |

Age groups (%)

20–40 years | 34.92 | 32.27 | 33.46 |
41–60 years | 38.32 | 38.83 | 38.60 |
61–74 years | 20.52 | 20.34 | 20.42 |
>74 years | 6.24 | 8.56 | 7.52 |

Commune size (%)

<8.000 inhabitants | 33.83 | 36.32 | 35.20 |
8.000–40.000 inhabitants | 30.70 | 30.64 | 30.67 |
>40.000 inhabitants | 35.47 | 33.04 | 34.13 |

Marital status (%)

married | 70.19 | 63.87 | 66.71 |
single ⁴ | 29.81 | 36.13 | 33.29 |
### Level of education (%)

- **under middle**: 14.74, 19.06, 17.12
- **middle**: 36.89, 40.52, 38.89
- **academic**: 17.09, 22.09, 19.85
- **vocational**: 31.28, 18.33, 24.14

### Smoking status (%)

- **current smokers**: 28.95, 18.66, 23.28
- **past smokers**: 33.62, 18.82, 25.46
- **never smokers**: 37.43, 62.52, 51.26

### Leisure-time physical activity (%)

- **low level**: 54.98, 53.67, 54.25
- **middle level**: 14.81, 15.68, 15.29
- **high level**: 27.50, 28.54, 28.08
- **seasonally**: 2.71, 2.11, 2.38

### BMI (kg/m²) (%)

- **underweight (BMI<18.5)**: 0.90, 2.20, 1.61
- **normal (BMI 18.5-24.99)**: 30.07, 38.88, 34.91
- **overweight (BMI 25-29.99)**: 43.93, 31.76, 37.25
- **obesity (BMI≥30)**: 25.10, 27.16, 26.23

### Use of phytosterol-enriched margarines (%)

- 1.96, 1.85, 1.90

1. Hypertension: systolic blood pressure SBP ≥140 mmHg or diastolic blood pressure DBP ≥90 mmHg, or hypertension was declared in an interview;
2. Hypercholesterolemia: TC ≥5 mmol/l or LDL-C ≥3 mmol/l or the participant was taking a lipid-lowering medication.
3. Diabetes: blood glucose level was ≥7.0 mmol/L or diabetes was declared in an interview;
4. Singles: widows/widowers, unmarried, divorced, in separation;
5. Education level: under middle - no education, partial or completed education for primary level, partial secondary education; middle - secondary education, partial academic education, high - tertiary education, vocational - vocational based on primary or on middle school;
6. Physical activity at leisure (for example jogging, cycling, swimming, gardening for at least 30 min a day): low level - no such physical activity, once a week or less, middle level - everyday, almost every day, seasonally (e.g. skiing in winter or on the plot in summer).

### 2.2. Plant sterol database and calculation of dietary intake

The present study identified 361 dietary sources of plant sterols based on the consumption of foods and dishes reported by participants in the WOBASZ II survey. For the dishes, the individual ingredients were extracted according to recipes of the National Institute of Food and Nutrition of Poland, taking into account the yield factors of the dishes. Foods were grouped into 10 categories: cereals (flour, bread, breakfast cereals, bran, groats, and pasta), fruit (processed and non-processed), vegetables (processed and non-processed), potatoes, legumes, fats and oils (oils, margarine, and mayonnaise), coffee (instant and infusion), cookies and cakes, chocolate (chocolate and chocolate candies and bars), and other foods (tea, beer, wine, sodas, mustard, nuts, and seeds). Foods enriched with phytosterols were not included in these calculations, because not all manufacturers were willing to disclose their formulations regarding individual phytosterols. A small proportion of subjects who consumed phytosterol-enriched products was found (Table 1).

Since there is no plant sterol database in Poland, its establishment for the purpose of this study was based on international databases, which were published in English and are publicly available [14, 16].
The plant sterol content is not available in the databases for many of the foods consumed in the WOBASZ II study; therefore, a literature review was conducted to search for reliable data sources that would supplement the data taken from international databases. The literature search was conducted using PubMed, Web of Science, Scopus, and Google Scholar to identify possible sources of published food composition data for plant sterols. The search terms included phytosterols, plant sterols, β-sitosterol, campesterol, stigmasterol combined with food, cereals, vegetables, fruit, berries, nuts, seeds, legumes, beverages, coffee, tea, wine, soda, chocolate, pastry, and cookies.

