COUNTING IN HYPERBOLIC SPIKES: THE DIOPHANTINE ANALYSIS OF MULTIHOMOGENEOUS DIAGONAL EQUATIONS

VALENTIN BLOMER AND JÖRG BRÜDERN

Abstract. A method is described to sum multi-dimensional arithmetic functions subject to hyperbolic summation conditions, provided that asymptotic formulae in rectangular boxes are available. In combination with the circle method, the new method is a versatile tool to count rational points on algebraic varieties defined by multi-homogeneous diagonal equations.

1. Introduction

Our main concern in this memoir is with the distribution of rational points on a class of multiprojective varieties that we now introduce. Let \( d, k, n \) be natural numbers with \( n \geq 2 \). Then, whenever \( a_0, a_1, \ldots, a_n \) are non-zero integers, the equation

\[
\sum_{j=0}^{n} a_j (x_{1,j}x_{2,j} \cdots x_{k,j})^d = 0
\]

is homogeneous of degree \( d \) in the variables \( x_i = (x_{i,0}, \ldots, x_{i,n}) \), and therefore defines a variety \( \mathcal{V} \) in \( \mathbb{P}^n(\mathbb{Q})^k \). Its rational points are in 1-to-2 \( k \) correspondence to solutions of (1.1) in primitive vectors \( x_i \in \mathbb{Z}^{n+1} \), with each \( x_i \) unique up to sign. Since the norm

\[
|x_i| = \max_{0 \leq j \leq n} |x_{i,j}|
\]

is independent of the ambiguous sign, we may define the height of the rational point as

\[
(\ell |x_1| |x_2| \cdots |x_k|)^{n+1-d}.
\]

Motivated by an influential set of conjectures put forward by Manin (see [10]), Batyrev and Tschinkel [11] and Peyre [13], we seek to establish an asymptotic formula for the number \( N(B) \) of rational points on \( \mathcal{V} \) with \( x_{i,j} \neq 0 \) for all \( 1 \leq i \leq k, 0 \leq j \leq n \) and height not exceeding \( B \). Our methods prove successful whenever \( n \) is sufficiently large, the threshold being determined by our understanding of moments of classical Weyl sums. In this context, let \( n_0(d) \) denote the smallest even natural number with the property that for any positive real number \( \varepsilon \) one has

\[
\int_0^1 \left| \sum_{1 \leq x \leq P} e^{2\pi i \alpha x^d} \right|^{n_0(d)} \, d\alpha \ll P^{n_0(d)-d+\varepsilon}.
\]

The integral here has an interpretation as the number of solutions of an underlying diophantine equation, and in this way one finds that the integral is bounded below by \( P^{n_0/2} \).

Key words and phrases. Hyperbola method, arithmetical functions, rational points, Hardy-Littlewood method.

First author supported by the Volkswagen Foundation and a Starting Grant of the European Research Council.
This implies that \( n_0(d) \geq 2d \). It is also immediate that \( n_0(1) = 2 \) and \( n_0(2) = 4 \), and as an averaged version of Hardy and Littlewood’s well-known conjecture \( K \), it is expected that \( n_0(d) = 2d \) holds for all \( d \). The current records are

\[
\begin{align*}
n_0(3) & \leq 8, \\
n_0(4) & \leq 16, \\
n_0(5) & \leq 28, \\
n_0(6) & \leq 44,
\end{align*}
\]

see [18, Lemma 2.5] for \( d = 3 \) or 4, and [22] for \( d = 5 \) and 6. When \( d \) is large, one has \( n_0(d) \leq 1.543d^2 \) (see [22]).

**Theorem 1.1.** Let \( d, k, n \) be natural numbers with \( n \geq n_0(d) \). Let \( a_0, \ldots, a_n \) be non-zero integers. Then, there are a positive number \( \delta \), a non-negative number \( C \), and a monic polynomial \( Q \in \mathbb{R}[X] \) of degree \( k - 1 \) such that

\[
N(B) = CBQ(\log B) + O(B^{1-\delta}).
\]

Moreover, the number \( C \) is positive if and only if the equation

\[
a_0y_0^d + a_1y_1^d + \ldots + a_ny_n^d = 0
\]

has non-trivial solutions in real numbers and in \( p \)-adic numbers, for all primes \( p \).

The constant \( C \) is a product of local densities and coincides with the predictions stemming from a formal use of the Hardy-Littlewood method. We shall make this more precise at the very end of this paper.

The counting function \( N(B) \) is blind for points on coordinate hyperplanes because the intersection of the union of them with \( \mathcal{V} \) contains abnormally many points of small height. To see this, first suppose that \( k \geq 3 \), choose

\[
x_1 = (1, 0, 0, \ldots, 0), \quad x_2 = (0, 1, 0, \ldots, 0)
\]

and \( x_i = x_2 \) for \( 3 \leq i \leq k - 1 \). Then any primitive \( x_k \in \mathbb{Z}^{n+1} \) yields a point \( (x_1, \ldots, x_k) \) on \( \mathcal{V} \), and there are \( \gg B^{(n+1)/(n+1-d)} \) such points where the height does not exceed \( B \). Similarly, when \( k = 2 \), choose \( (z_1, \ldots, z_n) \in \mathbb{Z}^n \) primitive and

\[
x_1 = (1, 0, 0, \ldots, 0), \quad x_2 = (0, z_1, \ldots, z_n)
\]

to find \( B^{n/(n+1-d)} \) points on \( \mathcal{V} \) with height not exceeding \( B \). When \( d > 1 \), the order of magnitude here is still bigger than the leading term in Theorem 1.1.

Only for very few choices for the parameters \( d, k, n \) the conclusions in Theorem 1.1 are already known. Of course when \( k = 1 \), the equation (1.1) becomes a standard diagonal equation, and the height (1.2) reduces to the naive height. In this case, an asymptotic evaluation of \( N(B) \) is possible by classical versions of the circle method, and there is an established theory that has been developed in parallel with the asymptotic formula in Waring’s problem (see Vaughan [18] and Wooley [21, 22] for an account), and to which we have nothing to add. In contrast, all cases where \( k \geq 3 \) seem to be the first results at all about this family of varieties. In fact, there are remarkably few examples of multiprojective varieties where the rational points have been counted satisfactorily with respect to the anticanonical height (see the authors’ note [3], Le Boudec [5], and Schindler [15] for recent efforts in a biprojective setting). For the varieties under consideration, this height is given by (1.2). It is the geometrically most natural and the analytically most challenging choice. Indeed, if one considers (1.1) as an affine equation and cuts out a portion of its integral solutions by a constraint like \( |x_1| |x_2| \ldots |x_k| \leq X \), then the underlying surface has hyperbolic spikes where standard counting routines tend to deny service. In the special case \( k = 2, d = 1 \), a number of devices have been developed to overcome this difficulty.
Bump [7, Chapter 5] and Vinogradov and Takhtadzhyan [19] independently observed that there is a natural bijection between the rational points on
\begin{equation}
  x_0y_0 + x_1y_1 + x_2y_2 = 0
\end{equation}
and the cosets of $\text{SL}_3(\mathbb{Z})$ factored by the group of upper triangular unipotent matrices. With this in hand, the Dirichlet series
\begin{equation}
  \sum_{x,y} (x_0^2 + x_1^2 + x_2^2)^{-s} (y_0^2 + y_1^2 + y_2^2)^{-s},
\end{equation}
with the sum running over primitive solutions $x \in \mathbb{Z}^3, y \in \mathbb{Z}^3$ of (1.5), can be expressed in terms of the minimal parabolic Eisenstein series for $\text{GL}_3$, and one finds that the analytic function defined by (1.6) extends to a meromorphic function on the whole complex plane. In $\text{Re } s > \frac{1}{2}$ its only poles are at $s = 1$ and $s = \frac{3}{4}$ (see [7, Theorem 7.1]). Some mundane analytic number theory then yields a version of Theorem 1.1 for the equation (1.5), but with the euclidean norm used in the definition of height. This approach rests on the observation that the biprojective variety defined by (1.5) carries a natural group structure. A similar line of thought is present in much work related to the Manin-Peyre conjecture, following the pivotal analysis of flag varieties by Franke, Manin and Tschinkel [10]. In the higher degree cases of Theorem 1.1, however, an analogous theory is not available, and we will have to turn to other methods. Thunder [17] recovered the results of Franke, Manin and Tschinkel by using ideas from the geometry of numbers, but again it appears difficult to apply his method to the higher degree cases in Theorem 1.1. For another method to count primitive solutions of (1.5) see Browning [6].

It seems natural to approach the equation (1.5) directly by the circle method. A first attempt was made by Robbiani. He also studied the bilinear case $d = 1, k = 2$ and used a version of the circle method that relies on an identity of Duke, Friedlander and Iwaniec [9], and that Heath-Brown [11, 12] applied to the analytic theory of quadratic and cubic forms. Robbiani’s result only covers the cases $n \geq 3$, and does not easily generalise to higher degree. A more classical approach has been engineered by Spencer [16]. His method is in the spirit of Vinogradov’s description of the circle method. Spencer concentrates on the equation (1.5) where the height constraint $|x_iy_j|^2 \leq B$ ($0 \leq i, j \leq 2$) prevents the generating function from immediate factorisation. This causes considerable complication in detail. As Spencer shows, it is possible to disentangle the height condition with an appropriate Fourier analysis. However, certain difficulties remain, and if $N^*(B)$ denotes the function $N(B)$ in the special case (1.5), then Spencer only shows that $N^*(B) = CB \log B + O(B)$, with some unspecified constant $C$.

In this memoir we propose another approach to problems in this class that is based on a straightforward use of the circle method on the one hand, and on the other on a version of Dirichlet’s method of the hyperbola in weighted setting. Once the machinery is set up, it delivers Theorem 1.1 with great ease, and with a single treatment for all choices of the parameters $k, d$ and $n$. It transpires that the method should be widely applicable in related contexts. With a careful use of the ideas contained in this paper, the conclusions in Theorem 1.1 for the equation (1.5) can be refined to
\begin{equation}
  N^*(B) = \frac{33 - 6\zeta(2)}{8\zeta(2)\zeta(3)} B \log B + AB + O(B^{7/8}(\log B)^3)
\end{equation}
where $A$ is a suitable real number. We do not present the details here but refer to our forthcoming article [4]. Another class of varieties where our methods can be applied is related to Vinogradov’s mean value theorem. While the diagonal equation (1.4) can be
viewed as the “germ” that produces \((1.1)\) by inserting suitable products, we now consider a system
\[
a_{i_0} y_0^l + a_{i_1} y_1^l + \ldots + a_{i_n} y_n^l = 0 \quad (1 \leq l \leq d)
\]
with integer coefficients \(a_{i_j}\) as the germ. Then, the equations
\[
\sum_{j=0}^n a_{i,j}(x_{i,j} x_{2,j} \cdots x_{k,j})^l = 0 \quad (1 \leq l \leq d)
\]
are homogeneous in the variables \(x_i = (x_{i,0}, \ldots, x_{i,n})\), and therefore the system defines another variety in \(\mathbb{P}^n(\mathbb{Q})^k\). As before, its rational points correspond to solutions of \((1.8)\) in primitive vectors \(x_i \in \mathbb{Z}^{n+1}\), with each \(x_i\) unique up to sign. The height of a rational point is now defined by \((|x_i| |x_2| \cdots |x_k|)^{n+1-\frac{d}{2}}\). Let \(N'(B)\) denote the number of rational points on the multiprojective variety defined by \((1.8)\) with height not exceeding \(B\) and with \(x_{i,j} \neq 0\) for \(1 \leq i \leq k\) and \(0 \leq j \leq n\). There is then a result for \(N'(B)\) that is very similar to Theorem 1.1. Again, our method requires nearly optimal control on a certain moment of a suitable Weyl sum. Let \(n_1(d)\) denote the smallest even natural number with the property that for any positive real number \(\varepsilon\) one has
\[
\int_{[0,1]^d} \left| \sum_{1 \leq z \leq P} 2^{2\pi i (\alpha_1 z + \ldots + \alpha_d z^d)} \right|^{n_1(d)} d\alpha << P^{n_1(d)-\frac{d}{2}d(d+1)+\varepsilon}.
\]

**Theorem 1.2.** Let \(d, k, n\) be natural numbers with \(n \geq n_1(d)\). Let \(a_{i,j}\) \((1 \leq l \leq d, 0 \leq j \leq n)\) be non-zero integers. Then, there are a positive number \(\delta\), a non-negative number \(D\), and a monic polynomial \(R \in \mathbb{R}[X]\) of degree \(k-1\) such that
\[
N'(B) = DBR(\log B) + O(B^{1-\delta}).
\]
Moreover, the number \(D\) is positive if and only if the system of equations \((1.7)\) has non-trivial solutions in real numbers and in p-adic numbers, for all primes \(p\).

