ABSTRACT

The evolution of a solar flare accelerated non-thermal electron population and associated plasma emission is considered in collisional inhomogeneous plasma. Non-thermal electrons collisionally evolve to become unstable and generate Langmuir waves, which may lead to intense radio emission. We self-consistently simulated the collisional relaxation of electrons, wave-particle interactions, and nonlinear Langmuir wave evolution in plasma with density fluctuations. Additionally, we simulated the scattering, decay, and coalescence of the Langmuir waves which produce radio emission at the fundamental or the harmonic of the plasma frequency, using an angle-averaged emission model. Long-wavelength density fluctuations, such as are observed in the corona, are seen to strongly suppress the levels of radio emission, meaning that a high level of Langmuir waves can be present without visible radio emission. Additionally, in homogeneous plasma, the emission shows time and frequency variations that could be smoothed out by density inhomogeneities.

Key words. Sun: particle emission, Sun: radio emission

1. Introduction

During solar flares, efficient acceleration of electrons in coronal loops is often observed. Such non-thermal electrons produce several radiation signatures, in particular hard X-rays (HXR), and radio emissions. These signatures are a valuable diagnostic for the properties of non-thermal electron populations. HXR emission is produced by collisional bremsstrahlung in the dense plasma of loop footpoints, and is particularly useful because the coronal plasma is optically thin to these wavelengths, and the cross-section for emission well known. Gyrosynchrotron emission (gyroemission from mildly relativistic particles) can produce strong continuum radio emission at GHz frequencies in regions of high magnetic field, while coherent emission mechanisms can produce intense radio bursts in some circumstances.

In particular, as noted by Emslie & Smith (1984), Hamilton & Petsiari (1987) fast electrons in dense plasma can produce Langmuir wave turbulence because of collisional evolution, and this can lead to intense plasma radio emission due to the large number of non-thermal electrons in flares. This collisional relaxation is the mechanism we consider here. For emission at the harmonic of the plasma frequency, resulting from the coalescence of two counter propagating Langmuir waves, a simple analytical estimate shows that this process should saturate at a brightness temperature equal to the brightness temperature of the Langmuir waves, therefore often reaching several orders of magnitude over the thermal level and thus easily visible.

On the other hand, Langmuir waves are known to be strongly affected by fluctuations in plasma density. Spreading of Langmuir waves in angle because of elastic scattering by density fluctuations was considered by e.g. Nishikawa & Ryutov (1976) and Muschietti et al. (1985) and found to suppress the beam-plasma interaction. A similar result for beam-aligned density fluctuations was found in our previous work (Ratcliffe et al. 2012). Moreover, Langmuir waves generated in non-uniform plasma can be shifted to lower wave numbers (higher phase velocities) and re-absorbed, leading to efficient acceleration of the tail of energetic electrons. A relatively high level of Langmuir waves can strongly affect the electron distribution above ~20 keV and lead to substantial over-estimation of electron number and energy in flares when simple collisional relaxation is assumed (Kontar et al. 2012). This self-acceleration of the electron tail is particularly efficient when the timescale of Langmuir wave friction is similar to the timescale of Langmuir wave generation (Ratcliffe et al. 2012) and is evident in 3D PIC simulations in magnetised plasma (Karlicky & Kontar 2012).

Thus it appears that density fluctuations can suppress the Langmuir wave generation from an electron population, and therefore allow for the existence of fast electrons without plasma radio emission. However, it still remains unclear whether a high level of Langmuir turbulence necessitates strong plasma emission in collisional flaring plasma, since a density gradient acting on Langmuir waves has already been found by Kontar & Pécseli (2002) to suppress Langmuir wave decay, potentially allowing the production of Langmuir waves without their conversion into radio emission. Addressing this problem requires detailed numerical simulations, because although the processes involved in the emission are qualitatively known (e.g. Ginzburg & Zhelezniakov 1958, Sturrock 1964, Zheleznyakov & Zaitsev 1970), an analytical treatment is not possible. Such numerical simulations are often employed for calculations applied to type III bursts (e.g. Li et al. 2008, Tsiklauri 2011).

Here we consider the plasma emission from accelerated electrons in a dense coronal loop. We self-consistently solve the problem of relaxation of a non-thermal electron population taking Langmuir wave excitation, absorption, and weakly-nonlinear
Plasma has an exponential density profile of scale height for Langmuir waves and ion-sound waves in Sections 2.2 and 2.3, respectively. The basic equations for electromagnetic emission are in Section 2.4 with the emission at the fundamental of the plasma frequency treated in Section 2.5 and the harmonic in Section 2.6. Finally, Section 2.7 addresses the considerations of propagation and absorption of electromagnetic emission. We note that the dynamics of electrons, Langmuir waves and ion-sound waves produced from Langmuir wave decay are all approximately one-dimensional. On the other hand, the equations for Langmuir wave conversion into electromagnetic emission are not, and are treated here using an angle-averaged approximation, described briefly below.

