Abstract We introduce the notion of T-stability for torsion-free Higgs sheaves as a natural generalization of the notion of T-stability for torsion-free coherent sheaves over compact complex manifolds. We prove similar properties to the classical ones for Higgs sheaves. In particular, we show that only saturated flags of torsion-free Higgs sheaves are important in the definition of T-stability. Using this, we show that this notion is preserved under dualization and tensor product with an arbitrary Higgs line bundle. Then, we prove that for a torsion-free Higgs sheaf over a compact Kähler manifold, ω-stability implies T-stability. As a consequence of this, we obtain the T-semistability of any reflexive Higgs sheaf with an admissible Hermitian–Yang–Mills metric. Finally, we prove that T-stability implies ω-stability if, as in the classical case, some additional requirements on the base manifold are assumed. In that case, we obtain the existence of admissible Hermitian–Yang–Mills metrics on any T-stable reflexive sheaf.

1 Introduction

The notion of T-stability was introduced by Bogomolov [3] in the case of coherent sheaves over projective algebraic manifolds, and it was studied latter by Kobayashi in [9,10] for coherent sheaves over compact complex manifolds. In the Kähler case, the T-stability was related to Mumford–Takemoto stability (also called ω-stability, where ω denotes the Kähler form of the base manifold). To be precise, it was shown by Bogomolov and Kobayashi that a
\(\omega\)-stable (resp. \(\omega\)-semistable) torsion-free coherent sheaf over a compact Kähler manifold \(X\) was \(T\)-stable (resp. \(T\)-semistable). They proved also the converse result if \(H^{1,1}(X, \mathbb{C})\) was one dimensional, or if \(\omega\) represented an integral class (so that \(X\) was projective algebraic) and \(\text{Pic}(X)/\text{Pic}^0(X) = \mathbb{Z}\), where here \(\text{Pic}^0(X)\) denotes the subgroup of the Picard group \(\text{Pic}(X)\) consisting of holomorphic line bundles with vanishing first Chern class. In proving the connection between these two concepts of stability, it was important to consider a classical vanishing theorem for holomorphic line bundles. As we will see, the same result is important also to connect these two notions of stability for Higgs sheaves.

Now, vanishing theorems are important in Complex Geometry. Indeed, some of these results, first proved by Bochner and Yano [14], have been used by Kobayashi [10] to prove one direction of the classical Hitchin–Kobayashi correspondence for holomorphic vector bundles over compact Kähler manifolds. As it is well known, this correspondence establishes an equivalence between the notion of \(\omega\)-polystability and the existence of Hermitian–Einstein metrics for such bundles. Kobayashi also proved that a holomorphic vector bundle admitting an approximate Hermitian–Einstein metric was \(\omega\)-semistable. As a consequence of this, it was followed that a holomorphic vector bundle over a compact Kähler manifold admitting a Hermitian–Einstein metric (resp. an approximate Hermitian–Einstein metric) was necessarily \(T\)-stable (resp. \(T\)-semistable). The Hitchin–Kobayashi correspondence has been extended to reflexive sheaves by Bando and Siu [1] by introducing the notion of admissible metric on a sheaf.

On the other hand, Higgs bundles and Higgs sheaves were introduced by Hitchin [8] and Simpson [12, 13] and they also introduced the corresponding notion of Mumford–Takemoto stability for these objects. As it is well known, several results on holomorphic vector bundles and coherent sheaves can be extended to Higgs bundles and Higgs sheaves. In particular, Vanishing theorems for Higgs bundles have been recently studied in [7], and Simpson proved in [12] a Hitchin–Kobayashi correspondence for Higgs bundles over compact Kähler manifolds, i.e., an equivalence between the notion of Mumford–Takemoto polystability and the existence of Hermitian–Yang–Mills metrics (henceforth usually abbreviated HYM-metric).

Now, Bruzzo and Graña Otero [4] proved that if a Higgs bundle admits an approximate Hermitian–Yang–Mills (henceforth abbreviated apHYM-metric), it is necessarily semistable in the sense of Mumford–Takemoto. Following the ideas of Bando and Siu [1], Biswas and Schumacher proved in [2] that a reflexive Higgs sheaf over a compact Kähler manifold is \(\omega\)-polystable if and only if it has an admissible Hermitian–Yang–Mills metric, which is indeed a Hitchin–Kobayashi correspondence for Higgs sheaves.