The plan was to select data sources that were as complete as possible in terms of individual plant sterols (β-sitosterol, campesterol, and stigmasterol). For the total plant sterol content, the full data reported by databases or scientific sources were used or, in the absence of relevant data, the available data for plant sterol content were aggregated. The quality of the data was assessed according to the procedure described by Rand et al. [18], which takes into account the analytical method used, the number of samples, the sample handling procedures, the sampling plan for the selection of foods, and the analytical and quality assurance. The currently available techniques for sterol analysis are gas chromatography (GC), high-pressure liquid chromatography (HPLC), and supercritical fluid chromatography (SFC). GC/FID (flame-ionization detection) or GC/MS (mass spectrometry) can be considered the methods of choice for the determination of phytosterols in foods and diets [19]. For most of the studies, all of the quality criteria were met. For some food products, the number of studies was limited to only one publication; although they did not meet all quality criteria, they were included in the developed database due to lack of other publication sources. Finally, data from 13 data sources were included in the database.

In this study, data for fats and oils were extracted from the British database of Food Composition [16], the USDA Database [14], and Normen et al. [20]. Data on plant sterols in cereals were extracted from the British database of Food Composition [16] and Normen et al. [21]. Most of the data for vegetables and potatoes were taken from Normen et al. [22]. Data gaps in the vegetables group were filled in from the publications by Han et al. [23], Piironen et al. [24], Ryan et al. [25], the British database of Food Composition [16], and the USDA Nutrient Database [14]. The plant sterol contents in fruits and berries were compiled from the USDA Database [14], Piironen et al. [24], Normen et al. [22], and Han et al. [23]. The plant sterol contents in nuts and seeds were taken from the USDA Database [14], the British database of Food Composition [16], and Normen et al. [20]. The plant sterols for legumes were compiled from Li et al. [26], Han et al. [23], the USDA Database [14], Ryan et al. [25], and Yamaya et al. [27]. Data for fruit and vegetable juices, sodas, tea, and beer were taken from Decloe et al. [28]. Data for the plant sterols in wines were taken from Ruggiero et al. [29]. The plant sterol content in the plastic fraction of coffee was taken from Čížková et al. [30] and recalculated per 100 g of coffee. For pastry and cookies, data were extracted from the British database of Food Composition [16], the USDA Database [14], and Piironen et al. [24]. For chocolate and chocolate candies, data were compiled from Normen et al. [20].

For some foods, the values of plant sterols (total and individual) were not found, e.g., no studies were found for chard. No data were found for campesterol or stigmasterol in radishes, wines, and mushrooms. For foods such as chives, blueberries, cherries, pears, raspberries, blackcurrants, walnuts, and pumpkin seeds, no value was found for stigmasterol. Therefore, the values obtained for the sum of individual plant sterols could be lower than the total plant sterol content.

Plant sterol daily intake was determined by multiplying the daily consumption of individual food items by the respective total plant sterols, such as the β-sitosterol, campesterol, and stigmasterol contents, in these food items and then summed up.

2.3. Data analysis
Total phytosterol intake, including β-sitosterol, campesterol, and stigmasterol, was calculated by multiplying the daily consumption of individual food items by the respective phytosterol contents in these products. Additionally, the contribution of individual groups of food products and their ingredients to the consumption of different phytosterols was studied. Descriptive statistics were applied to describe the continuous variables (means and standard deviations), and the percentages of the respective values were used for categorized variables. The contributions of food categories and individual food items to the intake of particular total and individual phytosterols are presented as percentages. A non-parametric Wilcoxon test was used to investigate the differences between phytosterols and phytosterol intake/1000 kcal in groups of men and women. The level of significance was considered $p < 0.05$. Data analyses were processed using Statistical Analysis System (SAS; version 9.4, SAS Institute Inc., Cary, NC, USA).

