In vitro antioxidant, collagenase inhibition, and in vivo anti-wrinkle effects of combined formulation containing Punica granatum, Ginkgo biloba, Ficus carica, and Morus alba fruits extract

Background: In phytotherapy, the therapeutic potential is based on the combined action of different herbal drugs. Our objective was to evaluate the antioxidant, anti-collagenase (in vitro), and anti-wrinkle (in vivo) effect of combined formulation containing Ginkgo biloba, Punica granatum, Ficus carica, and Morus alba fruits extract.

Methods: Antioxidant evaluation was based on the scavenging activity of free radicals (1,1-diphenyl-2-picrylhydrazyl, \(\text{H}_2\text{O}_2\), and \(\text{O}^\cdot\)) and the anti-collagenase activity was based on the reduction of collagenase enzyme in vitro. In an in vivo study, 21 female subjects were examined in a placebo-controlled trial. Facial wrinkles, especially the crow’s feet region of eyes, was treated with topical formulated 2% cream for 56 days and compared with the placebo.

Results: In the in vitro study, the combination of fruits extract showed a higher antioxidant activity which was comparable with the positive standard (ascorbic acid, butylated hydroxyanisole, and Trolox). The data also showed a dose-dependent inhibition of collagenase. In the in vivo study, treatment with 2% formulated cream for 56 days significantly reduced the percentage of wrinkle depth, length, and area with 11.5, 10.07, and 29.55, respectively.

Conclusion: The combined formulation of fruit extracts showed excellent antioxidative and anti-collagenase activity as well as a significant effect on anti-wrinkle activity on human skin.

Keywords: antioxidant, anti-collagenase, anti-wrinkle, fruits, topical formulation

Introduction

Plant extracts rich in phytochemicals such as flavonoids, phenolic acids, tocopherols, alkaloids, and monoterpens, having antioxidant or anti-inflammatory activity, are being widely used for the development of topical cosmetic products. Recently in market, an increased number of pharmaceutical or cosmetic products with the combination of several herbal extracts have been introduced. It is found that the multiple combinations of plants extract have shown higher phytotherapy efficacy compared with the products with single extracts. For instance, clinical evidences of synergy effects of Valeriana officinalis + Humulus lupulus, V. officinalis + Kava-kava, Urtica dioica + Pygeum africanum, Ginseng + Ginkgo always showed higher efficacy than their single extract. Likewise, extracts of Hypericum perforatum, Sabal serrulata, Hedera helix, and Boswellia serrata also showed better therapeutic efficacy than that of the synthetic drugs (standard) used in the clinical studies. Other studies have shown the pharmaceutical superiority of the extracts over the isolated compounds. For example, Valeriana extract (V. officinalis), Zingiber extract (Zingiber officinalis), Ginkgo extract
(Ginkgo biloba), Piper methysticum, and Licorice extract (Glycyrrhiza glabra) showed higher efficacy than that of its individual constituents.4

The present investigation has been carried out on four different plants (Punica granatum, Ficus carica, Morus alba, and G. biloba) fruit extracts whose individual pharmaceutial efficacy has already been understood. For instance, P. granatum fruit (Punicaceae family) extract is widely used in therapeutics, cosmetics, and food seasonings. The fruit extract showed its protective and chemopreventive properties in human skin fibroblasts against ultraviolet- (UVA and UVB) induced damage.5 The extract also have efficacy to inhibit matrix metalloproteinase (MMP)-1 produced by dermal fibroblasts.6

Morus alba (Moraceae family) fruit contain a higher amount of polyphenols, phytosterols, anthocyanins, saponins, triterpenes, amino acids, fatty acids, and minerals.7 It is also rich in flavonoid compounds such as rutin, kaempferol, quercetin, and scopolitin. M. alba proved its efficacy in neuroprotective, immunomodulatory, anticancer, antimicrobial, and antioxidant activities.8 Likewise, another fruit from the same Moraceae family, F. carica, contains numerous phenolics (ferulic, caffeoyl quinic acid, and quercetin glycosides) and organic acids (malic, citric, fumaric, oxalic, quinic, shikimic, and chlorogenic acids). The fruit extract showed its efficacy in antioxidant, anti-inflammatory, anti-ulcerogenic, hepatoprotective, and gastroprotective activities.9