This article is organized as follows. In the second section, we review some basic definitions concerning Higgs sheaves and using a classical isomorphism involving determinants, we show that the determinant bundle of certain quotient Higgs sheaves is indeed a Higgs line bundle. In the final part of the second section, we review some results on reflexive Higgs sheaves and Higgs bundles and we rewrite a classical vanishing theorem of holomorphic line bundles over compact Kähler manifolds in the context of Higgs line bundles. In the third section, we introduce the notion of a weighted flag for a torsion-free Higgs sheaf, and using this we define the \(T\)-stability for torsion-free Higgs sheaves, as a natural extension of the notion of \(T\)-stability for torsion-free coherent sheaves introduced in [10]. Then, we prove some basic properties that are indeed extensions of classical results; in particular, we prove that in the definition of \(T\)-stability it is enough to consider saturated flags (i.e., flags in which the quotients between the Higgs sheaf and all Higgs subsheaves of the flag are torsion-free). We prove also that \(T\)-stability is preserved under tensor products with Higgs line bundles and dualizations. Finally, in the four section, we prove that in the Kähler case, a Mumford–Takemoto stable (resp. semistable) torsion-free Higgs sheaf is also \(T\)-stable (resp.
T-semistable and hence, as a consequence of the main result of Biswas and Schumacher in [2], we obtain that any reflexive Higgs sheaf with an admissible HYM-metric is necessarily T-semistable and it is in general a direct sum of T-stable Hermitian–Yang–Mills Higgs sheaves with equal slope; and that any locally free Higgs sheaf admitting a HYM-metric (resp. apHYM-metric) is T-stable (resp. T-semistable). At the end, we show that if either \( H^{1,1}(X, \mathbb{C}) \) is one dimensional or if \( \omega \) represents an integral class and \( \text{Pic}(X)/\text{Pic}^0(X) = \mathbb{Z} \), the classical proof of Kobayashi for the converse implication (i.e., T-stability as a sufficient condition of \( \omega \)-stability) can be easily adapted to the Higgs case.

2 Preliminaries

We start with some basic definitions. Let \( X \) be a compact complex manifold of complex dimension \( n \) and let \( \Omega^1_X \) be the cotangent sheaf to \( X \). A Higgs sheaf over \( X \) is a pair \( \mathcal{E} = (E, \phi) \) where \( E \) is a coherent sheaf over \( X \) and \( \phi : E \rightarrow E \otimes \Omega^1_X \) is a morphism of \( \mathcal{O}_X \)-modules such that \( \phi \wedge \phi : E \rightarrow E \otimes \Omega^2_X \) vanishes. The morphism \( \phi \) is usually called the Higgs field. A section \( s \) of \( E \) is said to be a \( \phi \)-invariant section of \( \mathcal{E} \), if there exists a holomorphic 1-form \( \lambda \) of \( X \) such that \( \phi(s) = s \otimes \lambda \). A Higgs sheaf \( \mathcal{E} \) is said to be torsion-free (resp. locally free, reflexive, normal, torsion) if the coherent sheaf \( E \) is torsion-free (resp. locally free, reflexive, normal, torsion). The support of a Higgs sheaf is the support of the corresponding coherent sheaves with equal slope; and that any locally free Higgs sheaf with an admissible HYM-metric is necessarily \( T \)-semistable and it is in general a direct sum of \( T \)-stable Higgs sheaves with equal slope; and that any locally free Higgs sheaf admitting a HYM-metric (resp. apHYM-metric) is \( T \)-stable (resp. \( T \)-semistable) if the coherent sheaf \( E \) has codimension at least two, \( \det \mathcal{E} \) represents an integral class and \( \text{Pic}(X)/\text{Pic}^0(X) = \mathbb{Z} \), we know that \( \det T \) admits a nonzero holomorphic section and, in particular, if \( \text{supp}(\Sigma) \) has codimension at least two, \( \det \Sigma \) is a trivial holomorphic line bundle.

As it is well known [2], on Higgs sheaves we can apply the same operations that we normally apply to sheaves. For instance, the dual of a Higgs sheaf and its pullback are again Higgs sheaves, and tensor products and the direct sums of Higgs sheaves are Higgs sheaves. If \( \mathcal{E} \) is a Higgs sheaf we denote its dual by \( \mathcal{E}^* \), and if \( \mathcal{E} \rightarrow Y \rightarrow X \) is a map between compact complex manifolds, we denote its pullback by \( \mathcal{E} \). If now \( \mathcal{E}_1 \) and \( \mathcal{E}_2 \) are Higgs sheaves, we denote its tensor product and direct sum by \( \mathcal{E}_1 \otimes \mathcal{E}_2 \) and \( \mathcal{E}_1 \oplus \mathcal{E}_2 \), respectively. Now, a Higgs subsheaf \( \mathcal{F} \) of \( \mathcal{E} \) is a subsheaf \( F \) of \( E \) such that \( \phi(F) \subset F \otimes \Omega^1_X \), and hence the pair \( \mathcal{F} = (F, \phi|_F) \) becomes itself a Higgs sheaf. A morphism \( f : \mathcal{E}_1 \rightarrow \mathcal{E}_2 \) between two Higgs sheaves over \( X \) is a morphism \( f : E_1 \rightarrow E_2 \) of the corresponding coherent sheaves such that the diagram

\[
\begin{array}{c}
E_1 \xrightarrow{\phi_1} E_1 \otimes \Omega^1_X \\
\downarrow f \downarrow f \otimes 1 \\
E_2 \xrightarrow{\phi_2} E_2 \otimes \Omega^1_X
\end{array}
\]

is commutative. If \( \mathcal{E} = (E, \phi) \) is a Higgs sheaf over \( X \), the natural morphism \( \sigma : E \rightarrow E^{**} \) is a first example of a Higgs morphism \( \sigma : \mathcal{E} \rightarrow \mathcal{E}^{**} \). The kernel and the image of Higgs morphisms are Higgs sheaves and the torsion subsheaf of a Higgs sheaf is again a Higgs sheaf (see [6] for details), these two results will be particularly important in the study of \( T \)-stability. An exact sequence of Higgs sheaves is an exact sequence of the corresponding coherent sheaves in which each morphism is a morphism of Higgs sheaves.