3. Results

This study identified the top 10 food categories that provided plant sterols for the Polish population, which were cereals, vegetable fats and oils, vegetables, fruits, coffee, cookies and cakes, chocolate products, potatoes, and legumes. The other food products providing lower amounts of plant sterols were classified into the category of “other food products.” Among all of these categories, cereals and fats provided 61% of the total plant sterols, and together with vegetables and fruits, this totaled 80%. Total plant sterol intake in this study was 282.97 mg/day, and divided by men and women was 320.77 and 252.19 mg/day, respectively (Table 2). Considering individual foods (mg/day), canola oil provided the most plant sterols at 16.92%, followed by white bread at 16.65% and soft margarine at 8.33%. Among vegetables and fruits, there was no single significant source of plant sterols, but raw fruits and vegetables provided the predominant amounts of plant sterols (9.78% and 7.27%, respectively). This pattern of plant sterol sources was reflected in men, while among women, the main contributor was canola oil, followed by white bread, raw fruits, raw vegetables and soft margarine.

Tables 3–5 show the contribution of food categories to the consumption of individual plant sterols such as β-sitosterol, campesterol, and stigmasterol. The mean β-sitosterol consumption was 175.98 mg/day, while the intake of campesterol and stigmasterol was 59.06 mg/day and 24.63 mg/day, respectively.

The main food categories providing β-sitosterol were cereals (29.19%), fats (28.86%), fruits (14.20%), and vegetables (8.70%), with a total share of 80.95% of the β-sitosterol supply (Table 3.). Among the food products, β-sitosterol was supplied by canola oil (15.88%), followed by wheat bread (14.88%) and soft margarine (9.02%). Women had a lower β-sitosterol intake compared to men at 158.14 mg/day vs. 197.89 mg/day, respectively.

The main sources of campesterol were fats (44.95%) and cereal products (31.81%), which together accounted for 76.76% of the campesterol intake (Table 4.). For individual products, campesterol was supplied by canola oil (33.43%), white bread (16.30%), and soft margarines (8.11%). Men consumed more campesterol compared to women (69.16 vs. 50.83 mg/day, respectively).

As for stigmasterol, its main sources were the following product groups: coffee (25.10%), vegetables (23.22%), fats (16.85%), and cereal products (12.93%).

The foods supplying the highest amounts of stigmasterol included coffee (as a food product; 25.10%), soft margarine (11.82%), and white bread (6.48%).

The intake of stigmasterol was higher in men at 26.36 mg/day compared to women at 23.22 mg/day.

On a per milligram basis, men consumed more total and individual plant sterols (Table 6.). However, per 1000 kcal, significantly more plant sterols as total as individual
sterols were consumed by women (p < 0.0001), except for campesterol, for which the difference was not statistically significant.

Table 6. Comparison of total and individual sterol intakes (in mg and in mg/1000 kcal) by men and women.

| Plant sterols (mg)          | Men         | Women       | p-value |
|-----------------------------|-------------|-------------|---------|
| Total plant sterols         | 320.8       | 252.2       | <0.0001 |
| Total plant sterols/1000 kcal | 141.0       | 154.2       | <0.0001 |
| β-sitosterol                | 197.8       | 158.1       | <0.0001 |
| β-sitosterol/1000 kcal      | 87.1        | 96.8        | <0.0001 |
| Campesterol                 | 69.2        | 50.8        | <0.0001 |
| Campesterol/1000 kcal       | 29.8        | 30.4        | 0.2279  |
| Stigmasterol                | 26.4        | 23.2        | <0.0001 |
| Stigmasterol/1000 kcal      | 12.0        | 14.8        | <0.0001 |

4. Discussion

This is the first report on dietary plant sterol intake and its dietary sources in the Polish population. Due to the lack of plant sterols in Polish food composition tables, the database used for this study included international databases available in English supplemented with data from research papers on plant sterol contents in food products. In our study, the consumption of plant sterols from enriched food products was not taken into consideration, since the percentage of consumers of phytosterol-enriched products was low (2%). In comparison, it has been estimated that regular consumers of products with added plant sterols represent approximately 10%–15% of the EU population [31].