2.1. Non-thermal electron evolution

We describe the electrons using their distribution function $f(v, t) \mathrm{[cm}^{-3}] \mathrm{[cm}^{-3}]$, which is normalised so that

$$\int_{-\infty}^{\infty} f(v, t) \, dv = n_e + n_b, \quad (1)$$

where $n_e$ is the density of the background plasma, and $n_b$ that of non-thermal electrons, and the Langmuir waves by their spectral energy density as a function of wavenumber $k$, $W(k, t) \mathrm{[erg cm}^{-2}]$, where

$$\int_{k_{lo}}^{k_{hi}} W(k, t) \, dk = E_L, \quad (2)$$

is the total energy density of the waves in $\mathrm{erg cm}^{-3}$ and $k_{lo}$, $k_{hi}$ are the wave numbers of the fundamental and the harmonic of propagation and absorption of electromagnetic emission. We have

$$\frac{\partial f(v, t)}{\partial t} = \frac{4\pi^2 e^2}{m_e^2} \frac{\partial}{\partial v} \left( \frac{W(k, t)}{v} \frac{\partial f(v, t)}{\partial v} \right) + \Gamma \frac{\partial}{\partial v} \left( \frac{f(v, t)}{v^2} + \frac{v^2}{2} \frac{\partial f(v, t)}{\partial v} \right), \quad (3)$$

with $\Gamma = 4\pi e^2 n_e \ln \Lambda / m_e^2$ and $\ln \Lambda$ the Coulomb logarithm, approximately 20 in the solar corona.

The first term on the RHS of this equation describes emission and absorption of Langmuir waves by the electrons [Drummond & Pines 1964; Vedenov et al. 1962] with additional terms describing the effects of collisions. We note that the dynamics of electrons, Langmuir waves and ion-sound waves produced from Langmuir wave decay are all approximately one-dimensional. On the other hand, the equations for Langmuir wave conversion into electromagnetic emission are not, and are treated here using an angle-averaged approximation, described briefly below.

2. A model for electron and Langmuir wave evolution, and plasma radio emission

We consider a dense coronal loop embedded in the coronal plasma, as shown in Figure 1. The electron density is the combination of a constant density background plus small magnitude, long wavelength random density fluctuations. The evolution of a non-thermal electron population is considered in the collisional region, with the electron distribution, and all wave distributions, assumed not to depend on position within the source volume. The electron beam-plasma system is self-consistently treated taking into account the effects of non-uniform plasma density, plasma collisionality, non-linear wave-wave processes and the production of electromagnetic radio emission near the plasma frequency and its harmonic.

All of these processes are interrelated, and therefore simulated simultaneously. The equations describing the evolution of the electron distribution are given in Section 2.1 and those for Langmuir waves and ion-sound waves in Sections 2.2 and 2.3, respectively. The basic equations for electromagnetic emission are in Section 2.4 with the emission at the fundamental of the plasma frequency treated in Section 2.5 and the harmonic in Section 2.6. Finally, Section 2.7 addresses the considerations of propagation and absorption of electromagnetic emission. We note that the dynamics of electrons, Langmuir waves and ion-sound waves produced from Langmuir wave decay are all approximately one-dimensional. On the other hand, the equations for Langmuir wave conversion into electromagnetic emission are not, and are treated here using an angle-averaged approximation, described briefly below.

2.1. Non-thermal electron evolution

We describe the electrons using their distribution function $f(v, t) \mathrm{[cm}^{-3}] \mathrm{[cm}^{-3}]$, which is normalised so that

$$\int_{-\infty}^{\infty} f(v, t) \, dv = n_e + n_b, \quad (1)$$

where $n_e$ is the density of the background plasma, and $n_b$ that of non-thermal electrons, and the Langmuir waves by their spectral energy density as a function of wavenumber $k$, $W(k, t) \mathrm{[erg cm}^{-2}]$, where

$$\int_{k_{lo}}^{k_{hi}} W(k, t) \, dk = E_L, \quad (2)$$

is the total energy density of the waves in $\mathrm{erg cm}^{-3}$ and $k_{lo}$, $k_{hi}$ are the wave numbers of the fundamental and the harmonic of propagation and absorption of electromagnetic emission. We have

$$\frac{\partial f(v, t)}{\partial t} = \frac{4\pi^2 e^2}{m_e^2} \frac{\partial}{\partial v} \left( \frac{W(k, t)}{v} \frac{\partial f(v, t)}{\partial v} \right) + \Gamma \frac{\partial}{\partial v} \left( \frac{f(v, t)}{v^2} + \frac{v^2}{2} \frac{\partial f(v, t)}{\partial v} \right), \quad (3)$$

with $\Gamma = 4\pi e^2 n_e \ln \Lambda / m_e^2$ and $\ln \Lambda$ the Coulomb logarithm, approximately 20 in the solar corona.

The first term on the RHS of this equation describes emission and absorption of Langmuir waves by the electrons [Drummond & Pines 1964; Vedenov et al. 1962] with additional terms describing the effects of collisions. We note that the dynamics of electrons, Langmuir waves and ion-sound waves produced from Langmuir wave decay are all approximately one-dimensional. On the other hand, the equations for Langmuir wave conversion into electromagnetic emission are not, and are treated here using an angle-averaged approximation, described briefly below.
Langmuir wave generation will tend to flatten this reverse slope, while collisions continue to restore it, leading to a plateau in the electron distribution with slowly decreasing height as the electrons thermalise.

2.2. Langmuir wave evolution

The electron beam generates Langmuir waves (denoted L) with wavenumbers parallel to the direction of propagation. These may then be backscattered by two processes \( L \leftrightarrow L' + s \) involving ion-sound waves (denoted s) and \( L + i \leftrightarrow L' + i' \) where \( i, i' \) denote initial and final states of a plasma ion. The relative importance of these two processes depends strongly on the ratio of electron and ion temperatures, \( T_e/T_i \), which can vary between \( \sim 2 \) and \( \sim 0.1 \) in the corona and solar wind (e.g. Gurnett et al. 1979; Newbury et al. 1998). Generally, Langmuir scattering is important in plasma with \( T_i \geq T_e \), where ion-sound waves are very strongly damped, and the decay involving ion-sound waves when the ion temperature is lower (e.g. Cairns 2000).