There is a widely held belief that \(n_1(d) = d(d+1)\) should hold for all \(d \in \mathbb{N}\). This is trivial for \(d = 1\) and well-known for \(d = 2\) (see, for example, the discussion in [2]). Very recently Wooley [23] proved \(n_1(3) = 12\). With the arrival of efficient congruencing in epoch-making work of Wooley [20], early upper bounds on \(n_1(d)\) due to Vinogradov and others remain of historical value. Progress with the new methods is still ongoing, but we now know that [22]
\[
d(d+1) \leq n_1(d) \leq 2d(d-1) + 2.
\]

Our proof of Theorem 1.1 begins with counting primitive solutions to \((1.8)\) inside boxes \(|x_i| \leq X_i\) \((1 \leq i \leq k)\). Irrespective of the shape of the box, connaisseurs of the circle method will find the task of supplying an asymptotic formula for this count fairly routine. As a second step, one needs to express \(N(B)\) in terms of the count in boxes. More precisely, let \(m \in \mathbb{N}^k\), and let \(\theta(m)\) denote the number of primitive \(x_i \in \mathbb{Z}^{n+1}\) satisfying \((1.8)\) and \(|x_i| = m_i\), \(x_{i,j} \neq 0\) \((1 \leq i \leq k, 0 \leq j \leq n)\). Then, according to the opening paragraph of this memoir,
\[
N(B) = 2^{-k} \sum_{m_1 m_2 \ldots m_k \leq B^{1/(n+1-d)}} \theta(m),
\]
and one desires to deduce an asymptotic formula for this sum from related formulæ for
\[
(1.10) \quad \Theta(X_1, \ldots, X_k) = \sum_{m_1 \leq X_i, \ 1 \leq i \leq k} \theta(m)
\]
that are the relevant sums for the count in boxes. The transition from (1.10) to (1.9)
can be performed subject to very mild and general conditions, the actual definition of \( \theta \nolimits \)
being irrelevant for this part of the argument. Hence, apart from the specific applications
to problems such as those considered in Theorems 1.1 and 1.2 we provide a method to
evaluate divisor sums with weights similar to the one in (1.9). This tool should be of
some utility in the analytic theory of numbers, and certainly constitutes the most novel
feature of our analysis. Precise statements and a discussion of the underlying ideas of
the transition process from (1.10) to (1.9) are deferred to next section that can be read
independently of the rest of the paper. In Section 3 we study Weyl sums over products
in preparation for the circle method work in Section 4. Each of these sections is equipped
with a short introduction to the respective subject. In the short final section, Theorem
1.1 is deduced from the main conclusions formulated in Sections 2 and 4. Not only in
structure but up to fine detail, the proof of Theorem 1.2 is very similar and therefore
omitted.

**Notation.** Owing to the wide range of topics discussed in this paper, a completely
consistent notation would be in conflict with the various traditions involved. However,
most of the notation used is standard. Small italics usually denote integers, letters from
the middle of the alphabet like \( k \), \( n \) or \( m \), but also \( d \) are natural numbers, and \( j \) is a non-negative integer. The letter \( p \) is reserved for primes. Capital italics
\( N, P, B, U, V, W, X, Y \) and \( Z \) are used for the main parameters, and statements involving such a parameter are
valid for its positive values exceeding 1. Real variables are denoted by small greek letters,
but also by \( t \). These conventions apply with or without subscript whenever the symbol
does not obviously denote a function.

The letter \( \varepsilon \) always denotes a positive real number, and whenever \( \varepsilon \) occurs in a statement
it is asserted that the statement is valid for all positive numbers \( \varepsilon \). Constants implicit in
Landau or Vinogradov symbols may depend on \( \varepsilon \). Note that this convention allows us to
conclude from \( A \ll P^\varepsilon \) and \( B \ll P^\varepsilon \) that \( AB \ll P^\varepsilon \), for example.

We make use of vector notation frequently, with some uncommon elements now to be
described. Boldface denotes vectors, with entries written in the corresponding italic font,
and the dimension may vary from one occurrence to the next. When \( \mathbf{x} = (x_1, \ldots, x_r) \),
\( \mathbf{y} = (y_1, \ldots, y_s) \) and \( \mathbf{z} = (z_1, \ldots, z_t) \), we use \( (\mathbf{x}, \mathbf{y}, \mathbf{z}) \) to denote the \( r + s + t \)-tuple
\( (x_1, \ldots, x_r, y_1, \ldots, y_s, z_1, \ldots, z_t) \). Also, we will have to permute the entries of a vector.
Let \( S_k \) denote the symmetric group on \( k \) elements. Then, for \( \sigma \in S_k \) and \( \mathbf{x} \in \mathbb{R}^k \), write
\[
\sigma \mathbf{x} = (x_{\sigma(1)}, \ldots, x_{\sigma(k)}).
\]
For functions \( H \) defined on \( \mathbb{N}^k \) or \( [1, \infty)^k \), we define
\[
H_\sigma(\mathbf{x}) = H(\sigma^* \mathbf{x}).
\]
Inequalities between vectors are to be interpreted as the system of inequalities given by
the components. Thus, for \( \mathbf{x}, \mathbf{X} \in \mathbb{R}^k \), the system of \( k \) inequalities \( x_j \leq X_j \) (\( 1 \leq j \leq k \)) is
abbreviated to \( \mathbf{x} \leq \mathbf{X} \). Whenever \( X_j \geq 1 \) for all \( j \) with \( 1 \leq j \leq k \), we write
\[
(\mathbf{X}) = X_1 X_2 \ldots X_k.
\]

The number of divisors of \( n \) is denoted by \( \tau(n) \). Euler’s totient function is \( \varphi(n) \), and
the Möbius function is \( \mu(n) \). The highest common factor of \( a \) and \( b \) is \((a; b)\). We put
\( e(\alpha) = \exp(2\pi i \alpha) \), and denote Riemann’s zeta function by \( \zeta(s) \).
2. The hyperbola method

2.1. The transition theorem. Not only a few problems in the theory of numbers depend implicitly or explicitly on the asymptotic evaluation of the sum

\[ \Upsilon(N) = \sum_{u_1 u_2 \ldots u_k \leq N} h(u). \]

Here the dimension \( k \) and the arithmetical function \( h : \mathbb{N}^k \to \mathbb{C} \) are intrinsic to the application at hand. Perhaps the most familiar cases are the divisor problems of Dirichlet and Piltz where one chooses \( h(u) = 1 \). As we have indicated in the introductory section of the present communication, the counting problems discussed in Theorems 1.1 and 1.2 also reduce to sums of the type \( (2.1) \). Yet, a successful treatment of the cognate box sums

\[ H(X_1, \ldots, X_k) = \sum_{1 \leq x_j \leq X_j, 1 \leq j \leq k} h(x) \]

is often easier, in particular in cases where \( h(u) \) is the number of solutions of a certain diophantine system. Typically, the condition on the product of the variables \( u_1 u_2 \ldots u_k \) in \( (2.1) \) will be in conflict with a direct use of the Hardy-Littlewood method for the diophantine problem at hand.

Whenever the evaluation of the box sums is within the compass of existing technology, one is led to the question whether suitable asymptotic formulae for \( (2.2) \) contain sufficient information to deduce an allied formula for \( \Upsilon(N) \). We shall provide an affirmative answer when \( h \) takes real non-negative values only, and when the leading term in the asymptotic formula for \( H(X) \) is a pure power of \( X_1 X_2 \ldots X_k \). These conditions are not infrequently met in practice, and Theorem 2.1 below should be useful in areas other than those discussed in this paper. However, it should be noted that the conditions on \( h \) formulated in the preamble to Theorem 2.1 have been tuned for our immediate needs. The underlying arguments work in broader generality. For example, if the leading term in an asymptotic formula for \( H(X) \) contains logarithms, these may be accommodated by the method now to be described. For another development of our ideas, see Schindler [15].

We begin by introducing the class of functions \( h \) to which our theory applies. Fix positive real numbers \( \alpha, c, \delta \) with \( \delta < \min(1, \alpha) \). A set \( \mathcal{H} \) of arithmetical functions \( h : \mathbb{N}^k \to [0, \infty) \) will be referred to as a \( (\alpha, c, \delta) \)-family, provided the two further conditions (II) and (III) are satisfied:

\[ \text{(II)} \quad \text{For } h \in \mathcal{H} \text{ and } r \in \mathbb{N} \text{ with } 1 \leq r \leq k - 1, \text{ there exists an arithmetical function } c_{h, r} : \mathbb{N}^r \to [0, \infty) \text{ such that for any } u \in \mathbb{N}^r \text{ the asymptotic formulae} \]

\[ \sum_{v \leq u} h(u, v) = c_{h, r}(v)^\alpha + O((v)^\alpha (\min_{1 \leq j \leq k} V_j)^{-\delta}) \]

hold uniformly for \( h \in \mathcal{H} \), \( V_j \geq 1 \) and \( |u| \leq \langle v \rangle^\nu \),
(III) For all \( h \in \mathcal{H} \) and \( \sigma \in S_k \), one has \( h_\sigma \in \mathcal{H} \).

Note that the condition (I) is symmetric with respect to the indices \( 1 \leq j \leq k \) whereas (II) alone is not. However, by (III), one may apply (II) to \( h_\sigma \), for any \( \sigma \in S_k \). Hence, one may choose any \( r \) indices and sum \( h(x) \) over the corresponding variables. There is then an asymptotic formula for this sum, similar to the one in (II). Notice also that (I) can be interpreted as the case \( r = 0 \) of (II).

We are ready to announce the principal result of this chapter.

**Theorem 2.1.** Let \( k \geq 2 \), and let \( \mathcal{H} \) be an \((\alpha,c,D,\nu,\delta)\)-family of arithmetical functions \( h : \mathbb{N}^k \to [0,\infty) \). For any \( h \in \mathcal{H} \), let \( \Upsilon(N) \) be defined by (2.1). There exists a positive number \( \eta \) with the property that for any \( h \in \mathcal{H} \) there is a polynomial \( P_h \in \mathbb{R}[x] \) of degree at most \( k - 2 \) such that the asymptotic formula

\[
\Upsilon(N) = N^\alpha \left( c_h \frac{O^{k-1}}{(k-1)!} (\log N)^{k-1} + P_h(\log N) \right) + O(N^{\alpha-\eta})
\]

holds uniformly in \( h \in \mathcal{H} \).

The proof of Theorem 2.1 produces an explicit value for \( \eta \) in terms of \( k, \alpha, c, D, \nu, \delta \), but it will not be very large, as part of the argument is based on induction on \( k \). Therefore no attempt has been made to record the optimal value for \( \eta \) that our methods could establish.

In the next section, we begin by observing a certain rigidity within the functions \( c_{h,l} \) in (II). Then, in the following three sections, we collect several estimates of preparatory character. Some of the asymptotic relations obtained here may be of independent interest.

We highlight the light-weight version of Theorem 2.1 in Theorem 2.7 below. The main argument leading to a proof of Theorem 2.1 is presented in the closing section.

2.2. Families of arithmetical functions.

We begin our discussion with a rough yet useful estimate.

**Lemma 2.2.** Let \( \mathcal{H} \) denote a family satisfying condition (I) with respect to \((\alpha,c,\delta)\). Then, uniformly in \( h \in \mathcal{H} \), one has \( h(u) \ll \langle u \rangle^\alpha \).

**Proof.** This is immediate from (I), on taking \( X = u \).

The principal observation in this section is that the functions \( c_{h,l} \) associated with an \((\alpha,c,D,\nu,\delta)\)-family form another such family. The following lemma makes this precise.