Let \( \mathcal{E} \) be a torsion-free Higgs sheaf of rank \( r \), from a classical result (see [10] for details of this and what follows) we know that \( \det E \cong \left( \bigwedge^r E \right)^{**} \) and hence, using this isomorphism,
it is possible to induce a Higgs field on the determinant bundle. As a consequence of this, we see that the determinant bundle of a torsion-free Higgs sheaf is a Higgs line bundle, we denote this bundle by det $\mathcal{E}$. Clearly, from this definition, we have canonically det $\mathcal{E} \cong (\bigwedge^r \mathcal{E})^{**}$ as an isomorphism of Higgs bundles. Now, let us consider the short exact sequence of Higgs sheaves

$0 \to \mathfrak{g} \to \mathcal{E} \to \mathcal{G} \to 0$

(also called a Higgs extension). If $\mathcal{E}$ is torsion-free, then $\mathfrak{g}$ is torsion-free, but $\mathcal{G}$ may have torsion. In this case, we induce a Higgs morphism on det $G$ using the Higgs fields of det $\mathfrak{g}$ and det $\mathcal{E}$, and the isomorphism det $G \cong (\det F)^{-1} \otimes \det E$. We denote by det $\mathcal{G}$ the Higgs line bundle defined by det $G$ and this induced morphism. In this way, we obtain det $\mathcal{E} \cong \text{det} \mathfrak{g} \otimes \text{det} \mathcal{G}$ as an isomorphism of Higgs bundles.

Suppose now that $X$ is a Kähler manifold with $\omega$ its Kähler form, then the first Chern class of $\mathcal{E}$ is by definition the first Chern class of $E$, and hence following Kobayashi [10], $c_1(\mathcal{E}) = c_1(\det E)$ and the degree of $\mathcal{E}$ is given by

$$\deg \mathcal{E} = \int_X c_1(\mathcal{E}) \wedge \omega^{n-1}. \quad (1)$$

It is important to note that the degree defined by (1) depends on $\omega$ if the complex dimension of $X$ is greater than one. Now, if we denote the rank of $\mathcal{E}$ by rk $\mathcal{E}$, and if this rank is positive, we introduce the quotient $\mu(\mathcal{E}) = \deg \mathcal{E} / \text{rk} \mathcal{E}$, which is called the slope of the Higgs sheaf. A Higgs sheaf $\mathcal{E}$ is said to be $\omega$-stable (resp. $\omega$-semistable), if it is torsion-free and for any Higgs subsheaf $\mathfrak{g}$ with $0 < \text{rk} \mathfrak{g} < \text{rk} \mathcal{E}$ we have the inequality $\mu(\mathfrak{g}) < \mu(\mathcal{E})$ (resp. $\leq$). We say that a Higgs sheaf is $\omega$-polystable if it decomposes into a direct sum of two or more $\omega$-stable Higgs sheaves, all these with the same slope.

This notion of stability was introduced by Hitchin [8] and Simpson [12] as an analog of the Mumford–Takemoto stability for coherent sheaves [10]. However, it is important to note that the coherent sheaf $E$ associated to a torsion-free Higgs sheaf $\mathcal{E}$ is $\omega$-stable (resp. $\omega$-semistable) if and only if for any proper nontrivial subsheaf $F$ of $E$, we have $\mu(F) < \mu(E)$ (resp. $\leq$). Therefore, if $\mathcal{E}$ is $\omega$-stable (resp. $\omega$-semistable) in the classical sense, it is $\omega$-stable (resp. $\omega$-semistable) as a Higgs object, but the converse is not true in general (see [8] for examples). In this sense, the notion of $\omega$-stability for Higgs sheaves is a generalization of the classical notion of $\omega$-stability for coherent sheaves.

As it is well known (see for instance [6] or [12]), for this notion of stability it is suffice to consider only Higgs subsheaves with torsion-free quotients (we will see in the next section that there exists a similar result for $T$-stability). As we said before, Biswas and Schumacher proved [2] the equivalence between $\omega$-stability and the existence of HYM-metrics for Higgs sheaves. To be precise, they proved the following result:

**Theorem 2.1** Let $\mathcal{E}$ be a reflexive Higgs sheaf over a compact Kähler manifold $X$ with Kähler form $\omega$. Then, there exists an admissible HYM-metric on $\mathcal{E}$ if and only if it is $\omega$-polystable.