The governing equation for the spectral energy density of Langmuir waves is (Drummond & Pines 1964; Vedenov et al. 1964; Zelenskyakov & Zaitsev 1970)

\[
\frac{\partial W(k, t)}{\partial t} = \frac{\omega_{pe}^2 m_e}{4 \pi n_e} v \ln \left( \frac{v}{v_T} \right) f(v, t) + \frac{\pi \omega_{pe}^3}{n_e k^3} W(k, t) \frac{\partial f(v, t)}{\partial v} - \gamma_c W(k, t) + S_{\text{damp}}(W(k, t)) + S_{\text{i}}(W(k, t)),
\]

where \( \gamma_c = \frac{1}{\sqrt{2 \pi M_i} v_T} \), \( \gamma_c \approx \Gamma/(4 \pi^3) \), and \( k = \omega_{pe}/v \). The first and second terms on the RHS are the spontaneous and stimulated emission of Langmuir waves by electrons. These terms are derived in the weak-turbulence limit,

\[
E_L/(n_e k_i T_i) \ll (k/k_D)^2,
\]

so that the energy density of Langmuir waves is much less than the energy density of surrounding plasma.

Collisional damping of Langmuir waves (e.g. Lifshitz & Pitaevskii 1981; Melrose 1980a) is given by the third term on the RHS in Equation 4, while the fourth describes Langmuir wave damping in wavenumber space due to long-wavelength plasma density fluctuations. For a plasma density which is given by \( n(x, t) = n_0(1 + \tilde{n}(x, t)) \), the sum of a background and small fluctuations \( \tilde{n} \ll 1 \) with length scales far larger than the Debye length, the diffusion coefficient is (Ratcliffe et al. 2012)

\[
D(k) = \omega_{pe}^2 k^3/2 \left[ \frac{\tilde{n}(k^2)}{v_0^2} \right]^{3/2} \left[ 1 + \frac{v_s(k^2)}{v_0^2} \right]^{-3/2},
\]

for random density fluctuations with characteristic velocity \( v_0 \), wavenumber \( q_0 \) and RMS (root mean square) fluctuation level \( \sqrt{\langle \tilde{n}^2 \rangle} \), and \( v_s = 3v_T^2 k/\omega_{pe} \) the group velocity of Langmuir waves.

The two terms labelled S describe the scattering and decay of Langmuir waves by the processes \( L+i \leftrightarrow L'+i' \) and \( L \leftrightarrow L'+s \) where \( i, i' \) are an initial and scattered plasma ion and \( s \) denotes an ion-sound wave. Both of these produce back-scattered (negative wavenumber) Langmuir waves. The general expressions describing these processes are standard (e.g. Melrose 1980a; Tsytovich 1995), and have been rewritten here under the assumption that fast-electron generated Langmuir waves propagate approximately parallel to the generating electrons and therefore the ambient magnetic field. Hereafter, we omit the explicit time dependence of the spectral energy densities for clarity of notation.

Langmuir wave scattering by ions is described by

\[
S_{\text{i}}(W(k)) = \int dk_L \frac{\alpha_{\text{i}}}{|k-k_L|} \exp \left( -\frac{(\omega_{li} - \omega_L)^2}{2(k-k_L)^2 v_{T_i}^2} \right) \left[ -\frac{1}{k_L T_i} \omega_{li} - \omega_L \right] W(k_L) W(k)
\]

where \( k, k_L, \omega_{li}, \omega_L \) are the wavenumber and frequency of the initial and scattered Langmuir waves, and

\[
\alpha_{\text{i}} = \frac{\sqrt{2} \pi \omega_{pe}^2}{4 \pi n_e k_B T_i}. \tag{7}
\]

For a given initial Langmuir wavenumber, \( k \), we have two possible processes, namely \( L \rightarrow L' + s \) and \( L + s \rightarrow L' \). The wavenumbers of the resulting Langmuir wave, \( k_L, k_{L'} \), respectively, and the participating ion-sound wave, \( k_s \), are found from simultaneous solution of the equations of energy conservation (encoded by the delta functions in Equation 9), and momentum conservation, given by \( k_L = k - k_s \) and \( k_{L'} = k + k_s \) for the two processes respectively. For example, for the process \( L \rightarrow L' + s \) we find \( k_L \approx -k \), and \( k_s \approx 2k \), and the initial Langmuir wave is backscattered. More precisely, we have \( k_L = -k + \Delta k \) with the small increment \( \Delta k = 2 \sqrt{\langle \tilde{n}(k^2) \rangle} / (3 v_B) \). Thus re-peated scatterings tend to accumulate Langmuir waves at small wavenumbers.
2.3. Ion-sound wave evolution

The evolution of the ion-sound wave distribution is given by (e.g. Melrose 1980b; Tsytovich 1995)

\[
\frac{\partial W_s(k)}{\partial t} = -\gamma_s(k) W_s(k) - \alpha_s(\omega_s^2) \int \left( \frac{W(k_s)}{\omega_s^2 - \omega_k^2} - \frac{W(k_{s'} \omega_s^2 - \omega_{k_{s'}}^2} \right) \times \delta(\omega_{k_s} - \omega_k, \omega_{k_{s'}} - \omega_{k_{s'}}') dk_{s'} dk_{s''}.
\]

(11)

The second term here is analogous to Equation 9 describing the interaction of an ion-sound wave at wavenumber \(k\) with a Langmuir wave at wavenumber \(k_L\), producing a Langmuir wave at wavenumber \(k_L'\). Again, these participating wavenumbers are found from simultaneous solution of energy (frequency) and momentum (wavenumber) conservation. The first term is Landau damping of the waves, with coefficient

\[
\gamma_s(k) = \frac{v_T^4}{2} \left( \frac{\omega_s}{\omega_k} \right) \left( \frac{1}{v_T} + \frac{1}{v_{T,\nu}} \right) \exp \left( -\frac{v_k^2}{2v_T^2} \right).
\]

(12)

Using the definitions of \(v_{\nu}, v_{T,\nu}, v_T\), we see that the ion contribution dominates and \(\gamma_s = \omega_s^2/(3 + T_e/T_i)^{1/2} \exp(-[3 + T_e/T_i])\), which is of the order of \(\omega_s^2\) unless \(T_i \ll T_e\), which is therefore a condition leading to high levels of ion-sound waves.