Typical contemporary Western diets provide much lower amounts of phytosterols [32] than estimated for distant human ancestors, whose diet provided 1 g/day of phytosterols [33]. The dietary phytosterol intake in population studies is usually between 200 and 400 mg/day [34, 35], even in those populations with more beneficial dietary habits [36], and this amount is considerably lower to show significant LDL cholesterol-lowering effects demonstrated for 1 g of phytosterols [37]. Contrary to this, the PREDIMED study found that even small amounts of plant sterols from natural foods may exert a cholesterol-lowering effect [38]. A recent meta-analysis of 124 clinical studies demonstrated that a phytosterol intake between 0.6 and 3.3 g/day is associated with a gradual decrease in the concentration of LDL-cholesterol from 6% to 12% [39]. Scientific evidence indicates that even moderate doses of phytosterols delivered via a normal diet can provide a protective effect on the lipid profile by reducing cholesterol absorption [40, 41], but a lipid-lowering effect may depend on the inter-individual variation in response to phytosterols [42].

The daily intake of total plant sterols in our study (283 mg/day) is similar to that of the Spanish population, where it was estimated to be 276 mg, with the largest contribution of beta-sitosterol (79.7%) [5]. A similar value (300 mg/day) has also been found in the U.K. population [35]. Our results confirm earlier findings that β-sitosterol is the most important contributor (67.8%) to the intake of total dietary plant sterols. Regarding gen-
nder differences in plant sterol intake, in our study, the intake was 320.77 mg/day for men and 252.19 mg/day for women. These results are similar to a Finnish study where gender differences in plant sterol intake were observed among men and women [43], but in contrast to the U.K. population where such differences were not observed [35].

As per our study, the consumption pattern of total plant sterols from major food groups such as cereal products, vegetable oils and fats, vegetables, and fruits is similar to the intervention group in the PREDIMED study and to the U.K. population [35, 38]. Of these, cereal products and oils provided nearly 61% of plant sterols, and when combined with vegetables and fruits, nearly 80%. However, unlike the PREDIMED study, where legumes were the fifth contributor to total plant sterols, in our study, the additional sources of plant sterols included coffee, cookies and cakes, chocolate products, and potatoes, while legumes were only ninth in providing plant sterols. Together, these minor sources of plant sterols accounted for 16.68% of plant sterol intake. The other sources of plant sterols accounted for 3.55%; these included, among others, nuts and seeds, which are normally a good source of plant sterols, but because of their low intake [44], they were not a significant source of plant sterols for the Polish population. The PREDIMED intervention study indicated an important role for the Mediterranean diet, in combination with nuts, in providing plant sterols in the diet and providing a cholesterol-lowering effect [38]. Considering this, Poles should be encouraged to increase their nut consumption and improve their dietary habits, which are far from the recommended for the prevention of cardiovascular diseases [45, 46]. Regarding individual dietary sources of total plant sterols, canola oil and white bread predominated, followed by soft margarine. Similar to a Chinese study, canola oil was the main provider of plant sterols among vegetable fats and oils [47].

As in the study of EPIC-Norfolk population [35], women in the WOBASZ survey had a higher plant sterol density than men. Interestingly, when converted per 1000 kcal, the total plant sterol content did not differ from the values obtained in the EPIC-Norfolk study. For men and women in our study, the amount of plant sterols was 141.0 mg and 154.2 mg, respectively, and in the EPIC-Norfolk study, for men it was 137.33 mg and for women 152.4 mg/day.

4.1. Limitations

This study used single 24 h recall as a tool to measure food intake, which is an appropriate method for large-scale studies. However, 24 h recall does not account for variability in food intake and may not describe a typical diet.

Some plant sterol values in this study may have been underestimated, because only three major sterols (sitosterol, campesterol, and stigmasterol) are typically included in the totals, despite the contribution of other sterols. Although the compiled database facilitated the calculation of plant sterols, there are some shortcomings due to the lack of data for individual plant sterols. This is mainly due to the fact that the literature data do not provide information on the content of plant sterols in certain food products. Moreover, there are no specific data on the composition of plant sterols in enriched margarine, which is related, among other things, to proprietary manufacturing technologies. In addition, since a small percentage of study participants consumed phytosterol-enriched margarine, they were not included in the calculation of dietary plant sterols.