A Higgs bundle is by definition a locally free Higgs sheaf. We say that a Higgs bundle is Hermitian flat if there exists a Hermitian metric $h$ on it, such that the Hitchin–Simpson connection $\mathcal{D}_h = D_h + \phi + \bar{\phi}_h$ is flat, i.e., if the Hitchin–Simpson curvature $\mathcal{R}_h = \mathcal{D}_h \wedge \mathcal{D}_h$ vanishes. Now, following [4] we know that

$$\mathcal{R}_h = R_h + D'_h(\phi) + D''(\bar{\phi}_h) + [\phi, \bar{\phi}_h] \quad (2)$$

where $R_h$ is the Chern curvature, $D'_h$ and $D''$ are the holomorphic and anti-holomorphic parts of the Chern connection $D_h$ and the commutator is the usual abbreviation for $\phi \wedge \bar{\phi}_h + \bar{\phi}_h \wedge \phi$. 
Now, on the right hand side of (2), the third term is the adjoint of the second term and since for Higgs line bundles the commutator is zero, a Higgs line bundle \( L = (L, \phi) \) is Hermitian flat if and only if \( R_h = 0 \) (i.e., \( L \) is Hermitian flat in the classical sense) and the Higgs field satisfies \( D'_h \phi = 0 \). Notice that in the case of Higgs line bundles, any Higgs morphism is in essence a holomorphic 1-form, hence every holomorphic section of a Higgs line bundle is an invariant section.

On the other hand, in Complex Geometry, there is a well-known vanishing theorem for holomorphic line bundles depending on its degree [10], since the degree of a Higgs bundle is the same degree of the corresponding vector bundle, this result can be applied to Higgs line bundles, and hence the classical vanishing theorem in the Higgs context becomes

**Proposition 2.2** Let \( L \) be a Higgs line bundle over a compact Kähler manifold \( X \). Then,

(i) If \( \deg L < 0 \), then \( L \) admits no nonzero (invariant) holomorphic sections;

(ii) If \( \deg L = 0 \), then every nonzero (invariant) holomorphic section of \( L \) has no zeros.

Finally, as it is well known, in the case of Higgs bundles over compact Kähler manifolds, Simpson [12] proved a Hitchin–Kobayashi correspondence, and Bruzzo and Graña Otero proved in [4] that Higgs bundles admitting apHYM-metrics are semistable in the sense of Mumford–Takemoto. The converse of this result has been proved in [5] in the one-dimensional case and by Li and Zhang [11] for compact Kähler manifolds of greater dimensions. These results can be summarized as follows:

**Theorem 2.3** Let \( E \) be a Higgs bundle over a compact Kähler manifold \( X \) with Kähler form \( \omega \). Then, there exists a HYM-metric (resp. apHYM-metric) on \( E \) if and only if it is \( \omega \)-polystable (resp. \( \omega \)-semistable).

Notice that, since for compact Kähler manifolds an admissible HYM-metric is just a HYM-metric, part of Theorem 2.3 is indeed a particular case of Theorem 2.1. However, there is known a differential geometric analog of \( \omega \)-semistability only for bundles\(^1\) and it is precisely the notion of apHYM-metric, a natural extension for Higgs bundles of an approximate Hermitian–Einstein structure for holomorphic vector bundles.

### 3 \( T \)-stability

To define the notion of \( T \)-stability, we need to define first the notion of a weighted flag in the Higgs case. Let \( E \) be a torsion-free Higgs sheaf over a compact complex manifold \( X \), a weighted flag of \( E \) is a sequence of pairs \( \mathcal{F} = \{ (E_i, n_i) \}_{i=1}^k \) consisting of Higgs subsheaves

\[
E_1 \subset E_2 \subset \cdots \subset E_k \subset E
\]

together with positive integers \( n_1, n_2, \ldots, n_k \) and such that

\[
0 < \text{rk } E_1 < \text{rk } E_2 < \cdots < \text{rk } E_k < \text{rk } E.
\]

Let \( r_i = \text{rk } E_i \) and \( r = \text{rk } E \). In analogy to the classical case, to each weighted flag \( \mathcal{F} \) we associate the Higgs line bundle

\[
\mathcal{L}_\mathcal{F} = \prod_{i=1}^k ((\text{det } E_i)^{r_i} \otimes \left( \text{det } E \right)^{-r_i})^{n_i}.
\]

\(^1\) Indeed, even in the classical case of reflexive sheaves, there is no yet an equivalence of \( \omega \)-semistability (see [1] for more details).
We say that a weighted flag $F$ is saturated if the quotients $E/E_i$, $i = 1, 2, \ldots, k$, are all torsion-free. A torsion-free Higgs sheaf $E$ over $X$ is said to be $T$-stable (resp. $T$-semistable), if for every weighted flag $F$ of $E$ and every Hermitian flat Higgs line bundle $\mathcal{L}$ over $X$, the Higgs line bundle $\mathcal{I}_F \otimes \mathcal{L}$ admits no nonzero holomorphic sections (resp. every nonzero holomorphic section of $\mathcal{I}_F \otimes \mathcal{L}$, if any, vanishes nowhere on $X$). Notice that since weighted flags for Higgs sheaves consist of Higgs subsheaves, if a Higgs sheaf is $T$-stable (resp. $T$-semistable) in the classical sense, it is also $T$-stable (resp. $T$-semistable) in the Higgs sense. However, as we will see in the next section, the converse is not true in general.

From this definition of $T$-stability, we have the following results, which are natural extensions to the Higgs case of classical results of Kobayashi [10].

**Proposition 3.1** Let $E$ be a torsion-free Higgs sheaf over a compact complex manifold $X$. Then, it is $T$-stable (resp. $T$-semistable) if and only if for every saturated flag $F$ of $E$ and every Hermitian flat Higgs line bundle $\mathcal{L}$ over $X$, the bundle $\mathcal{I}_F \otimes \mathcal{L}$ admits no nonzero holomorphic sections (resp. every holomorphic section of $\mathcal{I}_F \otimes \mathcal{L}$, if any, vanishes nowhere on $X$).