2.4. Electromagnetic emission

We describe the radio emission in terms of its brightness temperature, \(T_B\), which is defined from the Rayleigh-Jeans law for the radiation intensity as function of frequency by \(I(\nu) = 2\nu^2k_BT_B/c^2\). We consider radiation at positive and negative wavenumber, the former propagating outwards from the Sun, along the direction of the beam propagation and the latter propagating backwards, and thus consider brightness temperature averaged over the corresponding hemisphere.

For thermal radiation, the definition of the brightness temperature gives \(T_B = T_T\), the plasma temperature. This radiation level is maintained by the thermal bremsstrahlung emission from the plasma particles, and by a corresponding damping. Kirchoff’s law says that these must be related by \(P(k) = \gamma_BT_T\) for \(P\) the thermal emission rate, and \(\gamma_d\) the damping, in order that the two balance to give the thermal radiation level. Thus, from the bremsstrahlung damping rate,

\[
\gamma_d(k) = \frac{\omega_{pe}^2}{\omega(k)^2},
\]

(13)

we can derive the thermal emission rate, or vice versa.

For emission described in terms of its brightness temperature we therefore have simply

\[
\frac{dT_T(k_T)}{dt} = \gamma_dT_T - \gamma_dT_T(k_T) - \frac{v_T}{d}T_T(k_T) + S(p_{ion}(k_T) + S(m_{ion}(k_T) + S(p_{harm}(k_T)
\]

(14)

where the first term is the thermal emission rate and the second term is the collisional damping. The third term, in which \(v_T^2\) is the group velocity for electromagnetic waves, given by \(v_T^2 = c^2k_T/\omega_T\), and \(d\) is the source region size, describes the escape of radiation from the source region using a simple “leaky box” model. The waves propagate at velocity \(v_T\) and so over a time \(dt\), we will lose a fraction given by \(v_T^2/v_T^2/d\) from the source region. Finally, we have the source terms, describing the production of radio emission from Langmuir waves, either at the fundamental, near \(\omega_{pe}\) or the harmonic near \(2\omega_{pe}\). These are derived in the following two subsections.

2.5. Fundamental electromagnetic source terms

The processes for emission at the fundamental are \(L + i t + s\) where \(L, s\) are Langmuir and ion-sound waves, and \(t\) is an EM wave, and \(L + i t + s + t'\) for \(i, t'\) an initial and scattered plasma ion. The probability of both processes (e.g. Tsytovich 1995) is maximised for an EM wave with wavevector perpendicular to the initial Langmuir wave. Assuming the beam-generated Langmuir waves have some small angular spread in wavenumber space, covering a solid angle of \(\Delta\Omega\), and further assuming that they are uniform within this spread, fundamental emission will be produced approximately isotropically. The larger the solid angle \(\Delta\Omega\), the better this assumption becomes.

The source term entering Equation 13 for fundamental emission by the processes \(L + s + i \rightarrow t + s + t'\) is again based on the general expressions in (e.g. Melrose 1980b; Tsytovich 1995). Rewriting in terms of the hemisphere-averaged brightness temperature, given by

\[
T_T(k_T) = \frac{W_T(k_T)}{2\pi k_BT_T^2}
\]

(15)

for \(W_T(k_T)\) the EM wave spectral energy density, and using the assumptions described in the previous paragraph gives

\[
S_{p_{ion}}(k_T) = \frac{\pi\omega_{pe}^2v_T(1 + \frac{v_T^2}{d})}{24\pi^2k_BT_T^2} \times dk_L
\]

\[
\left\{ \frac{W_s(k_s)}{\omega_{s}^2 - \omega_{k_s}^2} - \frac{W_L(k_L)}{\omega_{k_L}^2} \right\} \times \frac{\omega_{s}^2}{\omega_{k_s}^2} + \frac{W_L(k_L)}{\omega_{k_L}^2} \right\}
\]

\[
\delta(\omega_{k_s} - \omega_{k_s'} - \omega_{k_L} - \omega_{k_{s'}})
\]

\[
\frac{W_s(k_s)}{\omega_{s}^2 - \omega_{k_s}^2} - \frac{W_L(k_L)}{\omega_{k_L}^2} \right\} \times \frac{\omega_{s}^2}{\omega_{k_s}^2} + \frac{W_L(k_L)}{\omega_{k_L}^2} \right\}
\]

\[
\delta(\omega_{k_s} - \omega_{k_s'} - \omega_{k_L} - \omega_{k_{s'}})
\]

(16)

where the participating wavenumbers are obtained from energy and momentum conservation. However, in this case the momentum conservation condition must be obtained from the 3-D description of the process. Using our assumption that the EM emission occurs approximately perpendicular to the initial Langmuir wave, the wavenumbers \(k_s, k_s', k_L, k_{s'}\) form a right-triangle and thus we find that \(k_s'^2 = k_s^2 + k_L^2\).