**Lemma 2.3.** Let \( \mathcal{H} \) be an \((\alpha,c,D,\nu,\delta)\)-family of arithmetical functions \( h : \mathbb{N}^k \to [0,\infty) \). Then, for any \( 1 \leq l \leq k - 1 \), the set of functions \( c_{h,l} : \mathbb{N}^l \to [0,\infty) \) with \( h \in \mathcal{H} \) forms an \((\alpha,c,D,1,\delta)\)-family, and one has

\[
\sum_{y \leq Y} c_{h,l}(y) = c_h(Y)^\alpha + O(\langle Y \rangle^\alpha (\min Y_j)^{-\delta}).
\]

**Proof.** We launch the proof with the demonstration of (2.4). In the interest of brevity, write \( m = k - l \). Let \( Z \geq 1 \), and put \( Z = (Z,\ldots,Z) \in \mathbb{R}^m \). Then, as a special case of (II), the asymptotic relation

\[
\sum_{y \leq Y} h(y,z) = c_{h,l}(y) Z^{\alpha m} + O(Z^{\alpha m-\delta} |y|^D)
\]
holds uniformly for all \( y \in \mathbb{N}^l \) with \(|y| \leq Z^{m\nu} \). This may be summed over a box. Note that \( m \geq 1 \), so that whenever \( Y \in \mathbb{R}^l \) satisfies \(|Y| \leq Z^\nu \), one certainly has
\[
\sum_{y \leq Y} \sum_{z \leq Z} h(y, z) = Z^{am} \sum_{y \leq Y} c_{h,l}(y) + O(\langle Y \rangle^{D+1} Z^{am-\delta}).
\]
On the other hand, the sum on the left may be evaluated by (I). For \( Z \geq |Y| \), this yields
\[
\sum_{y \leq Y} \sum_{z \leq Z} h(y, z) = c_h(Y)^\alpha Z^{am} + O(Z^{am} \langle Y \rangle^\alpha (\min Y_j)^{-\delta}).
\]
Divide by \( Z^{am} \) and recall that \( \nu \leq 1 \) to conclude from the last two formulae that for \( Z \geq |Y|^{1/\nu} \) one has
\[
\sum_{y \leq Y} c_{h,l}(y) = c_h(Y)^\alpha + O(\langle Y \rangle^\alpha (\min Y_j)^{-\delta}) + O(|Y|^{D+1} Z^{-\delta}).
\]

With \( Z \to \infty \), the asymptotic formula (2.4) follows. In particular, this verifies condition (I) for the family \( c_{h,l} \). Note that the implicit constant in (2.4) is inherited from the conditions (I) and (II) for the family \( \mathcal{H} \), and is therefore uniform in \( h \).

Next, we establish (II). It will be appropriate to adopt the notation from the previous argument. In addition, let \( 1 \leq r \leq l - 1 \) and \( u \in \mathbb{N}^r, v \in \mathbb{N}^{l-r} \). We choose \( y = (u, v) \) in (2.4) and sum over a box for \( v \). Then, provided that \(|u| \leq Z^{m\nu}, |V| \leq Z^{m\nu} \), one finds that
\[
\sum_{v \leq V} \sum_{z \leq Z} h(u, v, z) = Z^{am} \sum_{v \leq V} c_{h,r}(u, v) + O(|u|^D \langle V \rangle^{D+1} Z^{am-\delta}).
\]
Alternatively, one may use (II) to evaluate the left hand side above. When \( |V| \leq Z \) and \(|u| \leq \langle V \rangle^{\nu} Z^{m\nu} \), this yields
\[
\sum_{v \leq V} \sum_{z \leq Z} h(u, v, z) = c_{h,r}(u) \langle V \rangle^\alpha Z^{am} + O(|u|^D \langle V \rangle^\alpha Z^{am} (\min V_j)^{-\delta}).
\]

One may now proceed as before: a comparison of the last two displays delivers the preliminary estimate
\[
\sum_{v \leq V} c_{h,l}(u, v) = c_{h,r}(u) \langle V \rangle^\alpha + O(|u|^D \langle V \rangle^\alpha (\min V_j)^{-\delta}) + O(|u|^D \langle V \rangle^{D+1} Z^{-\delta}),
\]
subject to the lower bounds on \( Z \) mentioned earlier. With \( Z \to \infty \), the term on the far right disappears, and any \( u \) satisfies \(|u| \leq Z^{m\nu} \) when \( Z \) is large enough. This gives
\[
\sum_{v \leq V} c_{h,l}(u, v) = c_{h,r}(u) \langle V \rangle^\alpha + O(|u|^D \langle V \rangle^\alpha (\min V_j)^{-\delta})
\]
uniformly in \( u \). This proves (II) for \( c_{h,l} \) in place of \( h \), and with \( \nu = 1 \). Moreover, the last estimate is uniform with respect to \( h \in \mathcal{H} \) because the implicit constant can be traced back to the one in (II). Note the recurrent appearance of \( c_{h,r} \) on the right hand side.

Finally, we have to check the condition (III). Let \( \pi \in S_l \) be a permutation of \( \{1, \ldots, l\} \), and let \( \sigma \in S_k \) be a permutation of \( \{1, \ldots, k\} \) with \( \sigma(j) = \pi(j) \) for \( 1 \leq j \leq l \). Then, by (II), it is immediate that \( (c_{h,l})_{\pi} = c_{h,s,l} \), which confirms (III), completing the proof of the lemma.

Let \( \mathcal{H} \) be an \((\alpha, c, D, \nu, \delta)\)-family of arithmetical functions defined on \( \mathbb{N}^k \), and let \( 1 \leq l \leq k - 1 \). For \( h \in \mathcal{H} \), one may fix \( l \) of the variables and consider \( h \) as a function on \( \mathbb{N}^{k-l} \). This process yields another family of functions with similar properties. More
precisely, choose a real number $A \geq \alpha$ and consider, for any $h \in \mathcal{H}$ and $w \in \mathbb{N}_l$, the function

$$g = g_{h, w} : \mathbb{N}_k^l \to [0, \infty), \quad y \mapsto \langle w \rangle^{-A} h(w, y).$$

Let $\mathcal{H}_l$ denote the set of all these functions. Since $\mathcal{H}$ satisfies (III), the same is true of $\mathcal{H}_l$.

**Lemma 2.4.** Let $\mathcal{H}$ and $l$ be as above, and suppose that $A \geq D + (k + 1)\alpha + \nu^{-1}(1 + \alpha)$. Then, for sufficiently large $c'$, the set $\mathcal{H}_l$ is an $(\alpha, c', D, \nu, \delta)$-family.

**Proof.** By Lemma 2.3 we may apply Lemma 2.2 to $c_{h, l}$ in place of $h$. This yields the bound

$$\langle w \rangle^{-\alpha} c_{h, l}(w) \ll 1.$$  \hfill (2.6)

We now proceed to show that uniformly for $h \in \mathcal{H}$ and $w \in \mathbb{N}_l$, one has

$$\sum_{y \leq Y} \frac{h(w, y)}{\langle w \rangle^A} = \frac{c_{h, l}(w)}{\langle w \rangle^A} \langle Y \rangle^\alpha + O(\langle Y \rangle^\alpha (\min Y_j)^{-\delta}).$$  \hfill (2.7)

Once this is established, one obtains (I) for $g_{h, w}$, with $\langle w \rangle^{-A} c_{h, l}(w)$ in the role of $c_h$, and since $A \geq \alpha$, the existence of $c'$ is a consequence of (2.6).

For $|w| \leq \langle Y \rangle^\nu$, one notes that $A \geq D$ to realize that the asymptotic formula (2.7) is a weakened form of (II). Thus, it suffices to confirm (2.7) when $|w| > \langle Y \rangle^\nu$. In this case, we apply (2.6) to see that

$$c_{h, l}(w) \ll \langle w \rangle^{-A} \langle Y \rangle^\alpha \ll 1.$$  

Similarly, by Lemma 2.2

$$\sum_{y \leq Y} \frac{h(w, y)}{\langle w \rangle^A} \ll (\langle w \rangle^{-A} \langle Y \rangle^{\alpha+1}) \ll 1.$$  \hfill (2.7)

Since $\delta \leq \min(1, \alpha)$, one concludes that the two explicit terms in (2.7) are both bounded above by $O(\langle Y \rangle^\alpha (\min Y_j)^{-\delta})$. In particular, this proves (2.7).

The proof of (II) for $\mathcal{H}_l$ is very similar. Let $1 \leq r \leq k - l - 1$, and $v \in \mathbb{N}_r$. We need to confirm that whenever $|v| \leq \langle Z \rangle^\nu$, one has

$$\sum_{z \leq Z} \frac{h(w, v, z)}{\langle w \rangle^A} = \frac{c_{h, l+r}(w, v)}{\langle w \rangle^A} \langle Z \rangle^\alpha + O(\langle Z \rangle^\alpha (\min Z_j)^{-\delta}|v|^D).$$  \hfill (2.8)

As before, we begin with the case where $|w| \leq \langle Z \rangle^\nu$. Here, it suffices to recall that $A \geq D$ which implies that $(\langle w, v \rangle|^D \langle w \rangle^{-A} \leq |v|^D$. Hence, in this case (2.8) is immediate from (II).

When $|w| > \langle Z \rangle^\nu$, one uses Lemma 2.2 to deduce that

$$\sum_{z \leq Z} \frac{h(w, v, z)}{\langle w \rangle^A} \ll \langle w \rangle^{-A} \langle v \rangle^\alpha \langle Z \rangle^{\alpha+1} \ll 1,$$

and a similar but simpler estimation gives

$$\frac{c_{h, l+r}(w, v)}{\langle w \rangle^A} \langle Z \rangle^\alpha \ll 1.$$  

Now (2.8) follows as above.

We have already remarked that $\mathcal{H}_l$ satisfies (III). The proof of Lemma 2.4 is complete.
2.3. Preparatory lemmata. Before we may announce our first estimate, we must introduce some more notation. In order to avoid repetitions comments concerning uniformity of implicit constants, we remark that for the remainder of this chapter, these constants will depend on an auxiliary non-negative integer \( j \), the dimension \( k \), the family \( H \), and on \( \varepsilon \) where appropriate. In particular, the constants depend on the parameters \( \alpha, c, D, \nu, \delta \).

It is relevant to note, however, that these constants will not depend on the individual \( h \in H \).

Now let
\[
\Delta^{(k)} = \{ t \in \mathbb{R}^k : 1 < t_1 < t_2 < \ldots < t_k \}, \quad \Delta^{(k)}(X) = \{ t \in \Delta^{(k)} : t_k \leq X \}.
\]

The next lemma evaluates the integral
\[
I_{h,j}(X) = \int_{\Delta^{(k)}(X)} \frac{(\log(t))^j}{t^{\alpha+1}} \sum_{x \leq t} h(x) \, dt.
\]

Lemma 2.5. Let \( H \) be an \((\alpha, c, D, \nu, \delta)\)-family and \( j \in \mathbb{N}_0 \). Then there exists a positive number \( \eta \) such that for all \( h \in H \) and suitable real polynomials \( q_{h,j} \) one has
\[
I_{h,j}(X) = q_{h,j}(\log X) + O(X^{-\eta}).
\]

It would be possible to compute the degree and the leading coefficient of \( q_{h,j} \), but this will not be relevant later.

Proof. For \( k = 1 \), we may rewrite (I) in the form
\[
\sum_{x \leq t} h(x) = c_h t^\alpha + E(t)
\]
where \( E(t) = E_h(t) \) is piecewise continuous and satisfies \( E(t) \ll t^{\alpha-\delta} \). Hence, by straightforward estimates, one finds that
\[
\int_1^X \frac{(\log(t))^j}{t^{\alpha+1}} \sum_{x \leq t} h(x) \, dt = \frac{c_h}{j+1} (\log X)^{j+1} + D_{h,j} + O(X^{-\delta}(\log X)^j)
\]
in which the real number \( D_{h,j} \) is given by the convergent integral
\[
D_{h,j} = \int_1^\infty E(t) t^{-\alpha-1}(\log t)^j \, dt.
\]
This confirms the assertion of the lemma when \( k = 1 \). More precisely, in this case, any \( 0 < \eta < \delta \) is admissible.