*Proof* There is nothing to prove in one direction. Now, to prove the other direction, let us assume that such conditions on existence or not of holomorphic sections are satisfied for any saturated flag and any Hermitian flat Higgs line bundle.

Let $F' = \{(E_i, n_i)\}_{i=1}^k$ be an arbitrary flag of $E$ and $\mathcal{L}$ a Hermitian flat Higgs line bundle. Let $\mathcal{I}_i$ be the torsion of $E/E_i$. Then, if we define $\tilde{E}_i$ as the kernel of the morphism $E \to (E/E_i)/\mathcal{I}_i$ we obtain the following commutative diagram

\[
\begin{array}{ccccccccc}
0 & \to & 0 & \to & \mathcal{I}_i & \to & 0 \\
& & \downarrow & & \downarrow & & \\
& & 0 & \to & E & \to & \mathcal{E} & \to & \mathcal{E}/E_i & \to & 0 \\
& & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
& & 0 & \to & \tilde{E}_i & \to & \mathcal{E} & \to & \tilde{E}/\tilde{E}_i & \to & 0 \\
& & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
& & \tilde{E}_i/E_i & \to & \mathcal{I}_i & \to & 0 & & 0 & \to & 0 \\
\end{array}
\]

with $\mathcal{I}_i \cong \tilde{E}_i/E_i$. Since $\tilde{E}_i$ and $E_i$ are torsion-free, from Sect. 2 we see that the determinant of $\tilde{E}_i/E_i$ is a Higgs bundle, and consequently also is the determinant of $\mathcal{I}_i$ and we have

\[1\] If $E$ is $T$-stable (resp. $T$-semistable), the conditions on existence or not of holomorphic sections hold for any flag and any Hermitian flat Higgs line bundle; in particular, this is true if the flag is saturated.
\[ \det \tilde{E}_i \cong \det E_i \otimes \det \mathcal{T}_i. \] If we use this isomorphism and we consider now the saturated flag\(^3\)
\[ \tilde{F} = \{(\tilde{E}_i, n_i)\}_{i=1}^k \] of \(E\), we get
\[ \mathcal{F}_\tilde{F} = \prod_{i=0}^k ((\det \tilde{E}_i)^r \otimes (\det E)^{-r})^{n_i} \cong \mathcal{F}_F \otimes \prod_{i=1}^k (\det \mathcal{T}_i)^{r n_i}. \]

Since each \(\mathcal{T}_i\) is torsion, from a classical result in [10], each \(\det \mathcal{T}_i\) admits a nonzero holomorphic section. Now, since \(\tilde{F}\) is saturated, these conditions on the existence or not of holomorphic sections are satisfied for \(\mathcal{F}_\tilde{F} \otimes \mathcal{L}\). At this point, using the isomorphism above if follows that the same is true also for the Higgs line bundle \(\mathcal{F}_F' \otimes \mathcal{L}\).

**Proposition 3.2** Let \(E\) be a torsion-free Higgs sheaf over a compact complex manifold \(X\). Then,

(i) If \(\text{rk} \ E = 1\), then \(E\) is \(T\)-stable;

(ii) If \(\mathcal{L}\) is a Higgs line bundle over \(X\), then the tensor product \(E \otimes \mathcal{L}\) is \(T\)-stable (resp. \(T\)-semistable) if and only if \(E\) is \(T\)-stable (resp. \(T\)-semistable);

(iii) \(E\) is \(T\)-stable (resp. \(T\)-semistable) if and only if its dual \(E^*\) is \(T\)-stable (resp. \(T\)-semistable).

**Proof** If \(\text{rk} \ E = 1\), there are no flags to be considered, hence (i) is trivial. Suppose now that \(\mathcal{L}\) is a Higgs line bundle, then in analogy to the classical case, there exists a natural correspondence between flags \(F = \{(E_i, n_i)\}\) of \(E\) and flags \(F' \cong \{(E_i \otimes \mathcal{L}, n_i)\}\) of \(E \otimes \mathcal{L}\). Now, since \(E\) and \(E_i\) are torsion-free and we have the identities
\[ \bigwedge^r (E_i \otimes \mathcal{L}) \cong \bigwedge^r E_i \otimes \mathcal{L}^{n_i}, \quad \bigwedge^r (E \otimes \mathcal{L}) \cong \bigwedge^r E \otimes \mathcal{L}^{r'}, \]
we have the following isomorphisms of determinant Higgs bundles
\[ \det(E_i \otimes \mathcal{L}) \cong \det E_i \otimes \mathcal{L}^{n_i}, \quad \det(E \otimes \mathcal{L}) \cong \det E \otimes \mathcal{L}^{r'}. \]