Similarly, direct ion scattering, \(L + i t + t' + s\), is described by

\[
S_{p_{ion}}(k_T) = \frac{\sqrt{\pi}\omega_{pe}^2}{4k_BT_T^2v_T} \times \left\{ \frac{\omega_{s}^2}{\omega_{k_s}^2} + \frac{W_L(k_L)}{\omega_{k_L}^2} \right\}
\]

\[
\delta(\omega_{k_s} - \omega_{k_s'} - \omega_{k_L} - \omega_{k_{s'}})
\]

(17)

where again \(\Delta\Omega\) is the angular spread of the Langmuir waves, and we have assumed again that the EM emission occurs approximately perpendicular to the initial Langmuir wave. The momentum change between initial and final waves is absorbed by the plasma ions, which are assumed to be thermal, as in the case of Langmuir wave scattering by ions considered above.
2.6. Harmonic electromagnetic emission source terms

Emission at the harmonic of the plasma frequency occurs due to the coalescence of two Langmuir waves, \( L + L' \rightarrow t \). Calculating an angle-averaged emission probability is complicated, because the emission probability depends directly on the participating wavenumbers, \( k_1, k_2 \) for the Langmuir waves, and \( k_T \) for the EM wave, and the magnitudes of these depend on the geometry of the coalescence. In early models of emission, the “head-on-approximation” (HOA), where the Langmuir waves are almost antiparallel was suggested, which allows the emission probability to be greatly simplified. However, this assumption leads to significant overestimates of the emission rate, particularly at small wavenumbers (e.g. Melrose & Stenhouse [1979]), as it assumes that the product electromagnetic wavenumber is far smaller than the initial Langmuir wavenumber, \( k_T \ll k_L \), whereas in fact \( k_T \approx (\sqrt{3}v/c)k_{Dw} \) which is often comparable to \( k_L \).

Therefore the Langmuir waves cannot coalesce exactly head-on, but rather at an angle less than \( \pi \). Rather than specify this angle, which will depend on the values of \( k_1 \) and \( k_T \), we specify the angle between one of the initial Langmuir waves and the final EM wave. The emission probability is quadrupolar (Tsytovich [1970]), with a maximum when this angle is \( \pi/4 \), assuming both waves have the same sign for the beam-parallell-component.

We therefore use this value to solve the wavenumber and frequency matching equations. We then average the probability over its FWHM using these wavenumber values. For Langmuir waves which are uniform over a solid angle (in wavenumber space) of \( \Delta \Omega \geq \pi/20 \) and for \( \omega_{EM} \geq 2.01\omega_{pe} \), the majority of Langmuir waves can participate in coalescence with the specified geometry, and we have an accurate approximation to the angle-averaged emission rate.

As in the case of fundamental emission, we use the general expressions of (e.g. Melrose [1980], Tsytovich [1995]), convert to brightness temperature using Equation [13] and use our assumed emission geometry. The resulting source term for harmonic emission is

\[
S_{\text{harmonics}}^{\text{II}}(k_T) = \omega_{pe}^2 48m_e n_e v_T^2 \int dk_1 \left( \frac{k_1^2 - k_2^2}{4k_T^2} \right) \times
\]

\[
\frac{2\pi^2}{k_1 k_2 \Delta \Omega} W(k_1) W(k_2) T_x(k_T) \left( \frac{W(k_1)}{k_1^4} + \frac{W(k_2)}{k_2^4} \right) \times
\]

\[
\delta(\omega_{k_1} + \omega_{k_2} - \omega_{k_T}) \times
\]

\[
\frac{2}{k_T \Omega} \omega_{pe}^2 \left( \frac{\omega_{pe}^2}{3v_T^2} + k_T^2 \cos^2 \left( \frac{\pi}{4} \right) - 2 \right),
\]

where \( k_1, k_2 \) are the wavenumbers of the forwards and backwards coalescing Langmuir waves respectively, \( \omega_{k_1}, \omega_{k_2} \) the corresponding Langmuir wave frequencies, and \( k_T, \omega_{k_T} \) the wavenumber and frequency of the EM wave. From energy and momentum conservation, described by the delta function and by \( k_1 + k_2 = k_T \) respectively, we have the conditions

\[
k_1 = \frac{1}{2} k_T \cos \left( \frac{\pi}{4} \right) + \frac{1}{2} \left( \frac{\omega_{pe}^2(\omega_{k_1}^2 - 2\omega_{pe}^2)}{3v_T^2} + k_T^2 \cos^2 \left( \frac{\pi}{4} \right) - 2 \right),
\]

considering only terms up to second order in \( k_T \), and using that \( \omega_{k_T} \approx 2\omega_{pe} \), and \( k_T^2 = k_1^2 + k_2^2 - 2k_1 k_2 \cos(\pi/4) \) under the angular assumptions described previously.

2.7. Propagation and absorption of radio emission

Finally, to relate the brightness temperature of radio emission within the source, given by the solution of Equation [14] to the observed flux we must consider the absorption of radiation during propagation. Collisional absorption (inverse bremsstrahlung) with damping rate \( \gamma_d \) gives an optical depth of

\[
\tau = \int_0^\infty \frac{\gamma_d(x)}{v_f^2(x)} dx \tag{20}
\]

where \( v_f^2 = c(1 - \omega_{k_T}^2/\omega_e^2)^{1/2} \) is the group velocity for electromagnetic waves. Because this tends to zero as \( \omega \) tends to \( \omega_{pe} \), emission at the fundamental has a far larger optical depth than that at the harmonic.