Ginkgo biloba (Ginkgoaceae family) contains different phytoactive compounds such as flavonoids, terpene trilactones, proanthocyanidins, ginkgolic acids, biflavone, and ginkgotoxins. Ginkgo fruits and seed are also used traditionally against various diseases such as asthma, cough, and enuresis.10 The Ginkgo fruits (nuts) are also known to have health benefits for prevention of cancer, cardiovascular, neurological disorder, and photoprotective effect.11,12

Collagenase enzyme is a metalloproteinase which can degrade molecules such as aggrecan, elastin, fibronectin, gelatine, laminin, and collagen.13 Therefore, the agents that inhibit collagenase activity may have beneficial effects to maintain healthy skin by preventing dermal matrix degradation. Here, we investigated the inhibitory activity of combined fruits formulation against collagenase enzyme to elucidate their therapeutic potential against anti-wrinkle activity. In this study, our main objective was to evaluate the antioxidant, anti-collagenase (in vitro), and anti-wrinkle (in vivo) effect of fruit’s extract of four different plant species in combination.

Materials and methods
Sample preparation
The ripened fruits of P. granatum, G. biloba, F. carica, and M. alba were purchased from the local market in their available season in the year 2011. After collection, the samples were air dried (moisture free), grinded to powder, and stored in a refrigerator till used. The air-dried fruit sample (100 g each) was extracted using 70% ethanol at room temperature. The extracts were evaporated in a rotary evaporator at 40°C. The extracted powder samples were combined in equal proportion and used for experiment after dilution for antioxidant and collagenase inhibition activity in vitro.

Topical formulation of fruits extract
Two percent of combined fruit extracts (P. granatum, F. carica, M. alba, and G. biloba) were mixed with a formulation containing water, carbomer, glycerine, disodium EDTA (ethylenediaminetetraacetic acid), methyl paraben, triethanolamine, tocopheryl acetate, polysorbate 60, stearyl alcohol, PEG-100 (polyethylene glycol-100) stearate, sorbitan stearate, caprylic/capric triglyceride, dimethicone, mineral oil, propylparaben, butylene glycol, beeswax, and fragrance. The placebo (control) was identical in composition, except fruits extract.

In vitro antioxidant activity
DPH free radical scavenging assay
The antioxidant activity of extract on the basis of the scavenging activity of the stable 1,1-diphenyl-2-picrylhydrazyl (DPPH) free radical was determined according to the method described by Braca et al,14 with a slight modification. Briefly, a dilution series (three different concentrations) of formulated extract was prepared in a 96-well plate. The reaction mixture consisted of 0.1 mL extract with 0.2 mL DPPH solution (0.15 mM in 80% methanol solution). The mixture was shaken vigorously and left to stand for 30 minutes at room temperature in the dark. Ascorbic acid was taken as positive control. The absorbance of the resulting solution was measured spectrophotometrically at 517 nm and the percent inhibition activity was calculated according to following formula:

\[
\text{Scavenging activity} \% = \left( \frac{A_{\text{sample}} - A_{\text{control}}}{A_{\text{control}}} \right) \times 100
\]

where \(A_{\text{control}}\) is the absorbance of the control reaction and \(A_{\text{sample}}\) is the absorbance in the presence of extract.

\(\text{H}_2\text{O}_2\) scavenging inhibition activity
The scavenging activity of \(\text{H}_2\text{O}_2\) was performed according to the protocol of Sroka and Cisowski.15 Briefly, sample
extract (100 µL) was diluted in different concentrations. To
the sample, H₂O₂ (100 µL), 0.1 M NaCl (100 µL), and 0.1 M
phosphate buffer (700 µL, pH 7.0) were mixed thoroughly
and incubated at 37°C for 20 minutes. Furthermore, 1 mL of
a solution containing phenol red (0.2 g/mL) and horseradish
peroxidase (0.1 mg/mL) was added and mixed thoroughly
before incubated at 37°C for 15 minutes. The absorbance
was taken at 610 nm against a blank after the addition of 1
M NaOH (100 µL) to the incubated solution. The percent-
age of inhibition was calculated according to the following
formula:

\[
% \text{ inhibition} = \frac{A_{\text{blank}} - A_{\text{sample}}}{A_{\text{blank}}} \times 100
\]

where \( A_{\text{control}} \) refers to the control solution without sample (only water) and \( A_{\text{sample}} \) refers to the absorbance with the sample.