Now, using these isomorphisms and the expression (3) for the flag \(F \otimes \mathcal{L}\), we obtain
\[ \mathcal{F}_{F \otimes \mathcal{L}} = \prod_{i=1}^k ((\det(E_i \otimes \mathcal{L})^r \otimes (\det E \otimes \mathcal{L})^{-r})^{n_i} \cong \prod_{i=1}^k ((\det E_i^r \otimes \mathcal{L}^{n_i}) \otimes (\det E)^{-r} \otimes \mathcal{L}^{-r})^{n_i} \cong \mathcal{F}_F \]
and (ii) follows. Finally, assume that \(E^*\) is \(T\)-stable (resp. \(T\)-semistable) and let \(F = \{(E_i, n_i)\}_{i=1}^k\) be a saturated flag of \(E\). By dualizing the Higgs extension of \(E\) associated to \(E_i\) we get the exact sequence
\[ 0 \rightarrow (E/E_i)^* \rightarrow E^* \rightarrow E^*_i \]
\[ \text{Since } E_i \subset E_{i+1}, \text{ there exists a map } E/E_i \rightarrow E/E_{i+1} \text{ such that the obvious diagram commutes. Now, any element in } E_i \text{ can be projected on } E_i/E_i \cong \mathcal{T}_i \subset \mathcal{T}_{i+1}, \text{ so it is zero in } E/E_{i+1} \text{ and hence } E_i \subset E_{i+1} \text{ and } \tilde{F} \text{ is a flag, which is obviously saturated.} \]

\(\Box\) Springer
with \( \text{rk}(\mathcal{E}/\mathcal{E}_i)^* = r - r_i \) and we obtain from this a flag \( \mathcal{F}^* = \{(\mathcal{E}/\mathcal{E}_i)^*, n_i)\} \) of \( \mathcal{E}^* \) with
\[
(\mathcal{E}/\mathcal{E}_k)^* \subset \cdots \subset (\mathcal{E}/\mathcal{E}_1)^* \subset \mathcal{E}^*.
\]

Now, \( \mathcal{E} \) is torsion-free and \( \mathcal{E}/\mathcal{E}_i \) is torsion-free because the flag \( \mathcal{F} \) is saturated, then \( \det \mathcal{E}^* \cong (\det \mathcal{E})^* \) and \( \det(\mathcal{E}/\mathcal{E}_i)^* \cong (\det \mathcal{E}/\mathcal{E}_i)^* \) and hence
\[
\mathcal{I}_{\mathcal{F}^*} = \prod_{i=1}^k \left( (\det(\mathcal{E}/\mathcal{E}_i)^*)^r \otimes (\det \mathcal{E}^*)^{-(r-r_i)} \right)^{n_i}
\]
\[
\cong \prod_{i=1}^k \left( (\det \mathcal{E}/\mathcal{E}_i)^r \otimes (\det \mathcal{E})^{r-r_i} \right)^{n_i}
\]
\[
\cong \prod_{i=1}^k \left( (\det \mathcal{E}_i)^r \otimes (\det \mathcal{E})^{-r_i} \right)^{n_i} = \mathcal{I}_{\mathcal{F}}
\]
and it follows that \( \mathcal{E} \) is \( T \)-stable (resp. \( T \)-semistable). Conversely, assume that \( \mathcal{E} \) is \( T \)-stable (resp. \( T \)-semistable) and let \( \mathcal{F}^* = \{\mathcal{H}_i, n_i\}_{i=1}^k \) be a saturated flag of \( \mathcal{E}^* \). Then, for \( \mathcal{H}_i \), we have the short exact sequence
\[
0 \longrightarrow \mathcal{H}_i \longrightarrow \mathcal{E}^* \longrightarrow \mathcal{H}_i^* \longrightarrow 0 \tag{4}
\]
with \( \mathcal{H}_i = \mathcal{E}^*/\mathcal{H}_i \) torsion-free. By dualizing the Higgs extension (4), we get the exact sequence
\[
0 \longrightarrow \mathcal{H}_i^* \longrightarrow \mathcal{E}^{**} \longrightarrow \mathcal{H}_i^* \longrightarrow 0.
\]

Since \( \mathcal{E} \) is torsion-free, the natural morphism \( \sigma : \mathcal{E} \rightarrow \mathcal{E}^{**} \) is injective and we can consider the Higgs sheaf \( \mathcal{E}_i = \sigma(\mathcal{E}) \cap \mathcal{H}_i^* \) as a Higgs subsheaf of \( \mathcal{E} \) with rank \( r_i = r - \text{rk} \mathcal{H}_i \). From this, we have a flag \( \mathcal{F} = \{(\mathcal{E}_i, n_i)\} \) of \( \mathcal{E} \) with
\[
\mathcal{E}_k \subset \mathcal{E}_{k-1} \subset \cdots \subset \mathcal{E}_1 \subset \mathcal{E}.
\]

Now, we define torsion Higgs sheaves \( \mathcal{I} = \mathcal{E}^{**}/\mathcal{E} \) and \( \mathcal{I}_i = \mathcal{H}_i^*/\mathcal{E}_i \subset \mathcal{I} \). Again, since \( \mathcal{E} \) is torsion-free, \( \det \mathcal{E}^{**} \cong \det \mathcal{E} \) and consequently \( \det \mathcal{I} \) is trivial (as a classical bundle) and \( \det \mathcal{I}_i \cong \det \mathcal{E}_i \). From this, we get
\[
\det \mathcal{H}_i \cong \det \mathcal{E}^* \otimes (\det \mathcal{H}_i)^{-1} \cong \det \mathcal{E}^* \otimes \det \mathcal{H}_i \cong \det \mathcal{E}^* \otimes \det \mathcal{E}_i. \tag{5}
\]