For emission at a frequency \( \omega_0 \) we then have

\[
\tau(\omega_0) = \int_0^\infty dx \sqrt{\frac{2}{\pi}} \frac{e^{2} \ln \Lambda}{4v_f^2(x)} \left( \frac{\omega_{pe}^2(x)}{\omega_0^2 - \omega_{pe}^2(x)} \right) \tag{21}
\]

We assume isothermal plasma between source and observer, with an exponential density profile \( n_s(x) = n_0 \exp(-x/H) \), where \( x \) is the distance from the region of emission at density \( n_0 \), and \( H \) is the density scale height. The local plasma frequency is thus

\[
\omega_{pe}(x) = \omega_{pe}(0) \exp \left(-\frac{x}{2H} \right) \tag{22}
\]

From Equation [21] we find

\[
\tau(\omega_0) = \int_0^\infty dx \sqrt{\frac{2}{\pi}} \frac{e^{2} \ln \Lambda}{4v_f^2(x)} \left( \frac{\omega_{pe}^2(0) \exp \left(-\frac{x}{2H} \right)}{\sqrt{\omega_0^2 - \omega_{pe}^2(0) \exp \left(-\frac{x}{2H} \right)}} \right) \tag{23}
\]

This may be integrated to find

\[
\tau(\omega_0) = \sqrt{\frac{2}{\pi}} \frac{e^{2} \ln \Lambda H}{4v_f^2(x)} \left( \frac{1}{\omega_0^2} - \frac{1}{\omega_{pe}^2(0)} \left( \omega_0^2 + 0.5\omega_{pe}^2(0) \right) \right) \tag{24}
\]

where we have neglected the small term involving plasma frequency at 1AU.

The resulting escape fraction \( \exp(-\tau) \) is rather small for \( \omega_{pe}/(2\pi) \sim 1 \) GHz, and very dependent on the density scale height, \( H \), chosen. For the corona this is around \( 10^7 \) cm which gives a fraction of around 1/50 for harmonic emission, and below \( 10^{-7} \) for the fundamental. A scale height of \( 6 \times 10^7 \) cm gives again a very small result for the fundamental, and a value of 1/10 for the harmonic. Alternately, if the emission comes from a dense loop embedded in less dense background plasma, the escape fraction for both components may be increased (Karlinsky [1998]), although that for the fundamental remains very small.

The source size is calculated by assuming a linear size of \( 10^8 \) cm (e.g. Jeffrey & Kontar [2013]) at a distance of 1AU, which gives 0.2°. Then from the source brightness temperature, we may obtain the observed flux in sfu (Solar Flux Units, 1 sfu=10^{-19} erg s^{-1} cm^{-2} Hz^{-1}) using the definition of specific intensity, i.e. the Rayleigh-Jeans law, \( I(\nu) = 2\nu^2 k_0 T_{E}/c^2 \), where \( \nu \) is the frequency in Hz, and that for the flux, \( F(\nu) = I(\nu)\nu^2 \theta^2 \) where \( \theta \) is the angular radius of the source, giving \( \pi \theta^2 \) the solid angle covered by it. We assume the brightness temperature is constant throughout the source. Thus the observed flux, including absorption during propagation, is given by

\[
F(\nu) = 2k_0 T_E(\nu) \frac{\nu^2}{c^2} \pi \theta^2 \exp(-\tau) \tag{25}
\]

with the optical depth \( \tau \) given by Equation [24].
3. Numerical Results

3.1. Initial conditions

We take a plasma density of \( n_e \approx 10^{10} \text{ cm}^{-3} \), corresponding to a local plasma frequency of \( \nu_{pe} = \omega_{pe}/(2\pi) = 1 \text{ GHz} \), and a plasma temperature of \( T_e = 1 \text{ MK} \). The ion temperature \( T_i \) is either \( 0.5T_e \) or \( T_e \) in the cases below.

The initial electron distribution is a power law smoothly joined to the Maxwellian core, with velocity \( v_b \) and a power law index of \( \delta \) in energy space

\[
f(v, t = 0) = \frac{n_e}{\sqrt{2\pi} v_{Te}} \exp\left(-\frac{v^2}{2v_{Te}^2}\right) + \frac{2n_b}{\sqrt{2\pi} v_b} \Gamma(\delta) \left[ 1 + (v/v_b)^2 \right]^{-\frac{\delta}{2}}
\]

where \( \Gamma \) denotes the gamma function. We take a power law index of \( \delta = 4 \) (e.g. Dennison 1985) and a beam velocity of \( v_b = 10v_{Te} \). The low-energy turnover produced by the unit term in the square brackets precludes the divergence of the fast-electron component as \( v \) goes to zero. The effect on the velocities of interest for Langmuir wave generation are minimal.

The thermal Langmuir wave level is found by setting the LHS of Equation 26 to zero and balancing the thermal (first and third) terms on the RHS, giving

\[
W(k, t = 0) = \frac{k_B T_e}{4\pi^2} k^2 \ln\left(\frac{1}{k_{De}}\right) \left[ 1 + \frac{\ln k}{\ln k_{De}} \right] \exp\left(\frac{1}{k^2 k_{De}}\right)
\]

\[
= \frac{k_B T_e}{4\pi^2} k^2 \ln\left(\frac{1}{k_{De}}\right),
\]

with \( k_{De} = 1/k_{De} = v_{Te}/\omega_{pe} \). The initial level of ion-sound waves is thermal (Kontar et al 2012),

\[
W_i(k_s) = k_B T_e k^2 \ln\left(\frac{1}{k_{De}}\right) \frac{k^2}{k_{De}^2 + k_s^2}
\]

and the initial EM brightness temperature is thermal, \( T_F = T_e \).