We proceed by induction and suppose that \( k > 1 \), and that the lemma has been established for all smaller values of \( k \). We split the set \( \Delta^{(k)} \) into \( k \) disjoint subsets. To describe this dissection, put \( t_0 = 1 \) and
\[
(2.9) \quad \beta = \min(\nu, \delta(2D+4k)^{-1}).
\]
For \( 0 \leq l < k \), let
\[
\Delta^{(k,l)} = \{ t \in \Delta^{(k)} : t_l > t_{l+1}^{\beta} \ (l < i < k), \ t_l \leq t_{l+1}^{\beta} \}
\]
and write \( \Delta^{(k,l)}(X) = \Delta^{(k,l)} \cap \Delta^{(k)}(X) \). Then indeed \( \Delta^{(k,l)}(X) \) is the disjoint union of \( \Delta^{(k,l)}(X) \) with \( 0 \leq l < k \), so that we now have
\[
(2.10) \quad I_{h,j}(X) = \sum_{l=0}^{k-1} I_{h,j,l}(X)
\]
confirm that for \( Z \) exists, and that this differs from the same integral over \( \Delta^{(k,0)} \) by \( O(X^{-\delta \beta^k}) \). Consequently, by (2.11) and (2.12),

(2.13) \[ I_{h,j,0}(X) = c_h \int_{\Delta^{(k,0)}(X)} \frac{(\log(t))^j}{t^{\alpha+1}} \sum_{x \leq t} h(x) \, dt + D_{h,j,0} + O(X^{-\delta \beta^k}). \]

At this point, we interrupt the treatment of \( I_{h,j,0}(X) \) and turn to \( I_{h,j,l}(X) \) with \( 1 \leq l < k \). For \( t \in \mathbb{R}^k \), write \( t = (t', t'') \) with \( t' = (t_1, \ldots, t_l) \) and \( t'' = (t_{l+1}, \ldots, t_k) \). By (2.10), one has \( \|t'\| \leq \|t''\|^\nu \) for all \( t \in \Delta^{(k,l)} \). Hence, by (II), the function \( E_{h,l}(x', t'') \) defined through the equation

(2.14) \[ \sum_{x'' \leq t''} h(x', x'') = c_{h,l}(x') \langle t'' \rangle^\alpha + E_{h,l}(x', t'') \]

satisfies the bound \( E_{h,l}(x', t'') \ll \langle t'' \rangle^\alpha t_{l+1}^{-\delta} |x'|^D \) uniformly in \( x' \leq t' \). The strategy is now the same as in the treatment of \( I_{h,j,0}(X) \). We shall sum (2.14) over \( x' \leq t' \) and insert the result into (2.11). With this end in view, put

\[ R_l(t) = \sum_{x' \leq t'} E_{h,l}(x', t''). \]

This defines a function on \( \Delta^{(k,l)} \) satisfying \( R_l(t) \ll \langle t' \rangle \langle t'' \rangle^{\alpha} t_{l+1}^{-\delta} t_i^D \). For \( Z \geq 1 \) we now see that

(2.15) \[ \int_{\Delta^{(k,l)}(2Z) \setminus \Delta^{(k,l)}(Z)} \frac{(\log(t))^j}{t^{\alpha+1}} |R_l(t)| \, dt \ll \int_{\mathcal{R}_l(Z)} (t'')^{-\delta} t_{l+1}^{-\delta} \int_{\Delta^{(l)}(t_i^D)} \langle t' \rangle^{\alpha} t_i^D \, dt' \, dt'' \]

where \( \mathcal{R}_l(Z) = \{ t'' : Z < t_k \leq 2Z, t_{i+1}^D \leq t_i \leq t_{i+1} (l < i < k) \} \).
We bound the inner integral by brute force. First one notes that \((t')^{-\alpha} \leq 1\), and consequently that \((t')^{-\alpha} t^\beta \leq t^\beta_{l+1}\) holds for all \(t' \in \Delta(l)(t^\beta_{l+1})\). Then, since the measure of \(\Delta(l)(t^\beta_{l+1})\) does not exceed \(t^\beta_{l+1}\), we find that the inner integral in (2.16) is bounded above by \(t^D l^\beta\), irrespective of the actual value of \(l\). By (2.9), we have \((D + \beta) < \frac{1}{2} \delta\). Hence, by (2.15),
\[
\int_{\Delta(k,l)(Z)} \frac{(\log(t))^{j}}{(t)^{a+1}} |R_t(t)| \, dt \ll \int_{\Delta(l)(Z)} (t'')^{-1/2} \, dt'' \ll Z^{-\delta/2}.
\]

Much as before, on summing over dyadic ranges, it follows that the integral
\[
D_{h,j,l} = \int_{\Delta(k,l)} \frac{(\log(t))^{j}}{(t)^{a+1}} R_t(t) \, dt
\]
exists and differs from the same integral over \(\Delta(k,l)(X)\) by \(O(X^{-\delta/2})\). By (2.14) and (2.11), we infer that
\[
I_{h,j,l}(X) = \int_{\Delta(k,l)(X)} \frac{(\log(t))^{j}}{(t)^{a+1}} \sum_{x^l \leq t'} c_{h,j,l}(x') \, dt + D_{h,j,l} + O(X^{-\delta/2}).
\]

Let \(K_{h,j,l}(X)\) denote the integral on the right hand side of the previous display. Since \(\log(t) = \log(t') + \log(t'')\), binomial expansion shows that
\[
K_{h,j,l}(X) = \sum_{r=0}^{j} \binom{j}{r} \int_{\mathcal{J}_l(X)} \frac{(\log(t''))^{j-r}}{(t'')} \int_{\Delta(l)(t^\beta_{l+1})} \frac{(\log(t'))^r}{(t')^{a+1}} \sum_{x^l \leq t'} c_{h,j,l}(x') \, dt' \, dt''
\]
in which
\[
\mathcal{J}_l(X) = \{t^l : t_k \leq X, t^\beta_{l+1} \leq t_i \leq t_{i+1} (l < i < k)\}.
\]

To compute the inner integral in (2.17), we apply the induction hypothesis together with Lemma 2.3. It then follows that this integral equals \(Q_{h,l,r}(\log t^\beta_{l+1}) + P_{h,l,r}(t^\beta_{l+1})\), with a suitable real polynomial \(Q_{h,l,r}\) and a suitable function \(P_{h,l,r}\) satisfying the estimate \(P_{h,l,r}(t) \ll (-\eta(l))\). Here, \(\eta(l)\) is the positive number that the induction hypothesis produces for the family \(c_{h,l}\). An argument similar to the one used around (2.15) and leading to (2.16) now shows that for there is a real number \(E_{h,j,l,r}\) such that
\[
\int_{\mathcal{J}_l(X)} \frac{(\log(t''))^{j-r}}{(t'')} F_{h,l,r}(t^\beta_{l+1}) \, dt'' = E_{h,j,l,r} + O(X^{-\eta(l)})\beta^{\alpha}/2).
\]

From (2.17) we now deduce that there is a real number, say \(E_{h,j,l}\), such that
\[
K_{h,j,l}(X) = E_{h,j,l} + \int_{\mathcal{J}_l(X)} \sum_{r=0}^{j} \binom{j}{r} \frac{(\log(t''))^{j-r}}{(t'')} Q_{h,l,r}(\log t^\beta_{l+1}) \, dt'' + O(X^{-\eta(l)})\beta^{\alpha}/2).
\]

Hence, whenever \(0 < \eta < \frac{1}{2} \beta k \min(\eta(l), \delta)\), the formula (2.16) yields
\[
I_{h,j,l}(X) = E_{h,j,l} + \int_{\mathcal{J}_l(X)} \sum_{r=0}^{j} \binom{j}{r} \frac{(\log(t''))^{j-r}}{(t'')} Q_{h,l,r}(\log t^\beta_{l+1}) \, dt'' + O(X^{-\eta(l)}).
\]

To compute the remaining integral here, one expands \(Q_{h,l,r}(\log t^\beta_{l+1})(\log(t''))^{j-r}\) as a polynomial in \(\log t_i, l < i \leq k\). We may then rewrite this integral as a linear combination
of integrals of the type
\[
\int_{S_k(X)} \frac{(\log t_k)^{b_k} \cdots (\log t_{l+1})^{b_{l+1}}}{t_k \cdots t_{l+1}} \, dt''
\]
\[
= \int_{1}^{X} \int_{t_k}^{t_k} \cdots \int_{t_{l+2}}^{t_{l+2}} \frac{(\log t_k)^{b_k} \cdots (\log t_{l+1})^{b_{l+1}}}{t_k \cdots t_{l+1}} \, dt_l \cdots dt_k
\]
with \(b_{l+1}, \ldots, b_k \in \mathbb{N}_0\). These integrals can be computed explicitly, and are polynomials in \(\log X\). Similarly, the integral in (2.13) is a polynomial in \(\log X\). This shows that all \(I_{h,j}(X)\) are polynomials in \(\log X\), up to an error not exceeding \(O(X^{-\eta})\). By (2.10), the same is then true for \(I_{h,j}(X)\), completing the induction.

**Lemma 2.6.** Let \(\mathcal{H}\) be an \((\alpha, c, D, \nu, \delta)\)-family and \(j \in \mathbb{N}_0\). Then there exists a positive number \(\eta\) such that for all \(h \in \mathcal{H}\) and suitable real polynomials \(Q_{h,j}\) one has
\[
\int_{[1,X]^k} \frac{(\log t)^{j}}{(t)^{\alpha+1}} \sum_{x \leq t} h(x) \, dt = Q_{h,j}(\log X) + O(X^{-\eta}).
\]

For a proof, we only need to observe that for any \(t \in [1,X]^k\) satisfying \(t_i \neq t_l\) for all \(i \neq l\) there is a unique \(\sigma \in S_k\) such that \(^\sigma t \in \Delta^k(X)\). Since the set of all \(t \in \mathbb{R}^k\) where at least two coordinates are equal is a set of measure 0, we may conclude that
\[
\int_{[1,X]^k} \frac{(\log t)^{j}}{(t)^{\alpha+1}} \sum_{x \leq t} h(x) \, dt = \sum_{\sigma \in S_k} I_{\sigma,j}(X),
\]
and the lemma follows from Lemma 2.5.

### 2.4. A mean value estimate.

Our next result is a light-weight version of Theorem 2.1. It features the real number
\[
V_{k,j} = \int_{[0,1]^k} (\xi_1 + \ldots + \xi_k)^j \, d\xi,
\]
defined whenever \(k \in \mathbb{N}, j \in \mathbb{N}_0\). One may calculate this integral elementarily to obtain the alternative expression
\[
(2.18) \quad V_{k,j} = \sum_{a_1 + \ldots + a_k = j} \binom{j}{a_1 a_2 \ldots a_k} \frac{1}{(a_1 + 1) \cdots (a_k + 1)}
\]
where the variables \(a_i\) run over non-negative integers.

**Theorem 2.7.** Let \(\mathcal{H}\) be an \((\alpha, c, D, \nu, \delta)\)-family and \(j \in \mathbb{N}_0\). Then there exists a positive number \(\eta\) such that for all \(h \in \mathcal{H}\) and suitable real polynomials \(p_{h,j}\) of degree at most \(k + j\) one has
\[
(2.19) \quad \sum_{x_j \leq X} \frac{(\log x)^{j}}{(x)^{\alpha}} h(x) = p_{h,j}(\log X) + O(X^{-\eta}).
\]
If \(c_k \neq 0\), the degree of \(p_{h,j}\) is \(k + j\), and its leading coefficient is \(\alpha^k c_k V_{k,j}\).

**Proof.** First observe that
\[
\frac{\partial}{\partial x} (xy)^{\alpha} = \frac{-\alpha q_j(\log(xy))}{x^{\alpha+1} y^\alpha}
\]
where \(q_j(\log(xy))\) is a suitable polynomial.
where \( q_j(t) = t^j + j \alpha^{-1} t^{j-1} \) is a monic polynomial of degree \( j \). Repeated use of this identity and partial summation applied to the \( k \) sums over \( x \) produce the identity

\[
(2.20) \quad \sum_{\substack{x_i \leq X \\ 1 \leq i \leq k}} \frac{(\log(x))^j}{\langle x \rangle^\alpha} h(x) = \sum_{\mathcal{N} \subseteq \{1, \ldots, k\}} \alpha^n \Xi_{\mathcal{N}}
\]

where \( n = \# \mathcal{N} \), where

\[
\Xi_{\emptyset} = (k \log X)^j X^{-\alpha k} \sum_{\substack{x_i \leq X \\ 1 \leq i \leq k}} h(x),
\]

and when \( \mathcal{N} \) is a nonempty subset of \( \{1, \ldots, k\} \).