Then, from (5), we get
\[
\mathcal{I}_{\mathcal{F}^*} = \prod_{i=1}^k \left( (\det \mathcal{H}_i)^r \otimes (\det \mathcal{E}^*)^{r-r_i} \right)^{n_i}
\]
\[
\cong \prod_{i=1}^k \left( (\det \mathcal{E}_i)^r \otimes (\det \mathcal{E})^{r-r_i} \right)^{n_i}
\]
\[
\cong \prod_{i=1}^k \left( (\det \mathcal{E}_i)^r \otimes (\det \mathcal{E})^{-r_i} \right)^{n_i} = \mathcal{I}_{\mathcal{F}}
\]
From this isomorphism, it follows that \( \mathcal{E}^* \) is \( T \)-stable (resp. \( T \)-semistable) and hence we have proved (iii). \( \square \)
4 The Kähler case

As it is well known [10], if $X$ is Kähler there exists a connection between the Mumford–Takemoto stability and $T$-stability for coherent sheaves. This result extends naturally to Higgs sheaves and can be written as:

**Theorem 4.1** Let $\mathcal{E}$ be a torsion-free Higgs sheaf over a compact Kähler manifold $X$ with Kähler form $\omega$. If $\mathcal{E}$ is $\omega$-stable (resp. $\omega$-semistable), then it is $T$-stable (resp. $T$-semistable).

**Proof** Assume that $\mathcal{E}$ is $\omega$-stable (resp. $\omega$-semistable) and let $F = \{(\mathcal{E}_i, n_i)\}_{i=1}^k$ be a flag (not necessarily saturated) of $\mathcal{E}$. Then, as in the classical case, we have

$$
\int_X c_1(\mathcal{F}) \wedge \omega^{n-1} = \sum_{i=1}^k n_i \int_X c_1[(\det \mathcal{E}_i)^r \otimes (\det \mathcal{E})^{-r_i}] \wedge \omega^{n-1}
$$

$$
= \sum_{i=1}^k n_i \int_X (r c_1(\mathcal{E}_i) - r_i c_1(\mathcal{E})) \wedge \omega^{n-1}
$$

$$
= \sum_{i=1}^k n_i r_i (\mu(\mathcal{E}_i) - \mu(\mathcal{E})) < 0 \quad \text{(resp.} \leq 0)\text{). If } \mathcal{L} \text{ is a Hermitian flat Higgs line bundle, in particular } c_1(\mathcal{L}) = 0 \text{ and we have}
$$

$$
\deg(\mathcal{F} \otimes \mathcal{L}) = \int_X c_1(\mathcal{F} \otimes \mathcal{L}) \wedge \omega^{n-1} = \int_X c_1(\mathcal{F}) \wedge \omega^{n-1} < 0 \quad \text{(resp.} \leq 0)\text{. Therefore, using Proposition 2.2 it follows that } \mathcal{E} \text{ is } T\text{-stable (resp. } T\text{-semistable).}
$$

At this point, as a direct consequence of Theorems 4.1 and 2.1, we obtain the following result for reflexive Higgs sheaves over compact Kähler manifolds.

**Corollary 4.2** Let $\mathcal{E}$ be a reflexive Higgs sheaf over a compact Kähler manifold $X$. If $\mathcal{E}$ has an admissible HYM-metric, then it is $T$-semistable and $\mathcal{E} = \bigoplus_{i=1}^s \mathcal{E}_i$, where each $\mathcal{E}_i$ is a $T$-stable Hermitian–Yang–Mills Higgs sheaf with $\mu(\mathcal{E}_i) = \mu(\mathcal{E})$.

If, on the other hand, we consider locally free Higgs sheaves over compact Kähler manifolds, then there exists a relation between the notion of HYM-metric and the concept of $T$-stability. In fact, from Theorems 4.1 and 2.3, we obtain

**Corollary 4.3** Let $\mathcal{E}$ be a Higgs bundle over a compact Kähler manifold $X$. Then,

(i) If $\mathcal{E}$ admits a HYM-metric, then it is $T$-semistable and $\mathcal{E} = \bigoplus_{i=1}^s \mathcal{E}_i$, where each $\mathcal{E}_i$ is a $T$-stable Hermitian–Yang–Mills Higgs bundle with $\mu(\mathcal{E}_i) = \mu(\mathcal{E})$;

(ii) If $\mathcal{E}$ admits an apHYM-metric, then it is $T$-semistable.

Notice that, the part (i) of Corollary 4.3 can be seen as a particular case of Corollary 4.2, however the part (ii) is new. Now, Kobayashi proved in [10] a partial converse of this Corollary for torsion-free sheaves. The proof of Kobayashi can be easily adapted to Higgs sheaves and gives a partial converse of Theorem 4.1. So we have the following

**Theorem 4.4** Let $\mathcal{E}$ be a torsion-free Higgs sheaf over a compact Kähler manifold $X$ with Kähler form $\omega$ and assume either
The dimension of $H^{1,1}(X, \mathbb{C})$ is equal to one; or

(b) $\omega$ represents an integral class and $\operatorname{Pic}(X)/\operatorname{Pic}^0(X) = \mathbb{Z}$.