5. Conclusions

This study found that the database of plant sterols facilitates the calculation of plant sterols in the typical Polish diet, and the results are comparable to those of other studies,
despite different methodologies of nutritional assessment and slightly different databases. The main sources of dietary plant sterols, which are cereals, fats, vegetables, and fruits, do not differ from the data for other populations. This study confirmed the observations of other research that women’s diets may have a higher plant sterol density compared to men.

*In the total and each food category, individual food products with the strongest impact on the β-sitosterol intakes were only listed.

**Table 4.** Contributions of food categories and individual food products to campesterol intake (CAMP), listed according to diminishing order of contribution.
## Contribution to CAMP (%)

| Major sources (%) contribution* | Contribution to CAMP (%) |
|---------------------------------|---------------------------|
| oils (35.50) including:         |                           |
| canola oil (34.48), sunflower oil (0.94), soybean oil (0.06), olive oil (0.01), soft margarines (8.58), mayonnaise (1.81) | 46.30 |
| oils (33.61) including:         |                           |
| canola oil (32.26), sunflower oil (1.21), soybean oil (0.11), olive oil (0.01), soft margarines (7.60), mayonnaise (1.94) | 43.47 |
| oils (34.60) including:         |                           |
| canola oil (33.43), sunflower oil (1.07), soybean oil (0.08), olive oil (0.01), soft margarines (8.11), mayonnaise (1.87) | 44.95 |

## Cereals

| Contribution to CAMP (%) | mg/day (mean ± SD) |
|--------------------------|--------------------|
|                          | 23.34 ± 13.00      |
|                          | 15.09 ± 8.65       |
|                          | 18.79 ± 11.57      |

## Vegetables

| Contribution to CAMP (%) | mg/day (mean ± SD) |
|--------------------------|--------------------|
|                          | 3.06 ± 3.90        |
|                          | 3.04 ± 3.75        |
|                          | 3.04 ± 3.81        |

## Cookies, cakes

| Contribution to CAMP (%) | mg/day (mean ± SD) |
|--------------------------|--------------------|
|                          | 2.99 ± 6.69        |
|                          | 3.00 ± 5.95        |
|                          | 2.99 ± 6.30        |

## Coffee

| Contribution to CAMP (%) | mg/day (mean ± SD) |
|--------------------------|--------------------|
|                          | 2.87 ± 3.41        |
|                          | 3.37 ± 3.26        |
|                          | 3.15 ± 3.33        |
|          | mg/day (mean ± SD) | Contribution to CAMP (%) |
|----------|--------------------|--------------------------|
| **Fruits** |                    |                          |
|          | 1.38 ± 2.53        | 1.99                     |
|          | 1.63 ± 2.42        | 3.21                     |
|          | 1.52 ± 2.47        | 2.57                     |
|          | **Major sources**  |                          |
|          | raw fruits (1.98) including: |                        |
|          | apples (0.51), bananas (0.42), grapes (0.22), mandarins (0.21), plums (0.16), oranges (0.11) |                        |
|          | raw fruits (3.20) including: |                        |
|          | apples (0.72), bananas (0.64), grapes (0.40), mandarins (0.34), oranges (0.24), plums (0.23) |                        |

|          | 1.36 ± 0.36        | 2.67                     |
|          | 1.62 ± 1.62        | 2.74                     |
| **Total campesterol intake** | 69.16 ± 47.68       | 100                      |
|          | 50.83 ± 33.38      | 100                      |
|          | 59.06 ± 41.44      | 100                      |

*In the total and each food category, individual food products with the strongest impact on the total campesterol intakes were only listed.
Table 5. Contributions of food categories and individual food products to stigmasterol intake (STIG), listed according to diminishing order of contribution