The strategy is now to prove that for any subset \( \mathcal{N} \) of \( \{1, \ldots, k\} \) there is a polynomial \( p_{\mathcal{N}} = p_{N, \mathcal{V}} \) with the property that

\[
(2.22) \quad \Xi_{\mathcal{N}} = p_{\mathcal{N}}(\log X) + O(X^{-\eta}).
\]

Once this is established, it follows from (2.20) that the asymptotic relation (2.19) holds with some polynomial \( p_{\mathcal{N}} \). The degree and leading coefficient can then be computed by the following trick: for \( \mathcal{N} = \{1, \ldots, k\} \), one may use (I) in the definition of \( \Xi_{\mathcal{N}} \) to deduce that

\[
\Xi_{\mathcal{N}} = c_h \int_{[1,X]^k} \frac{q_{\mathcal{N}}(\log(t))^j}{\langle t \rangle} \frac{1}{t_1 \cdots t_k} \frac{(\log(t))^j}{\langle t \rangle} dt + O((\log X)^{k+j-1}).
\]

Since \( q_{\mathcal{N}} \) is monic of degree \( j \), it follows that

\[
\Xi_{\mathcal{N}} = c_h \int_{[1,X]^k} \frac{(\log(t))^j}{\langle t \rangle} \frac{1}{t_1 \cdots t_k} \frac{(\log(t))^j}{\langle t \rangle} dt + O((\log X)^{k+j-1}).
\]

One may expand the logarithm, using the multinomial theorem. Then, an elementary calculation yields

\[
\Xi_{\mathcal{N}} = c_h \sum_{a_1 + \cdots + a_k = j} \binom{j}{a_1 a_2 \cdots a_k} \int_{[1,X]^k} \frac{(\log(t_1)^{a_1} \cdots (\log(t_k)^{a_k})}{t_1 \cdots t_k} dt + O((\log X)^{k+j-1})
\]

Similarly, but using (I) only as an upper bound, it is immediate that \( \Xi_{\mathcal{N}} \leq (\log X)^{n+j} \) holds for all subsets \( \mathcal{N} \) of \( \{1, \ldots, k\} \). Hence, by (2.20) and (2.18), the sum on the left hand side of (2.19) equals \( \alpha^k V_{k,j} c_h (\log X)^{k+j} + O((\log X)^{k+j-1}) \). This is compatible with (2.19) only when \( p_{h,j} \) has degree at most \( k + j \), and for \( c_h \neq 0 \), the degree must be \( k + j \) with leading coefficient \( \alpha^k V_{k,j} c_h \), as required to complete the proof of Theorem 2.7.

There remains the task to confirm (2.22). Two cases are easy. For \( \mathcal{N} = \{1, \ldots, k\} \), the desired expansion for \( \Xi_{\mathcal{N}} \) follows from Lemma 2.6. Also, by (I) and the definition of \( \Xi_{\emptyset} \), one finds that

\[
\Xi_{\emptyset} = (k \log X)^j (c_h + O(X^{-\delta}))
\]

confirming (2.22) in the case where \( \mathcal{N} = \emptyset \).
This leaves the cases where $1 \leq n \leq k - 1$. For these $n$ we write $\Xi_n = \Xi_{(1, \ldots, n)}$. Let $t = (t_1, \ldots, t_n)$. By multinomial expansion, there are certain constants $\gamma_{r,s} \in \mathbb{R}$ such that
\[
q_{(1, \ldots, n)}(\log((t)X^m)) = \sum_{r+s \leq j} \gamma_{r,s}(\log(t))^r(\log X)^s,
\]
and consequently, one may rewrite the defining equation (2.21) for $\Xi_n$ as
\[
(2.23) \quad \Xi_n = X^{-\alpha m} \sum_{r+s \leq j} \gamma_{r,s}(\log X)^s \int_{[1,X]^n} \frac{(\log(t))^r}{(t)^{\alpha+1}} \sum_{x_1 \leq t_i, 1 \leq i \leq n} \sum_{x_i \leq X} h(x) \, dt.
\]

The asymptotic evaluation of $\Xi_n$ is performed in a manner similar to the proof of Lemma 2.5. However, the details are somewhat different because the two innermost sums in (2.23) are both nonempty, so that there is at least one "long" sum $x_k \leq X$ involved. The partition of the set $\Delta^{(n)}(X)$ in the argument below will therefore be different from the arrangement in the proof of Lemma 2.5.

The first step is to sort the $t_i$ by size. This can be done by the argument used to prove Lemma 2.6. Indeed, when $\sigma \in S_n$, we define $\sigma' \in S_k$ by $\sigma'(i) = \sigma(i)$, for $1 \leq i \leq n$, and $\sigma'(i) = i$ for $n < i \leq k$. Then, as in the proof of Lemma 2.6, (2.24)
\[
\int_{[1,X]^n} \frac{(\log(t))^r}{(t)^{\alpha+1}} \sum_{x_1 \leq t_i, 1 \leq i \leq n} \sum_{x_i \leq X} h(x) \, dt = \sum_{\sigma \in S_n} \int_{\Delta^{(n)}(X)} \frac{(\log(t))^r}{(t)^{\alpha+1}} \sum_{x_1 \leq t_i, 1 \leq i \leq n} \sum_{x_i \leq X} h_{\sigma'}(x) \, dt.
\]

We now construct a dissection of $\Delta^{(n)}(X)$. Let $\beta$ be defined by (2.4), and consider the intervals
\[
\mathcal{I}_i = (X^{\beta_{i+1}}, X^{\beta_i}) \quad (0 \leq i < n), \quad \mathcal{I}_n = [1, X^{\beta_n}].
\]
that provide a partition of $[1, X]$ into $n + 1$ subsets. By the box principle, for any $t \in \Delta^{(n)}(X)$, there is at least one $\mathcal{I}_i$ that contains none of the coordinates of $t$, and the smallest such $i$ is denoted by $i(t)$. Once $i(t)$ is determined, we put $l(t) = 0$ if $t_l > X^{\beta_{i(t)}}$, and otherwise we take $l(t)$ to denote the largest $l$ with $t_l \leq X^{\beta_{i(t)+1}}$. Now put
\[
\Delta_{i,l}^{(n)}(X) = \{ t \in \Delta^{(n)}(X) : i(t) = i, l(t) = l \}.
\]
Note that whenever $i = i(t)$, then all the intervals $\mathcal{I}_0, \ldots, \mathcal{I}_{i-1}$ will contain at least one coordinate of $t$. Hence, $\Delta_{i,l}^{(n)}(X)$ will be nonempty only when $i + l \leq n$, and $\Delta^{(n)}(X)$ is the disjoint union of these sets. We now write
\[
(2.25) \quad J_{r,n,i,l}(h) = X^{-\alpha m} \int_{\Delta_{i,l}^{(n)}(X)} \frac{(\log(t))^r}{(t)^{\alpha+1}} \sum_{x_j \leq t_j, 1 \leq j \leq n} \sum_{x_j \leq X} h(x) \, dt.
\]
Then, by (2.23) and (2.24),
\[
(2.26) \quad \Xi_n = \sum_{\sigma \in S_n} \sum_{r+s \leq j} \gamma_{r,s}(\log X)^s \sum_{i+l \leq n} J_{r,n,i,l}(h_{\sigma}).
\]

We begin with the evaluation of $J_{r,n,i,0}(h)$. Note that $\Delta_{0,0}^{(n)}(X)$ is empty so that we may suppose that $i \geq 1$. Then, for $t \in \Delta_{i,0}^{(n)}(X)$, one has $t_1 \geq X^{\beta_i} \geq X^{\beta_n}$, and (I) delivers
\[
\sum_{x_j \leq t_j, 1 \leq j \leq n} \sum_{x_j \leq X} h(x) = c_h X^{\alpha m}(t)^\alpha + O(X^{\alpha m - \beta_n}(t)^\alpha).
\]
By \((2.20)\) and straightforward estimates,
\[
J_{r,n,i,0}(h) = c_h \int_{\Delta_{n \cdot i}^0(X)} \frac{(\log(t))^r}{(t)} \, dt + O(X^{-\delta \alpha^2/2}). \tag{2.27}
\]

It remains to evaluate the integral on the right hand side here. We claim that there is a polynomial \(T\) depending only on \(n, i, \beta\) and \(r\) such that
\[
\int_{\Delta_{n \cdot i}^0(X)} \frac{(\log(t))^r}{(t)} \, dt = T(\log X). \tag{2.28}
\]

To see this, let \(n = u_1 > u_2 > \ldots > u_i > u_{i+1} = 1\) be a collection of natural numbers, and put \(u = (u_1, \ldots, u_{i+1})\). Let
\[
\Gamma_{i,u} = \{ t \in \Delta^n(X) : t_{\sigma} \in \mathcal{J}_\lambda \text{ for } u_{\lambda+2} < \sigma \leq u_{\lambda+1} (0 \leq \lambda < i) \}.
\]

By construction, \(\Delta_{n \cdot 0}^0(X)\) is the disjoint union of the \(\Gamma_{i,u}\). Hence, by multinomial expansion, the integral in \((2.28)\) equals
\[
\sum_{n = u_1 > u_2 > \ldots > u_i > u_{i+1} = 1} \sum_{a_1 + \ldots + a_n = r} \left( \frac{\log(t_1)^{a_1} \cdots \log(t_n)^{a_n}}{t_1 \cdots t_n} \right) dt.
\]

By definition of \(\Gamma_{i,u}\), this last integral factorises into integrals over \(t_\sigma \in \mathcal{J}_\lambda\) with \(u_{\lambda+2} < \sigma \leq u_{\lambda+1}\) of dimension \(u_{\lambda+1} - u_{\lambda+2}\). A typical such integral takes the shape
\[
\int_{\sum_{v_1, \ldots, v_s \leq Y} (\log v_1)^{b_1} \cdots (\log v_s)^{b_s}} \frac{dt}{v_1 \cdots v_s}
\]
where \(s\) is the dimension, the \(b_\sigma\) are some of the \(a_1, \ldots, a_n\), and \(Y = X^{\delta^\lambda}\) for some \(\lambda < n\). This integral can be computed explicitly, and is then seen to be a polynomial in \(\log Y\), and hence also a polynomial in \(\log X\). Collecting together confirms \((2.28)\).

By \((2.27)\) and \((2.28)\), we see that \(J_{r,n,i,0}(h)\) is a polynomial in \(\log X\), up to an acceptable error \(O(X^{-\delta \alpha^2/2})\). By (III), the same is true for \(J_{r,n,i,0}(h_{\sigma})\).

The next case we consider is \(l = n\). Since \(l + i \leq n\), this forces \(i = 0\), and one readily checks from the relevant definitions that \(\Delta_{n \cdot 0}^n(X) = \Delta^n(X^\beta)\). Recall that \(\beta \leq \nu\). Hence, on writing \(x' = (x_1, \ldots, x_l)\), we deduce from (II) that
\[
\sum_{\substack{x_j \leq X \\text{for } n < j \leq k}} h(x) = c_{h,l}(x') X^{\alpha m} + O(X^{\alpha m - \delta} |x'|^D).
\]

For \(t \in \Delta^n(X^\beta)\) we may sum over \(x' \leq t'\) to infer that
\[
\sum_{\substack{x_j \leq t_j \\text{for } 1 \leq j \leq n \\text{and } n < j \leq k}} h(x) = X^{\alpha m} \sum_{x' \leq t} c_{h,l}(x') + O(X^{\alpha m - \delta} |t|^n + D).
\]

This may be injected into \((2.25)\). Then, recalling that \(\beta \leq \delta/(4n + 2D)\), one concludes that
\[
J_{r,n,0,0}(h) = \int_{\Delta_{n \cdot 0}^0(X^\beta)} \frac{(\log(t))^r}{(t)^{\alpha+1}} \sum_{x' \leq t} c_{h,l}(x') \, dt + O(X^{-\delta/2}).
\]

By Lemma \(2.3\) we may apply Lemma \(2.3\) with \(c_{h,l}\) in place of \(h\) to evaluate the integral on the right hand side here. It follows that \(J_{r,n,0,0}(h)\) is equal to a polynomial in \(\log X\), up to an error not exceeding \(O(X^{-\eta})\), for some suitable \(\eta > 0\).
We are left with the cases where $1 \leq l < n$. Write $t = (t', t'')$ with $t' = (t_1, \ldots, t_l)$ and $t'' = (t_{l+1}, \ldots, t_n)$. Another inspection of the relevant definitions shows that $t \in \Delta^{(n)}_{\nu}(X)$ holds if and only if $t' \in \Delta^{(l)}(X^{\beta l+1})$ and $t'' \in \Delta^{(n-l)}_{\nu}(X)$. Moreover, since $\beta \leq \nu$, one may use (II) to confirm that whenever $t \in \Delta^{(n)}_{\nu}(X)$, then

$$
\sum_{x_j \leq t_j} \sum_{x_i \leq X} h(x) = c_{h,l}(x') (t'')^{\alpha} X^{\alpha m} + O(X^{\alpha m} (t'')^{\alpha} t_l^{-\delta} |x'|^D).
$$