**Superoxide inhibition activity**

The superoxide anion (O₂⁻) scavenging activity was mea-
sured according to the method of Nishimiki et al. Briefly,
different concentrations of sample (1 mL) were mixed
with nitro blue tetrazolium solution (156 µM in 100 mM
phosphate buffer, pH 7.4) and 1 mL nicotinamide adenine
dinucleotide (468 µM in 100 mM phosphate buffer, pH 7.4).
The reaction was initiated by adding 100 µL of phenazine
methosulfate (prepared with 100 µM phosphate). The mixture
was incubated at 25°C for 5 minutes and the absorbance
was measured at 560 nm against blank samples. The percentage
inhibition of superoxide radical was calculated using the following
formula:

\[
% = \left( \frac{A_{\text{blank}} - A_{\text{sample}}}{A_{\text{blank}}} \right) \times 100
\]

where \( A_{\text{blank}} \) is the absorbance of the control reaction (without
test sample) and \( A_{\text{sample}} \) is the absorbance of the extracts.

**Collagenase inhibition activity**

Collagenase inhibition activity was performed according
to the protocol of Barrantes and Guinea with a slight
modification. Briefly, a dilution series (different concentra-
tions of 0.5%, 1%, 2.5%, and 5%) of extract (50 µL) was
prepared in a 96-well plate with mixed with 20 µL of type-I
collagen (substrate). Then, a diluted collagenase enzyme
(100 µL, 0.2U mL) was added to each well and the reac-
tion mixtures were incubated for 30 minutes at 37°C. The
final volume was adjusted to 200 µL with 30 µL of buffer.
Negative control was performed with buffer and substrate
but without enzyme. Fluorescence was measured at excita-
tion maxima of 495 nm and emission maxima of 515 nm.
All assays were performed independently in triplicates. The
inhibition percentage was calculated according to the fol-
lowing formula:

\[
\text{Collagenase inhibition activity (％)} = \left( 1 - \frac{S_{abs} - S_{babs}}{C_{abs} - C_{babs}} \right) \times 100
\]

where \( S_{abs} \) is the sample test absorbance, \( S_{babs} \) is the sample blank
absorbance, \( C_{abs} \) is the positive control absorbance, \( C_{babs} \) is the
negative control absorbance.

**Human clinical study (wrinkle area difference, length, depth, and
dermatological (visual) score)**

The study was proposed during October 15, 2012 to
January 15, 2013 in Guangzhou city, Land Proof Test Tech-
nology Co, Ltd, People’s Republic of China. This study was
a randomized, open, single-blinded, placebo-controlled,
observer-blinded study which was approved by GuangDong
light industry association institutional review committee for
human testing. Twenty-one female subjects aged 45–65 years
(without the history of serious diseases or allergic to cos-
metics or pregnant women) participated in the study. The
subjects’ crow’s feet area on both sides (right and left) were
selected in which the wrinkles must not cross each other and
the length of the main wrinkle must be at least 2 cm long. All
subjects gave a written informed consent prior to the study
and evaluated for tolerance. Subjects were treated with 2%
topical formulated fruit extract on one side of the face (crow’s
feet) and with placebo (ingredients without fruit extract) on
the other side twice a day for 58 days. Clinical evaluations
and measurements were performed on D0 (before treatment),
D28, and D56. The effect of extracts on wrinkle was evalu-
ated by using Cutometer MPA 580 (Courage and Khazaka
Electronic, Köln, Germany), which measures skin elasticity,
Visioline VL650 (Courage and Khazaka Electronic), which
measures wrinkle depth, and SILFLO kit (cuDerm corpora-
tion, Dallas, TX, USA). Prior to visual score (dermatological
score) by dermatologist, subjects were acclimatized under a
standard laboratory condition (temperature 22°C±1°C and
humidity 50±3%).

**Statistical analysis**

Statistical analyses were carried out using the SPSS software
(version 11.5; SPSS Inc., Chicago, IL, USA). The differences
among samples were statistically evaluated via one-way
analysis of variance followed by Dunnett’s post hoc test or
Wilcoxon’s test when appropriate. The level of significance was set at $P<0.05$, $P<0.01$, and $P<0.001$. Data are expressed as mean ± standard error.