3.2. Scattering by Ions

In plasma with equal ion and electron temperatures, \( T_i = T_e = 1 \text{ MK} \), ion-sound waves are strongly damped, and ion-scattering dominates the Langmuir wave backscattering. We take an initial beam as given by Equation 26 with a beam density of \( n_b = 10^{10} \text{ cm}^{-3} \). We note that this is for the initial power-law distribution. As collisional relaxation proceeds, a bump-on-tail distribution is produced, with a central velocity, density and width which vary over time due to continuing collisional losses. At this time, the majority of the beam electrons have thermalised, and so the level of Langmuir waves produced remains within the limits of weak-turbulence theory. In this section, we simulate electron-Langmuir wave evolution as given by Equations 3 and 4 and radio emission as in Equation 14. We omit the terms involving ion-sound waves (Equations 9 and 10) as the sound-wave damping rate is \( \gamma_S = \omega_S \), i.e. the waves are damped over a timescale of less than one period, and the weak-turbulence equations will not accurately describe the behaviour (e.g. Melrose 1980b; Tsytovich 1995). Instead we consider the process of scattering by plasma-ions only.

Figure 2 shows, for the case of homogeneous plasma, the resulting electron distribution, the Langmuir and ion-sound wave spectral energy densities, normalised to \( k_B T_e k^2/(4\pi^2) \) (see Equation 27), and the fundamental and harmonic radiation brightness temperatures. The fundamental emission reaches a brightness temperature of around \( T_F = 10^7 \text{ K} \), while the harmonic emission can reach \( T_F = 10^{11} \text{ K} \). These are the in-source brightness temperatures, whereas the observable brightness temperature will be reduced by a factor of \( \exp(-\tau) \), with \( \tau \) the optical depth as in Equation 24. As noted above this means fundamental emission at these levels will not be observable, and the harmonic component will be reduced by around an order of magnitude. The dispersion relation for electromagnetic waves is\( \omega = (\omega_{pe} + c^2k^2)^{1/2} \) and so the wavenumber variation shown here will lead to emission at a small range of frequencies near \( \omega_{pe} \) and \( 2\omega_{pe} \).

Langmuir wave scattering by plasma ions is described by Equation 7. By taking the limit of \( v_i \ll v_{Te} \) in Equation 4, we find the RHS is proportional to \( d/dk(kW(k)) \) (as in Mel’Nik & Kontar 2003), and we therefore require locally positive gradient, \( d/dk(kW(k)) > 0 \) for the backscattered waves to grow. Backscattering can then produce new regions of positive slope in the forwards wave spectrum, as seen in Figure 2 and these each produce a peak in the backscattered spectrum, leading to the multiple peaked distribution seen at around 0.1 s, and the similar structure seen in the harmonic emission.

We now consider the effects of Langmuir wave diffusion in wavenumber due to density fluctuations, with coefficient \( D(k) \) given by Equation 6. The parameters of small-scale density fluctuations are unknown in the low corona. However, previous work (Ratcliffe et al. 2012) has shown that the most important factor for Langmuir wave evolution is the diffusive time-scale \( \tau_D \), which we define here as

\[
\tau_D = \frac{k_B^2}{D(k_b)},
\]

where \( k_b \) is the typical wavenumber of Langmuir waves in resonance with the reverse slope part of the electron distribution function. For a collisionally relaxing beam, this typical wavenumber varies over time, so we take the value at a time of 0.3s, \( k_b \approx 0.1k_{De} \). We set the characteristic velocity to approximately the sound speed, \( v_0 = 10^7 \text{ cm s}^{-1} \), and consider \( \tau_D \approx 0.24 \text{ s} \) and 0.05 s. To relate this \( \tau_D \) to the RMS
density fluctuation $\sqrt{\langle D^2 \rangle}$ we must assume a value for $q_0$, the characteristic wavenumber of fluctuations. For example, taking $q_0 = 6 \times 10^{-4}\,k_D$ corresponding to a length scale of 10 km, gives $\sqrt{\langle D^2 \rangle} = 6 \times 10^{-4}$ for $\tau_D = 0.24 \,s$. This may be compared with observations in the higher corona and solar wind, which show levels of the order $\sqrt{\langle D^2 \rangle} \sim 10^{-4}$ to $10^{-2}$ (Cronev1972, Smith & Sime 1979).

Figure 2 also shows the electron, Langmuir wave and ion-sound wave distributions and the fundamental and harmonic radio brightness temperature for $\tau_D \approx 0.24 \,s$. Significant spreading of the Langmuir waves is evident, with a decrease in the backscattered wave level and consequently in the brightness of electromagnetic emission.

Figures 3 and 4 show the Langmuir wave spectral energy density and observable radio flux, calculated using Equation 25 in sfu (Solar Flux Units, 1 sfu=10^{-10} erg s^{-1} cm^{-2} Hz^{-1}) for three cases of density fluctuations, with $\tau_D = 0.05, 0.24, 2.4$ as well as the homogeneous case. The small oscillations in radio wave energy seen between 0.2 and 0.4 s are a numerical effect probably due to the discrete wavenumber grid used in the simulation code. The calculated fluxes are a few to perhaps ten sfu while the duration of the simulated emission varies between approximately half a second for the homogeneous case down to around 0.1 s in the most inhomogeneous case. This duration is controlled by the Langmuir wave level, which in turn is controlled by the collisional relaxation of the electron beam.