We sum over $x' \leq t'$ and recall that $t_{l+1} \geq X^{\beta l}$. This produces

$$
\sum_{x_j \leq t_j} \sum_{x_i \leq X, 1 \leq j \leq n, n < j \leq k} h(x) = X^{\alpha m} (t'')^{\alpha} \sum_{x' \leq t'} c_{h,l}(x') + O(X^{\alpha m - \beta l} (t'')^{\alpha} t'|^{n+D}).
$$

Now multiply with $(t)^{-\alpha-1} (\log(t))^{r}$ and integrate over $\Delta^{(n)}_{\nu}(X)$. The error term above then becomes

$$
X^{\alpha m - \beta l} (\log X)^{r} \int_{\Delta^{(n)}_{\nu}(X)} (t)^{-1} |t'|^{n+D} dt \ll X^{\alpha m - \beta l} (\log X)^{r+n} \int_{\Delta^{(l)}(X^{\beta l+1})} |t'|^{n+D} \, dt' \ll X^{\alpha m - \beta l n/2}.
$$

In the last inequality, we have used again that $\beta \leq \delta/(4n + 2D)$. We insert the results into (2.25) and apply the binomial theorem to conclude that, up to an error $O(X^{-\beta l n/2})$, the expression $J_{r,n,i,l}(h)$ equals

$$
\sum_{r' + r'' = r} \binom{r}{r'} \int_{\Delta^{(n-1)}_{\nu}(X)} \frac{(\log(t''))^{r'}}{(t'')^{r'}} \int_{\Delta^{(l)}(X^{\beta l+1})} \frac{(\log(t'))^{r''}}{(t'')^{r''}} \sum_{x' \leq t'} c_{h,l}(x') \, dt'.
$$

By (2.28), the first integral is a polynomial in $\log X$. The second integral coincides with a suitable polynomial in $\log X$, up to an error not exceeding $O(X^{-n})$ for some suitable number $\eta > 0$. This follows once again from Lemma 2.3 and Lemma 2.5.

To sum up the above deliberations, we have now shown that $J_{r,n,i,l}(h)$ equals a suitable polynomial in $\log X$, up to an error not exceeding $O(X^{-\eta})$ for some suitable number $\eta > 0$, for all relevant parameters $r, n, i, l$. By (III), the same is true for $J_{r,n,i,l}(h_{\sigma})$, and (2.22) for $\mathcal{N} = \{1, \ldots, n\}$ now follows from (2.20). By (III) again, this confirms (2.22) for all $\mathcal{N}$. The proof of Theorem 2.7 is complete.

2.5. Away from the spikes. In this section, we discuss the contribution to the sum (2.1) where all the variables $u_j$ are rather large. More precisely, we choose a threshold $W \in [1, N]^k$ and consider

$$
\Upsilon(N, W) = \sum_{w_1, w_2, \ldots, w_k \leq N, w > W} h(w).
$$

When all entries of $W$ are reasonably large, the variables of summation stay away from the spiky part of the hyperbolic constraint $w \leq N$, so that one would hope to handle this sum based on the condition (I) alone. This is indeed the case. The asymptotic formula features the polynomial

$$
p_k(t) = \sum_{l=0}^{k-1} (-1)^{k+l+1} \frac{t^l}{l!}.
$$
Lemma 2.8. Let $\mathcal{H}$ be a set of functions $h : \mathbb{N}^k \to [0, \infty)$ that satisfies the condition (I) with respect to $(\alpha, c, \delta)$, and suppose that the threshold satisfies $\langle W \rangle \leq N^{1/2}$ and $\min W_j \geq (\log N)^{2k/3}$. Then

$$
\Upsilon(N, W) = c_k N^\alpha p_k \left( \alpha \log \frac{N}{\langle W \rangle} \right) + O(N^\alpha (\min W_j)^{-\delta/(2k)}(\log N)^k).
$$

The proof depends on the following combinatorial identity.

Lemma 2.9. Let $k$ and $J$ be natural numbers. Then for $t \in \mathbb{C}$ one has

$$
(1-t)^k \sum_{j_1 + \ldots + j_k \leq J, j_r \geq 0} t^{j_1 + \ldots + j_k} = 1 - t^{J+1} \sum_{l=0}^{k-1} \binom{J+l}{l}(1-t)^l.
$$

When $k = 1$, the claim in Lemma 2.9 is the familiar evaluation of the geometric sum. We proceed by induction and suppose that the formula is known for $k-1$ in place of $k$. Then the left hand side of (2.31) equals

$$(1-t)^k \sum_{j=0}^{J} t^j \sum_{j_1 + \ldots + j_k-1 \leq J-j} t^{j_1 + \ldots + j_k-1}$$

$$= (1-t) \sum_{j=0}^{J} t^j (1-t^{J+1-j} \sum_{l=0}^{k-2} \binom{J+l-j}{l}(1-t)^l).$$

Now replace $l+1$ by $l$ in the inner sum. The above then becomes

$$1 - t^{J+1} - t^{J+1} \sum_{j=0}^{J} \sum_{l=1}^{k-1} \binom{J+l-1-j}{l-1}(1-t)^l.$$

However,

$$\sum_{j=0}^{J} \binom{J+l-1-j}{l-1} = \sum_{j=0}^{J} \binom{l-1+j}{l} = \binom{J+l}{l},$$

as one may verify by induction on $J$. Now (2.31) follows from (2.32).

Proof of Lemma 2.8. We begin with an enveloping argument to reduce the evaluation of $\Upsilon(N, W)$ to box sums of the type

$$\Upsilon(U^+, U^-) = \sum_{U^- < u \leq U^+} h(u).$$

Let $\Theta$ be a real number, $J$ be a natural number, and suppose that $1 < \Theta < 3$ and $\Theta^J = N/\langle W \rangle$. We shall optimize $J$ later, but already note that permissible values of $J$ satisfy $J \gg \log N$. For $j \geq 0$, let $U_{r,j} = W_r \Theta^j$, and define

$$U_j = (U_{1,j_1}, \ldots, U_{k,j_k}).$$

Let $1 = (1,1,\ldots,1)$. We consider boxes $U_j < u \leq U_{j+1}$. This box lies inside the range of summation $u_1 \cdots u_k \leq N$ in (2.29) whenever $U_{1,j_1+1} \cdots U_{k,j_k+1} \leq N$ which in turn holds if and only if $|j|_1 \leq J - k$. Here, and later in this proof, we write

$$|j|_1 = j_1 + \ldots + j_k.$$

In the opposite direction, let $u$ be a point with $u > W$ and $u_1 \cdots u_k \leq N$. Then, there is a unique $j \in \mathbb{N}_0^k$ with $U_j < u \leq U_{j+1}$. The inequalities

$$U_{1,j_1} \cdots U_{k,j_k} < u_1 \cdots u_k \leq N$$

imply $|j|_1 \leq J$. By (2.29) and (2.33), these considerations show that
\begin{equation}
\sum_{|j|_1 \leq J-k} H(U_{j+1}, U_j) \leq \Upsilon(N, W) \leq \sum_{|j|_1 \leq J} H(U_{j+1}, U_j).
\end{equation}
By the inclusion-exclusion principle, the sum $H(U^+, U^-)$ can be expressed in terms of the sum $H(X)$ that was defined in (2.22). In the special case needed here, this strategy gives the identity
\[ H(U_{j+1}, U_j) = \sum_{s \in \{0,1\}^k} (-1)^{k-|s|_1} H(U_{j+s}) \]
whence by (I), it now follows that
\[ H(U_{j+s}) = c_h \langle W \rangle^\alpha e^{\alpha |j+s|_1} + O(\langle W \rangle^\alpha (\min W_j)^{-\delta} \Theta^{|j|_1}) \]
Now put
\[ J^+ = J, \quad J^- = J-k \]
and study the sums
\[ \Upsilon^\pm = \sum_{|j|_1 \leq J^\pm} H(U_{j+1}, U_j) \]
that occur in the sandwich inequalities (2.34). Combining the preceding displays yields
\[ \Upsilon^\pm = c_h \langle W \rangle^\alpha \sum_{|j|_1 \leq J^\pm} \sum_{s \in \{0,1\}^k} (-1)^{k-|s|_1} \Theta^{|j+s|_1} + O(\langle W \rangle^\alpha (\min W_j)^{-\delta} \sum_{|j|_1 \leq J^\pm} \Theta^{|j|_1}) \]
The obvious identity
\[ \sum_{s \in \{0,1\}^k} (-1)^{k-|s|_1} T^{|s|_1} = (T-1)^k \]
allows us to rewrite this as
\[ \Upsilon^\pm = c_h (\Theta^\alpha - 1)^k \langle W \rangle^\alpha \sum_{|j|_1 \leq J^\pm} \Theta^{|j|_1} + O(\langle W \rangle^\alpha (\min W_j)^{-\delta} \sum_{|j|_1 \leq J^\pm} \Theta^{|j|_1}) \]
It will now be convenient to define $r$ by $\min W_j = W_r$. Then, the error term above does not exceed
\[ \langle W \rangle^\alpha W_r^{-\delta} \Theta^{|j|_1 \leq J} \ll N^\alpha W_r^{-\delta} J^k. \]
To compute the leading term, we multiply (2.31) with $(-1)^k$ and choose $t = \Theta^\alpha$. Then $t^{J^+} = N^\alpha \langle W \rangle^{-\alpha}$, and one finds that
\begin{equation}
\Upsilon^+ = c_h N^\alpha \Theta^\alpha \sum_{l=0}^{k-1} \binom{J+l}{l} (-1)^{k+1+l} (\Theta^\alpha - 1)^l + O(\langle W \rangle^\alpha + N^\alpha W_r^{-\delta} J^k).
\end{equation}
The same argument also gives
\begin{equation}
\Upsilon^- = c_h N^\alpha \Theta^\alpha (1-k) \sum_{l=0}^{k-1} \binom{J-k+l}{l} (-1)^{k+1+l} (\Theta^\alpha - 1)^l + O(\langle W \rangle^\alpha + N^\alpha W_r^{-\delta} J^k).
\end{equation}
We now choose $J = \lfloor W_r^{\delta/(2k)} \rfloor$ so that $J \geq \log N$ and $1 < \Theta \leq e$, as required. We then have
\[ \Theta = \exp \left( J^{-1} \log \frac{N}{\langle W \rangle} \right) = 1 + J^{-1} \log \frac{N}{\langle W \rangle} + O(J^{-2} (\log N)^2). \]
Binomial expansion gives
\begin{equation}
\Theta^\alpha = 1 + \alpha J^{-1} \log \frac{N}{\langle W \rangle} + O(J^{-2} (\log N)^2). \end{equation}
One also has

\[
\binom{J+l}{l} = \frac{J^l}{l!} + O(J^{l-1})
\]

so that

\[
\binom{J+l}{l}(\Theta^\alpha - 1)^l = \frac{\alpha^l}{l!} \left( \log \frac{N}{\langle W \rangle} \right) + O(J^{-1}(\log N)^{l+1}).
\]

We multiply with \((-1)^{k+l+1}\) and sum over \(l\). Recalling the notation introduced in (2.30), we then infer from (2.35), (2.37) and the preceding display that

\[
(2.38) \quad Y^+ = c_h N^\alpha p_k \left( \alpha \log \frac{N}{\langle W \rangle} \right) + O(N^\alpha (\log N)^k J^{-1} + \langle W \rangle^\alpha + N^\alpha W^{-\delta} J^k).
\]

A simple cosmetical change in this argument, now starting from (2.36) provides the same asymptotic formula for \(Y^-\). Consequently, by (2.34), this formula also holds for \(Y(N, W)\). Our choice for \(J\) then yields the assertion of Lemma 2.8.