If $\mathcal{E}$ is $T$-stable (resp. $T$-semistable), then it is $\omega$-stable (resp. $\omega$-semistable).

Proof In analogy to the classical proof of Kobayashi, let $\mathcal{E}'$ be any Higgs subsheaf of $\mathcal{E}$ with nonzero rank $r' < r$, and consider the Higgs line bundle

$$\mathcal{U} = (\det \mathcal{E}')^r \otimes (\det \mathcal{E})^{-r'}$$

with its degree given by

$$\deg \mathcal{U} = \int_X (r c_1(\mathcal{E}') - r' c_1(\mathcal{E})) \wedge \omega^{n-1} = rr'(\mu(\mathcal{E}') - \mu(\mathcal{E})).$$

If $[\omega]$ denotes the cohomology class of $\omega$, from either of hypothesis (a) or (b), we obtain $c_1(\mathcal{U}) = a[\omega]$ for some $a \in \mathbb{R}$; hence, by integrating this formula, it follows that $\deg \mathcal{U} = 0$ (resp. $> 0$) if and only if $a = 0$ (resp. $> 0$).

If $\mathcal{E}$ is not $\omega$-semistable, there exists a Higgs subsheaf $\mathcal{E}'$ such that $\mu(\mathcal{E}') > \mu(\mathcal{E})$. Then, for the corresponding Higgs line bundle $\mathcal{U}$ defined by (6), we get $\deg \mathcal{U} > 0$ and hence $a > 0$. From this we know that there exists a positive integer $p$ such that $\mathcal{U}^p$ admits a nonzero section, say $s$. Now, if $s$ vanishes nowhere on $X$, then $\mathcal{U}^p$ is trivial as a classical bundle and $c_1(\mathcal{U}^p) = 0$ and therefore $a = 0$, which is a contradiction. Therefore, $s$ necessarily vanishes at some point. In particular, $\mathcal{U}^p \otimes \mathcal{L}$ admits a nonzero section, vanishing at some point, for any Hermitian flat Higgs line bundle $\mathcal{L}$ with $L$ trivial. This shows that $\mathcal{E}$ is not $T$-semistable if it is not $\omega$-semistable.

If $\mathcal{E}$ is not $\omega$-stable, then there exists a Higgs subsheaf $\mathcal{E}'$ such that $\mu(\mathcal{E}') \geq \mu(\mathcal{E})$. Now, if the inequality is strict it is also not $\omega$-semistable, and hence from the above analysis we conclude that it is not $T$-semistable and in particular it is not $T$-stable. If, on the other hand $\mu(\mathcal{E}') = \mu(\mathcal{E})$, it follows that $\deg \mathcal{U} = 0$ and $a = 0$. Hence, the corresponding $\mathcal{U}$ is flat as a classical bundle. Then, by defining $\mathcal{L} = (U^{-1}, 0)$, with $U$ the holomorphic line bundle associated to $\mathcal{U}$, it follows that $\mathcal{U} \otimes \mathcal{L}$ is trivial as a classical bundle and hence it admits a nonzero holomorphic section. This shows that $\mathcal{E}$ is not $T$-stable if it is not $\omega$-stable. \(\square\)

As it is well known [8], there are Higgs bundles over curves that are stable in the sense of Mumford–Takemoto, that are not stable as classical bundles. From Theorem 4.1, these bundles are $T$-stable as Higgs bundles. Now, from Kobayashi [10] it is known that for holomorphic bundles over curves, the notions of Mumford–Takemoto stability and $T$-stability are equivalent; hence, such Higgs bundles are not $T$-stable in the classical sense. This fact shows that $T$-stability is indeed an extension of the classical notion of $T$-stability. Finally, as a direct consequence of Theorems 4.4 and 2.1, we get a partial converse of Corollary 4.2. To be precise, we have the following result.

Corollary 4.5 Let $\mathcal{E}$ be a reflexive Higgs sheaf over a compact Kähler manifold $X$ and assume that either (a) or (b) of Theorem 4.4 holds. If $\mathcal{E}$ is $T$-stable, then it has an admissible HYM-metric.

This Corollary can be extended to $T$-semistable Higgs sheaves in a very special case. Indeed, if $\mathcal{E}$ is $T$-semistable and $\mathcal{E} = \bigoplus_{i=1}^s \mathcal{E}_i$, where each $\mathcal{E}_i$ is a $T$-stable Higgs sheaf with $\mu(\mathcal{E}_i) = \mu(\mathcal{E})$, then from Corollary 4.5 each $\mathcal{E}_i$ has an admissible HYM-metric and (see [2] or [6] for details) we get also an admissible HYM-metric on $\mathcal{E}$.

Notice that non $T$-semistability means that there exists a nonzero section of $T_\mathcal{F} \otimes \mathcal{L}$ for some flag $\mathcal{F}$ and some $\mathcal{L}$ Hermitian flat Higgs line bundle, and such a section vanishes at least at some point.
Acknowledgments  This paper was mostly done during a stay of the author at the International School for Advanced Studies (SISSA) in Trieste, Italy. The author wants to thank SISSA for the hospitality and support. Finally, the author would like to thank U. Bruzzo for some useful comments and suggestions.