| Food categories | Men          | Women         | All          |
|-----------------|--------------|---------------|--------------|
|                 | N=2554       | N=3136        | N=5690       |
| Coffee          | 5.64 ± 6.70  | 6.62 ± 6.40   | 6.18 ± 6.55  |
| Contribution to STIG (%) | 21.41       | 28.53         | 25.10        |
| Vegetables      | 6.00 ± 5.63  | 5.49 ± 5.34   | 5.72 ± 5.48  |
| Contribution to STIG (%) | 22.76       | 23.66         | 23.22        |
| Major sources  | raw vegetables (17.15) including: tomatoes (4.48), beets (2.02), cucumbers (1.83), carrots (1.64), parsley (1.89), green beans (1.52), lettuce (1.17), celery (1.12) | raw vegetables (18.60) including: tomatoes (4.76), beets (1.79), cucumbers (1.81), carrots (1.96), parsley (1.88), green beans (2.21), lettuce (1.31), celery (1.04) | raw vegetables (17.90) including: tomatoes (4.63), beets (1.90), cucumbers (1.82), carrots (1.80), parsley (1.88), green beans (1.88), lettuce (1.24), celery (1.08) |
| Fats            | 5.02 ± 5.79  | 3.44 ± 3.97   | 4.15 ± 4.93  |
| Contribution to STIG (%) | 19.05       | 14.84         | 16.85        |
| Major sources  | soft margarines (13.90), oils (3.69), mixed fats (0.79), mayonnaise (0.63) | soft margarines (9.91), oils (3.80), mixed fats (0.52), mayonnaise (0.56) | soft margarines (11.82), oils (3.75), mixed fats (0.65), mayonnaise (0.60) |
| Cereals         | 3.91 ± 2.43  | 2.60 ± 1.93   | 3.19 ± 2.26  |
| Contribution to STIG (%) | 14.83       | 11.18         | 12.93        |
| Major sources  | wheat bread (8.49), rolls (2.69), rye bread (2.44), cereals (0.47) | wheat bread (4.62), rolls (2.29), rye bread (2.69), cereals (0.84) | wheat bread (6.48), rolls (2.57), rye bread (2.48), cereals (0.66) |
| Chocolate products | 1.66 ± 6.00  | 1.51 ± 5.22   | 1.58 ± 5.59  |
| Contribution to STIG (%) | 6.29        | 6.52          | 6.40         |
| Legumes         | 1.47 ± 7.23  | 0.99 ± 4.86   | 1.21 ± 6.04  |
| Contribution to STIG (%) | 5.58        | 4.28          | 4.91         |
|                  | mg/day (mean ± SD) | Contribution to STIG (%) |
|------------------|--------------------|--------------------------|
| **Fruits**       |                    |                          |
|                  | 0.82 ± 1.71        | 3.13                     |
|                  | 1.00 ± 1.88        | 4.29                     |
|                  | 0.92 ± 1.81        | 3.73                     |
| Major sources    | raw fruits (3.12)   |                          |
|                  | including:         |                          |
|                  | bananas (1.33),    |                          |
|                  | apples (0.37),     |                          |
|                  | nectarines (0.27), |                          |
|                  | plums (0.26),      |                          |
|                  | peaches (0.25)     |                          |
|                  | raw fruits (4.28)   |                          |
|                  | including:         |                          |
|                  | bananas (1.68),    |                          |
|                  | apples (0.44),     |                          |
|                  | nectarines (0.33), |                          |
|                  | plums (0.32),      |                          |
|                  | peaches (0.53)     |                          |
|                  | raw fruits (3.72)   |                          |
|                  | including:         |                          |
|                  | bananas (1.68),    |                          |
|                  | apples (0.40),     |                          |
|                  | nectarines (0.30), |                          |
|                  | plums (0.29),      |                          |
|                  | peaches (0.40)     |                          |
| **Potatoes**     | 0.73 ± 0.72        | 2.77                     |
|                  | 0.52 ± 0.53        | 2.22                     |
|                  | 0.61 ± 0.63        | 2.48                     |
| **Cookies, cakes** | 0.57 ± 1.62        | 2.17                     |
|                  | 0.61 ± 1.44        | 2.61                     |
|                  | 0.59 ± 1.52        | 2.40                     |
| **Other food products** | 0.54              | 2.01                     |
|                  | 0.44               | 1.88                     |
|                  | 0.48               | 1.98                     |
| **Total stigmasterol intake** | 26.36 ± 16.02          |                          |
|                  | 23.22 ± 12.94      |                          |
|                  | 24.63 ± 14.49      |                          |

*In the total and each food category, individual food products with the strongest impact on the total stigmasterol intakes were only listed.*