2.6. The endgame. We are ready to assemble the puzzle. The contribution to the sum (2.11) resulting from summands \(h(x)\) where all coordinates \(x_j\) are “large” can be evaluated by Lemma 2.8. The contribution from terms where all \(x_j\) are “small” will not be of significance, for obvious reasons. This leaves summands where \(x\) has small and large coordinates simultaneously. Here the strategy is to sum over the large coordinates with the aid of Lemma 2.8, and then sum the result over the small coordinates by an appeal to Theorem 2.7. This is successful only if there is a huge gap between the small and the large coordinates. One can always find such a gap, but its position will depend on \(x\). Hence, we will follow a strategy that is largely similar to the one used in the proof of Theorem 2.7, but there are additional combinatorial complications because summands which have at least two equal coordinates in the vector \(x\) affect the lower order terms in \(P_h\).

Fix an \((\alpha, c, D, \nu, \delta)\)-family \(\mathcal{H}\) and \(k \geq 2\). The set \(\mathcal{H}\) remains such a family if the values of \(\nu\) and \(\delta\) shrink, and we may therefore suppose that

\[
\nu \leq 1/(2k), \quad \delta \leq 1/2.
\]

Also, as in Lemma 2.4, put \(A = D + (k + 1)\alpha + \nu^{-1}(1 + \alpha)\) and then define

\[
(2.39) \quad B = 4Ak^2/\delta.
\]

Fix a parameter \(V \geq 4\), and suppose that \(N\) is sufficiently large for \(V^{B_k} \leq N^\nu\) to hold. Then use the sequence

\[
V_0 = 1, \quad V_1 = V, \quad V_j = V_{j-1}^B (2 \leq j \leq k), \quad V_{k+1} = N
\]

to define the intervals

\[
\mathcal{V}_0 = [V_0, V_1], \quad \mathcal{V}_j = (V_j, V_{j+1}] \quad (1 \leq j \leq k).
\]

Then \([1, N]\) is the disjoint union of the \(k + 1\) sets \(\mathcal{V}_j\). Hence, for \(x \in \mathbb{N}^k\) with \(\langle x \rangle \leq N\) there is at least one \(l \in \{0, \ldots, k\}\) with \(x_j \not\in \mathcal{V}_i\) for all \(1 \leq j \leq k\), and we may define \(l(x)\) as the largest such \(l\). We sort terms in (2.41) according to the value of \(l(x)\). Thus, we write

\[
(2.41) \quad \Upsilon_l(N) = \sum_{\substack{\langle x \rangle \leq N \\{l(x) = l\}}} h(x)
\]

and note that

\[
(2.42) \quad \Upsilon(N) = \Upsilon_0(N) + \Upsilon_1(N) + \ldots + \Upsilon_k(N).
\]
The condition that \( l(x) = k \) is equivalent with \( |x| \leq V_k \), whence by (I) and (2.39) one obtains the crude bound

\[
\Upsilon_k(N) \leq H(V_k, \ldots, V_k) \ll V_k^{k\alpha} \ll N^{\alpha/2}.
\]

In line with the comments preceding the current discussion, in our approach to the estimation of \( \Upsilon_1(N) \) we will treat coordinates \( x_j \) with \( x_j \leq V_i \) as “small”, and all \( x_j > V_{i+1} \) as “large”. To make this precise, let \( 0 \leq l \leq k-1 \) and \( x \in \mathbb{N}^k \) with \( \langle x \rangle \leq N \) and \( l(x) = l \).

With such an \( x \), we associate the sets

\[
\mathcal{J} = \{ j : 1 \leq j \leq k, x_j \leq V_1 \}, \quad \mathcal{L}_m = \{ j : x_j \in \mathcal{V}_m \}.
\]

Then, the maximality of \( l(x) \) implies that \( \mathcal{L}_{i+1}, \ldots, \mathcal{L}_k \) are non-empty, and \( \{1, \ldots, k\} \) is the disjoint union of \( \mathcal{J} \) and \( \mathcal{L}_m, l < m \leq k \).

An ensemble of sets \( \mathfrak{A} = \{ \mathcal{J}, \mathcal{L}_{i+1}, \mathcal{L}_{i+2}, \ldots, \mathcal{L}_k \} \) with all \( \mathcal{L}_m \) non-empty and such that \( \{1, \ldots, k\} \) is the disjoint union of \( \mathcal{J}, \mathcal{L}_i \) \((i < k)\) will be referred to as permissible to the natural number \( l \). For any \( x \in \mathbb{N}^k \) with \( \langle x \rangle \leq N \) and \( l(x) = l \) the sets (2.44) form an ensemble permissible to \( l \) that we denote by \( \mathfrak{A}(x) \).

For an ensemble \( \mathfrak{A} \) that is permissible to some \( l \in \{0, \ldots, k-1\} \), we now define

\[
\Upsilon_{\mathfrak{A}}(N) = \sum_{\langle x \rangle \leq N, \mathfrak{A}(x) = \mathfrak{A}} h(x)
\]

and then have

\[
\Upsilon_l(N) = \sum_{\mathfrak{A}} \Upsilon_{\mathfrak{A}}(N)
\]

where the sum extends over all ensembles \( \mathfrak{A} \) that are permissible to \( l \).

With (2.42) and (2.45) in hand, our initial decomposition of \( \Upsilon(N) \) is now complete.

We proceed to deduce Theorem 2.1 in two steps, each depending on this decomposition yet with a different choice for the parameter \( V \). We begin with a weak form of Theorem 2.1 in which a leading term is already identified.

**Lemma 2.10.** Let \( \mathcal{H} \) be an \((\alpha, c, D, \nu, \delta)\)-family. Then, uniformly for any \( h \in \mathcal{H} \),

\[
\Upsilon(N) = C_h \alpha^{k-1} \frac{V^\alpha (\log N)^{k-1}}{(k-1)!} + O(N^\alpha (\log N)^{k-2} \log \log N).
\]

**Proof.** The case \( k = 1 \) follows from (I). Hence, we may assume that \( k \geq 2 \). We choose

\[
V = (\log N)^B
\]

with \( B \) as in (2.39) and decompose \( \Upsilon(N) \) according to (2.42) and (2.45). By (2.43), the summand \( \Upsilon_k(N) \) is absorbed into the error term in (2.46). Next, consider the ensemble \( \mathfrak{A} = \{0, \{1,2, \ldots, k\}\} \) that is permissible to \( k-1 \), and note that \( \Upsilon_{\mathfrak{A}}(N) = \Upsilon(N,(V_k, \ldots, V_k)) \), in the notation introduced in (2.29). We have \( V_k = (\log N)^{Bk} \) so that Lemma 2.8 yields

\[
\Upsilon(N,(V_k, \ldots, V_k)) = C_h N^\alpha p_k(\alpha \log NV_k^{-k}) + O(N^\alpha)
\]

\[
= C_h N^\alpha \frac{\alpha^{k-1}}{(k-1)!} (\log N)^{k-1} + O(N^\alpha (\log N)^{k-2} \log \log N).
\]

Here the final line corresponds to the right hand side of (2.46). To complete the proof of Lemma 2.10 it remains to show that for any other ensemble \( \mathfrak{A} \) that is permissible to some \( l \) the sum \( \Upsilon_{\mathfrak{A}}(N) \) can be absorbed into the error term in (2.46).
First consider ensembles in which the set \( J \) is empty. Thus suppose that \( A = \{0, L_1, \ldots, L_k\} \) is permissible to \( l \). The case \( l = k \) is discussed in \((2.48)\) so that we are reduced to the range \( 0 \leq l \leq k - 2 \). Since \( L_{l+1} \) is non-empty, at least one of the \( x_j \) is contrained to \( V_{l+1} \), and we temporarily suppose that this is so for \( x_1 \). Any other coordinate \( x_j \) of an \( x \) with \( A(x) = A \) must obey the inequality \( x_j \geq V_{l+1} \), and consequently, one has the crude upper bound

\[
\Upsilon_A(N) \leq \sum_{V_{l+1} < x_1 \leq V_{l+2}} \sum_{x_j > V_{l+1}} h(x) \sum_{0 \leq j \leq k} \langle x \rangle \leq N
\]

Recall that \( 0 \leq l \leq k - 2 \) so that \( V_1 \leq V_{l+1} < V_{l+2} \leq V_k \). Lemma \(2.8\) now delivers the bound

\[
\Upsilon_A(N) \leq c_h N^\alpha p_k(\alpha \log N V_{l+1}^{-k} - p_k(\alpha \log N V_{l+2}^{-1} V_{l+1}^{-k})) + O(N^\alpha)
\]

which readily implies the desired estimate

\[
\Upsilon_A(N) \ll N^\alpha \left( \log \frac{V_{l+2}}{V_{l+1}} \right) (\log N)^{k-2} \ll N^\alpha (\log N)^{k-2} \log \log N.
\]

By (III), this upper bound remains valid if another index takes the special role of \( j = 1 \) in the above argument. This completes the discussion of ensembles with \( J \neq \emptyset \).

Next, suppose that \( A = \{J, L_1, \ldots, L_k\} \) is an ensemble permissible to \( l \) with \( J \) non-empty. Since all \( L_m \) are also non-empty, this enforces that \( l \geq 1 \). View of (III), we may suppose that \( J = \{1, \ldots, r\} \) with some \( r \geq 1 \). We write \( w = (x_1, \ldots, x_r) \) and \( x = (w, y) \) with \( y_j = x_{r+j} \). For \( x \) with \( A(x) = A \), one has \( y_j > V_{l+1} \) for \( 1 \leq j \leq k - r \) and \( x_j \leq V_l \) for \( 1 \leq j \leq r \). It follows that

\[
\Upsilon_A(N) \leq \sum_{|w| \leq V_l} \sum_{y \leq N/|w|} \sum_{1 \leq j \leq k-r} h(w, y).
\]

We evaluate the inner sum by applying Lemma \(2.8\) to the function \( g_{h, w} \) considered in Lemma \(2.4\). This yields

\[
\sum_{y \leq N/|w|} \sum_{1 \leq j \leq k-r} h(w, y) = c_{h, r}(w) \frac{N^\alpha}{|w|^{\alpha}} p_{k-r} \left( \alpha \log \frac{N V_{l+1}^{-k}}{|w|} \right) + O(N^\alpha V_{l+1}^{-\delta/2k} (\log N)^{k} |w|^A)
\]

\[
\ll c_{h, r}(w) N^\alpha (\log N)^{k-r-1} + N^\alpha V_{l+1}^{-\delta/2k} (\log N)^k |w|^A.
\]

One may now sum over \( w \) with the aid of Theorem \(2.7\) to deduce that

\[
\Upsilon_A \ll N^\alpha (\log N)^{k-r-1} \log V_l^r + N^\alpha V_{l+1}^{(A+1) - \delta/2k} (\log N)^k.
\]

The first term is acceptable by \((2.47)\), and the second is \( O(N^\alpha) \) in view of \((2.39)\). This completes the proof of Lemma \(2.10\).

In the proof of Lemma \(2.10\) it was possible to estimate \( \Upsilon_A(N) \) rather crudely, once the leading term was identified in \((2.48)\). We now build up a related argument to establish Theorem \(2.11\). Let \( B \) be as defined in \((2.39)\) and put \( \kappa = \nu/(kB^k) \). Now take \( V = N^\kappa \) to obtain another decomposition of \( \Upsilon(N) \) via \((2.41)\) and \((2.42)\). We shall show that for an
ensemble $A$ permissible to some $l \in \{0, \ldots, k-1\}$ there is a real polynomial $P_A = P_{A,l}$ of degree at most $k-1$ and such that
\begin{equation}
(2.49) \quad \Upsilon_A(N) = N^\alpha P_A(\log N) + O(N^{\alpha-\eta})
\end{equation}
holds with some suitably small $\eta > 0$. Once this is established, we deduce from (2.41) and (2.45) in conjunction with (2.43) that the asymptotic relation
\begin{equation}
(2.43) \quad \Upsilon(N) = N^\alpha P_\ast(\log N) + O(N^{\alpha-\eta})
\end{equation}
holds with
\begin{equation}
P_\ast = \sum P_{A,l}
\end{equation}
in which the sum extends over all ensembles permissible to some $l \in \{0, \ldots, k-1\}$. Then $P_\ast$ is a polynomial of degree at most $k-1$, but Lemma 2.10 shows that for $c_h > 0$ the degree is indeed $k-1$, and that the leading coefficient is as claimed in Theorem 2.1. Further, when $c_h = 0$, then Lemma 2.10 implies that the degree of $P_\ast$ does not exceed $k-2$. Consequently, the verification of (2.49) will complete the proof of Theorem 2.1.