### Result

**In vitro antioxidant activity**

Ethanolic extracts of four different types of fruits (P. granatum, G. biloba, F. carica, and M. alba) in combined form showed a different pattern of antioxidant activity. The antioxidant efficacy of combined fruit extract in comparison with control (standard compounds) is given in Table 1. The extract showed a higher free radical (DPPH) scavenging activity with the IC$_{50}$ value of 4.24±1.84 µg/mL. This value was very close to ascorbic acid (positive control) used in the experiment, which shows the IC$_{50}$ value of 2.26±0.67 µg/mL. In the hydrogen peroxidation inhibition assay, the extract showed the IC$_{50}$ value of 35.14±2.58 µg/mL and the BHA (positive control) showed the IC$_{50}$ value of 24.69±0.87 µg/mL. In the superoxide inhibition assay, the fruit extract inhibited oxygen radical in a dose-dependent manner. The IC$_{50}$ value of fruit extract was 4.97±1.02 compared to Trolox (positive control) used in the experiment with the value of 27.23±1.05 µg/mL.

**Collagenase inhibition activity**

Figure 1 shows the dose-dependent inhibition of enzymes by the combined fruit extract. The incubation of the enzyme with the fruit extract significantly ($P<0.05$) inhibited the enzyme. A concentration of 5 µg/mL extract showed 67.45% enzyme inhibition, whereas lower concentrations of 0.5, 1, and 2.5 µg/mL fruit extract caused 12.03%, 32.90%, and 55.61% enzyme inhibition, respectively.

**Human clinical study**

We examined the effect of 2% topical formulated fruit cream on the wrinkles of crow’s feet site of the eyes (Figure 2). The treatment for 2% formulated cream for 28 days did not show any significant difference with the placebo. However, treatment for 56 days reduced significantly the percentage of wrinkle depth (Figure 3), length (Figure 4), and area (Figure 5) by 11.5%, 10.07%, and 29.55%, respectively, compared with the placebo. The dermatological scores of the sides treated by the extract containing cream decreased significantly ($P<0.05$) on 56 days with 1.5 fold lower than that of the placebo treatment (Figure 6).

### Discussion

The efficacy of individual plants (P. granatum, G. biloba, F. carica, and M. alba) extract on pharmaceutical application have been evaluated elsewhere. According to our data, the combined fruit’s extract showed a higher antioxidant activity in vitro DPPH, H$_2$O$_2$, and O$_2^-$ model, which was comparable with the positive standard (ascorbic acid, BHA, and Trolox) used in the experiment (Table 1).

According to the published literatures elsewhere, it has been known that the P. granatum fruit (both seed and pills) exhibits a higher antioxidant activity due to the presence of different phenolic compositions such as anthocyanins, punicalagin isomers, and elagic acid. Singh et al reported that the peels and seeds of P. granatum scavenge DPPH free radicals with 81.0% and 23.2% at 50 and 100 µg/mL concentrations of methanolic extract, respectively. The author also reported 51.0% of hydroxyl scavenging activity of the fruit at a concentration of 100 µg/mL.

---

**Table 1 In vitro antioxidant activity of fruits extract**

| Extract/compound | DPPH  | Hydrogen peroxidation | Superoxide | Collagenase inhibition activity (%) |
|------------------|-------|-----------------------|------------|-------------------------------------|
| Sample (fruits) extract | 4.24±1.84 | 35.14±2.58 | 4.97±1.02 | 51.05* |
| Standards Ascorbic acid | 2.26±0.67 | – | – | 29.55* |
| Trolox | – | – | 27.23±1.05 | 29.55* |
| BHA | – | 24.69±0.87 | – | 29.55* |

*Notes: Standard compounds ascorbic acid, BHA, and Trolox were used for comparison. *Average of three determinations. Abbreviations: SD, standard deviation; DPPH, 1,1-diphenyl-2-picrylhydrazyl; BHA, butylated hydroxyanisole.

**Figure 1** Dose-dependent inhibition of collagenase by combined fruits extract. Fluorescence was measured at excitation maxima of 495 nm and emission maxima of 515 nm. The data are representative of three different experiments with similar results. *$P<0.05$ when compared with placebo.
In vitro and in vivo anti-wrinkle activities of combined fruits extract

Morus alba is rich in polyphenolic compounds especially the flavonoids and among the flavonoids quercetin 3,6-malonylglycoside is the most significant component accounting for the antioxidant potential of mulberry plant. Moreover, anthocyanin components such as cyanidin-3-glucoside, cyanidin-3-rutinoside, and stilbene glycoside (mulberroside A) also attribute to the antioxidant activity of M. alba. According to the report by Khan et al, the IC$_{50}$ value of M. alba in the DPPH model was 76.0 µg/mL and the standard (catechin) used in the experiment showed the IC$_{50}$ value

of 27.5 µg/mL. The author also compared the hydroxyl radial scavenging activity of the sample and the standard (BHT), which showed the IC50 value of 177.5 and 8.5 µg/mL, respectively.