Collisional relaxation also leads to the generation of Langmuir waves at smaller wavenumbers over time, which causes the emission to drift in frequency, in this case by approximately 50 MHz. Electromagnetic emission is more efficient at lower frequencies, and so the level of emission rises. This is seen clearly in the bottom panels of Figures 3 and 4 where we plot the total energy in Langmuir waves, $E_L$, backwards (negative wavenumber) Langmuir waves $E_L^B$ and harmonic electromagnetic emission $E_H$, all normalised to the thermal levels. Initially, the rise of the electromagnetic wave energy $E_H$ closely tracks the backscattered wave energy $E_L^B$. However, for the two moderately inhomogeneous cases (top right and bottom left panels), we see the continued increase of electromagnetic wave energy after the backscattered Langmuir wave energy has peaked, between 0.15 to 0.3 seconds.

The observable thermal radio emission from our source, with size $0.2^\circ$ and temperature $10^6 \,K$, including absorption, is approximately $10^{-2}$ sfu. In contrast, the average whole Sun radio emission at 2 GHz varies over the solar cycle between approximately 50 and 150 sfu, and so we take a reference value of 100 sfu at 2 GHz, scaling with frequency as in Smith & Sime (1979). In Figure 5 we show the time profile of observed emission in homogeneous plasma including this background, averaged over frequency bands $\nu$ to $\nu + \Delta\nu$. Figure 5 shows the result in homogeneous plasma for $\Delta\nu=1 \,MHz$ and 5 MHz and $\nu$ from 2.01 GHz to 2.05 GHz. The spiky nature of the emission in both time and frequency is evident. Figure 5 shows the fluxes for $\Delta\nu=5 \,MHz$ in homogeneous and inhomogeneous plasma. Inhomogeneity is seen to smooth out the time and frequency variations, as well as reducing the intensity of emission. The effects of absorption during propagation are illustrated in Figure 5 where we show density scale heights of $H = 10^8 \,cm$ and $6 \times 10^8 \,cm$, the latter giving a four-fold enhancement in the observed emission from the source.

### 3.3. Ion-sound wave scattering

For plasma with an electron temperature larger than the ion temperature, $T_e > T_i$, we can also consider the decay of Langmuir waves to an ion-sound wave, and a backscattered Langmuir wave, described by Equation 9. We take $T_i = 10^6 \,K$ and $T_e = 5 \times 10^7 \,K$, with other parameters as in the previous section to obtain Figure 6 which show the electron and wave distributions in inhomogeneous plasma with $\tau_D = 0.024 \,s$ and $\tau_D = 0.0024 \,s$ respectively. The level of backscattered Langmuir waves in these cases is far less affected by inhomogeneity than that due to ion-scattering alone, with complete suppression only for the shortest $\tau_D$. The harmonic radio emission we see is of similar magnitudes to that seen in the previous section, but covers a slightly wider range in $k$-space, and therefore frequency, at a given time. The fundamental emission is again much weaker than the harmonic.

### 4. Discussion and conclusions

The numerical results presented in Figures 2 and 8 show the tendency of plasma density inhomogeneities to suppress Langmuir wave backscattering. In Figure 7 we plot the peak backwards Langmuir wave spectral energy density for several cases of density fluctuations, in both equal temperature plasma and plasma with $T_i = 0.5T_e$. Both show a sharp decrease in backscattered level, but in the latter case this occurs only for much stronger inhomogeneity than the former. This is due to the relative efficiencies of the two backscattering processes, or equivalently their timescales. In general, the Langmuir wavenumber diffusion can suppress a process when $\tau_D$ is similar to the timescale of the process, as found in previous work (Ratcliffe et al 2012) in relation to the interaction of Langmuir waves with beam electrons.

In the cases shown here, the inhomogeneity is too weak to significantly suppress the beam-plasma interaction, although we do see some slight electron acceleration, due to the transfer of energy from slower to faster electrons by the wavenumber diffusion. Comparing Figure 8 with the homogeneous case in Figure 2, the latter displays a broadened plateau in the electron distribution around 20$\nu_\tau D$, where electrons have been accelerated. Stronger inhomogeneities, with $\tau_D > \tau_D$ the quasilinear time for beam-plasma interaction, can lead to significant electron distribution tail self-acceleration. Here, we have seen that plasma emission from such a beam would be suppressed at GHz frequencies.

In-source brightness temperatures of $10^{11} \,K$ were seen in homogeneous plasma, corresponding to an observed flux of the order of a few sfu, potentially observable against the quiet Sun background. Even a low level of inhomogeneities can reduce these values by an order of magnitude, while strong fluctuations suppress the emission to the thermal level. The level of density fluctuations as commonly observed in the corona (Cronev1972, Smith & Sime 1979) with $q_0^{-1} = 10 \,km$ leads to suppression of electromagnetic emission for RMS fluctuation magnitude of $\sqrt{\langle D^2 \rangle} \sim 7 \times 10^{-4}$ for equal temperature plasma, and $\sqrt{\langle D^2 \rangle} \sim 3 \times 10^{-3}$ in plasma with larger electron than ion temperature. Therefore we expect no observable plasma emission at these levels of inhomogeneity in the emission source.

To conclude, we have developed an angle-averaged emission model for fundamental and harmonic plasma emission in collisional plasma, and presented simulation results from this in homogeneous plasma and plasma with weak density fluctuations. We find that the effects of density inhomogeneities on Langmuir wave backscattering can be very significant even for low levels of plasma inhomogeneity. This has important effects
not only on the Langmuir wave evolution itself, but more signifi-
cantly can suppress the production of plasma radio emission. For
random density fluctuations with parameters as observed in the
solar corona, Langmuir wavenumber diffusion can completely
suppress plasma radio emission even in the presence of strong
Langmuir wave turbulence. Moreover, these density fluctuations
can simultaneously lead to electron self-acceleration, increasing
the number of fast electrons yet decreasing or completely hiding
the often-expected radio signature of Langmuir waves.