*Ficus carica* fruit is characterized by the presence of higher quantities of phenolic acids and has significant antioxidant and anti-inflammatory properties.9 Due to the presence of phenolic acids such as chlorogenic acid, quercetin-3-O-rutinoside (peels), and psoralen (pulp), *Ficus* fruits are utilized for the treatment of skin depigmentation.24 Yang et al25 reported that the methanolic extract of *F. carica* fruit showed the IC50 value of 80.0 µg/mL, whereas the water extract of fruit showed the IC50 value of 720.0 µg/mL in the DPPH model. Similarly, the water extract of the fruit also showed a moderate superoxide radical scavenging activity with the IC50 value of 950.0 µg/mL.

*Ginkgo biloba* extracts rich in flavonoid biflavones and terpene trilactones have been used widely due to the anti-inflammatory effect. In an experiment, Jain et al26 reported that the methanol extract of *P. granatum* alone has the IC50 value of 147.6 mg/mL and that of *G. biloba* was 134 mg/mL in the DPPH model. In the superoxide scavenging activity assay, the IC50 value of *P. granatum* and *G. biloba* was 121.1 and 128.2 mg/mL, respectively. However, in combined formulation, due to the synergistic effects, the IC50 values were increased to 33.5 and 46.39 mg/mL in DPPH and superoxide scavenging model system, respectively.

According to our data, the combined formulated fruit extract showed a much higher rate of inhibition (DPPH and hydroxyl radical scavenging assays) than the aforementioned efficacy of individual plant’s fruit extract (Table 1). In the superoxide inhibition assay, the combined fruit extract showed 5.48-fold higher efficacy than that of Trolox. These higher inhibition activities of the combined formulated fruit extract could be due to the synergistic effect of phytochemicals present in the sample. According to Wagner,3 the higher efficacy of multidrug combination could be due to the increase in the solubility or resorption rate of one of the major constituents present in the extract, or could be due to the antagonistic effects of certain constituents against some toxic compounds.

It has been reported that collagenase cleaves the amino acid bond of collagen and breaks down the collagen and elastin which possibly leads to the prolonged skin damage or wrinkle formation.27 To prevent the skin from aging or wrinkles, natural collagenase inhibitors from plant is desirable. Naturally, plant phenolic compounds have been known to inhibit the collagenase activity. In previous findings, it has been reported that the butanol fraction of *G. biloba* seed, *P. granatum* (fruit), and *M. alba* (whole plant extract) inhibited up to 50.8%, 4.4%, and 19.5% of MMP-9.28 Boiled water extract of *P. granatum* fruit exhibited both the collagenase (11%) and elastase (14.64%) inhibition activity.29 According to our research, the combined formulation of fruits exhibited comparatively higher inhibition
of collagenase (shown in a dose-dependent manner in Figure 1). A concentration of 5 μg/mL fruit extracts showed 67.45% enzyme inhibition. This higher activity of collagenase inhibition by combined fruits may be due to the conformational change in collagenase induced by the synergistic effect of polyphenols.30

We examined a human in vivo clinical study focusing on the reduction of wrinkle (area, depth, and length) located around the eyes in crown’s feet region (Figure 2). According to the data, the significant (P<0.05, P<0.01) reduction of wrinkle (depth, length, and area) was observed after 56 days of application. Our in vivo data are based on observation; therefore, further molecular work is needed to understand the proper mechanism of anti-wrinkle activity of topically formulated fruit extract. According to the literature elsewhere, it is known that the reactive oxygen species directly act on fibroblasts and then reduce collagen production.31 Therefore, it can be speculated that the anti-wrinkle activity of fruit extract could be due to the presence of higher radical scavenging activity which quench the free radicals from the skin and thereby protect the collagen from degradation. And also, the phytochemical may have possible interactions with the special enzymes, mediators in the signal transduction pathway.3 For example, the anti-wrinkle activity of formulated fruit extract may be due to the suppressive effect of some phytochemicals on C-Jun N-terminal kinase or MMPs (MMP-1, MMP-3, and MMP-9) which activates due to oxidative stress.32

In conclusion, the combined formulation of P. granatum, G. biloba, F. carica, and M. alba fruits extract provides excellent antioxidative and anti-collagenase activity in vitro and also showed a significant effect on the anti-wrinkle activity in vivo. Overall, the results obtained in this research contributed to elucidate the possible effects on the anti-wrinkle prospects of skin with combined topical formulation of plant fruits extract.