First consider an ensemble $A = \{0, L_1, \ldots, L_k\}$ that is permissible to $l$. If $l = k-1$ then $L_k = \{1, \ldots, k\}$ and $\Upsilon_A(N) = \Upsilon(N, (V_k, \ldots, V_k))$, as observed in the proof of Lemma 2.8. In contrast with the discussion in (2.48), now $V_k$ is a fixed power of $N$, and Lemma 2.8 delivers the asymptotic relation
\begin{equation}
(2.50) \quad \Upsilon_A(N) = c_h N^\alpha p_k(\alpha \log N V_k^{-k}) + O(N^{\alpha+\varepsilon V_k^{-\delta/2k}}),
\end{equation}
as is required in (2.49). It remains to consider the case where $0 \leq l \leq k-2$. Then the conditions on $x$ in the sum defining $\Upsilon_A(N)$ are $V_m < x_j \leq V_{m+1}$ for $j \in L_m$. For $l < m < k$ we use $(V_m, V_{m+1}) = (V_m, \infty) \setminus (V_{m+1}, \infty)$ and the inclusion-exclusion principle to obtain a representation
\begin{equation}
\Upsilon_A(N) = \sum_{V} (-1)^{\varepsilon(V)} \Upsilon(N, V)
\end{equation}
where $\Upsilon(N, V)$ is given by (2.28), where $V$ runs through the vectors $V = (V^{(1)}, \ldots, V^{(k)})$ with $V^{(j)}$ either $V_m$ or $V_{m+1}$ when $j \in L_m$ with $m < k$, and $V^{(j)} = V_k$ for $j \in L_k$, and where $\varepsilon(V) \in \{0, 1\}$ is chosen appropriately. Since $V_1 = N^\kappa$, it follows from Lemma 2.8 that
\begin{equation}
\Upsilon(N, V) = c_h N^\alpha p_k(\alpha \log N/\langle V \rangle) + O(N^{\alpha-\eta})
\end{equation}
holds for all $V$ under consideration. Since all $V_j$ with $j \geq 1$ are positive powers of $N$, one notes that $\alpha \log N/\langle V \rangle$ is a constant multiple of $\log N$. Thus, any $\Upsilon(N, V)$ in (2.50) satisfies an asymptotic formula of the type desired in (2.40), and so does $\Upsilon_A(N)$. This confirms (2.49) for ensembles in which $\varnothing$ is the empty set.

Now let $A = \{\varnothing, L_{l+1}, \ldots, L_k\}$ be an ensemble permissible to $l \in \{0, \ldots, k-1\}$, and suppose that $\varnothing = \{1, \ldots, r\}$ with $r \geq 1$. As in the proof of Lemma 2.10 put $x = (w, y)$ with $y_j = x_{r+j}$. Then
\begin{equation}
\Upsilon_A(N) = \sum_{|w| \leq V_l} \sum_{y} h(w, y)
\end{equation}
where the sum over $y$ is constrained by $\langle y \rangle \leq N/\langle w \rangle$ and $y_j \in \Upsilon_m$ with some appropriate $m = m(j) \in \{l + 1, \ldots, k\}$. As in the previous argument, for $m(j) < k$, we resolve the
condition $y_j \in \mathcal{V}_m = (V_m, \infty) \setminus (V_{m+1}, \infty)$ by the inclusion-exclusion principle, and rewrite the previous expression as

$$\Upsilon_\eta(N) = \sum_{|w| \leq V_l} \sum_{V} (-1)^{\varepsilon(V)} \sum_{\langle y \rangle \leq N/(w)} h(w, y)$$

where $V = (V^{(1)}, \ldots, V^{(k-r)})$ runs through vectors with $V^{(j)}$ either $V_m$ or $V_{m+1}$ when $j \in \mathcal{L}_m$ with $m < k$, and $V^{(j)} = V_k$ for $j \in \mathcal{L}_k$, and $\varepsilon(V) \in \{0, 1\}$ is chosen appropriately. Note that $V^{(j)} \geq V_l + 1$ for all $j$. Therefore, Lemma 2.8 and Lemma 2.4 yield

$$\sum_{\langle y \rangle \leq N/(w)} h(w, y) = c_{h,r}(w) N^{\alpha} p_{k-r} \left( \alpha \log \frac{N}{\langle w \rangle} \right) + O(N^{\alpha+\varepsilon} V^{-\delta/2k}_{l+1}(w)^A).$$

Now note that $\langle V \rangle = N^\eta$ for some positive $\eta$, and hence that

$$\log \frac{N}{\langle w \rangle \langle V \rangle} = (1 - \eta) \log N - \log \langle w \rangle.$$ 

Consequently, $p_{k-r}(\alpha \log N/(w)\langle V \rangle)$ can be written as a polynomial in $\log \langle w \rangle$, with coefficients containing powers of $\log N$. It is then possible to sum the equation (2.51) over $|w| \leq V_l$ by Theorem 2.7, and the result over the finitely many $V$. Since $\log V_l$ is a constant multiple of $\log N$, one obtains a formula

$$\Upsilon_\eta(N) = N^{\alpha} P_\eta \left( \log N \right) + O(N^{\alpha+\varepsilon} V^{-\delta/2k}_{l+1} V^{r(A+1)}).$$

in which $P_\eta$ is as desired, and an inspection of (2.41) shows that the error term is indeed $O(N^{\alpha-\eta})$. This completes the proof of (2.49) in all cases.

### 3. Weyl sums over products

#### 3.1. Introductory comment.

It is apparent that a circle method approach to count solutions of the equation (1.1) will involve the exponential sum

$$f(\alpha) = f_k(\alpha, X) = \sum_{x_i \leq X_i \atop 1 \leq i \leq k} e(\alpha(x)^d)$$

in which $X \in [1, \infty)^k$. The case $k = 1$ is that of classical Weyl sums, with an extensive literature. Little appears to be available for $k \geq 2$, forcing us to rework the most basic theory of Weyl sums in the new context. The simplest principles will be sufficient for our purposes. Most of our estimates may be improved, but such refinements will not be needed here. Throughout this section vectors are of dimension $k$.

#### 3.2. Approximate formulae.

For $q \in \mathbb{N}$ and $X$ as above let $E(q, X)$ be the symmetric function in $X_1, \ldots, X_k$ that, whenever

$$X_1 \geq X_2 \geq \ldots \geq X_k$$

holds, is defined by

$$E(q, X) = q^k + \sum_{r=1}^{k-1} q^{k-r} X_1 \cdots X_r.$$
We also define the complete Weyl sum

\[(3.4) \quad S(q, a) = \sum_{x_i \equiv 1 \mod q} e(a(x)^d / q).\]

Only in cases where \(k\) varies this will be indicated by writing \(E_k\) or \(S_k\).

**Lemma 3.1.** Whenever \(a \in \mathbb{Z}, q \in \mathbb{N}\) and \(X \in [1, \infty)^k\), one has

\[f_k(a/q, X) = q^{-k} S(q, a) \langle X \rangle + O(E(q, X)).\]

**Proof.** By symmetry, we may suppose that \((3.2)\) holds. Now sort the \(x_j\) in \((3.1)\) into residue classes modulo \(q\) to confirm that

\[f\left(\frac{a}{q}\right) = \sum_{b=1}^{q} e\left(\frac{a(b)^d}{q}\right) \sum_{x \equiv b \mod q} 1 = S(q, a) \prod_{j=1}^{k} \left(\frac{X_j}{q} + O(1)\right).\]

The product of all \(X_j/q\) yields the leading term while an inspection of \((3.3)\) shows that all other terms are bounded by \(E(q, X)\).

We now apply partial summation to evaluate \(f(a/q + \beta)\). This features the function

\[(3.5) \quad v(\beta) = v_k(\beta, X) = \int_{0}^{X_k} \cdots \int_{0}^{X_k} e(\beta(t)^d) dt_1 \cdots dt_k.\]

**Lemma 3.2.** Whenever \(a \in \mathbb{Z}, q \in \mathbb{N}, \beta \in \mathbb{R}\) and \(X \in [1, \infty)^k\), one has

\[f_k\left(\frac{a}{q} + \beta, X\right) = q^{-k} S(q, a) v(\beta) + O\left(E(q, X)(1 + \langle X \rangle^d |\beta|)^k\right).\]

**Proof.** Notation is the most difficult part of the otherwise routine argument. Throughout this proof, let \(S\) denote a subset of \(\{1, 2, \ldots, k\}\), and write \(S^c = \{1, \ldots, k\} \setminus S\). As on earlier occassions, for \(t \in [1, \infty)^k\), let \(t_S = (t_j)_{j \in S}\). Also, for \(t, u \in [1, \infty)^k\), let \((u, t)_{\mathcal{S}}\) be the vector \((z_1, \ldots, z_l)\) with

\[z_j = t_j \quad \text{for} \ j \in S, \quad z_j = u_j \quad \text{for} \ j \in S^c.\]

In the interest of brevity, we also write

\[g(t) = e(\beta(t)^d),\]

and if \(S\) consists of the \(r\) numbers \(s_1, \ldots, s_r\), then we put

\[g^{(S)}(t) = \frac{\partial}{\partial t_{s_1}} \cdots \frac{\partial}{\partial t_{s_r}} g(t).\]

We are ready to apply partial summation to the sums over \(x_j\) in \((3.1)\). This produces

\[(3.6) \quad f\left(\frac{a}{q} + \beta\right) = g(X) f\left(\frac{a}{q}\right) + \sum_{S \neq \emptyset} (-1)^{\# S} \int_{W(S)} g^{(S)}((X, t)_S) f\left(\frac{a}{q}, (X, t)_S\right) dt_S\]

in which the sum over \(S\) runs over subsets of \(\{1, \ldots, k\}\), and \(W(S)\) denotes the cartesian product of the intervals \([1, X_j]\) with \(j \in S\). The term \(g(X) f(a/q)\) may be considered as the formal term \(S = \emptyset\) of the sum on the right.

We now apply Lemma \((3.1)\) to all summands on the right hand side of \((3.6)\). The leading terms that arise reassemble to

\[(3.7) \quad q^{-k} S(q, a) \sum_{S \neq \emptyset} (-1)^{\# S} \int_{W(S)} g^{(S)}((X, t)_S) (X_S)(t_S) dt_S,\]
with the summand $\mathcal{S} = \emptyset$ to be read as $g(X)(X)$. If the formal partial integration
$$\int_0^X h(t) \, dt = X h(X) - \int_0^X t h'(t) \, dt$$
is applied to all integrations in (3.6), then one finds that
$$v(\beta) = g(X)(X) + \sum_{\mathcal{S} \neq \emptyset} (-1)^{\#\mathcal{S}} \langle X \rangle \int_{W(\mathcal{S})} \langle t, \mathcal{S} \rangle g(\mathcal{S})((X, t), \mathcal{S}) \, dt.$$
Hence, the sum in (3.7) is exactly the leading term on the right hand side of the formula in Lemma 3.2.

It remains to control the error terms that arise from the use of Lemma 3.1 in (3.6). The transition from $g(X)f(a/q)$ to $q^{-k} S(q, a)(X)g(X)$ results in an error bounded by $E(q, X)$, which is acceptable. For the remaining terms, first note that for $1 \leq r \leq k$ there are natural numbers $b_{r,j}$ with
$$\frac{\partial}{\partial t_1} \cdots \frac{\partial}{\partial t_r} g(t) = d' g(t) \sum_{j=1}^{\#\mathcal{S}} b_{r,j} (2\pi i \beta)^j \frac{\langle t \rangle^{jd}}{t_1 \cdots t_r},$$
as one readily confirms by induction on $r$. Hence, by symmetry, it follows that whenever $\mathcal{S}$ is non-empty, one has
$$g(\mathcal{S})(t) \ll \sum_{j=1}^{\#\mathcal{S}} \langle \beta \rangle^j \frac{\langle t \rangle^{jd}}{\langle t, \mathcal{S} \rangle}.$$ 
Moreover, we note that for $t, \mathcal{S} \in W(\mathcal{S})$ one has
$$E(q, (X, t), \mathcal{S}) \leq E(q, X).$$
Hence, the insertion of the asymptotic relation from Lemma 3.1 into (3.6) is at the cost of an error not exceeding
$$\ll E(q, X) \int_{W(\mathcal{S})} |g(\mathcal{S})((X, t), \mathcal{S})| \, dt, \mathcal{S}$$
$$\ll E(q, X) \sum_{j=1}^{\#\mathcal{S}} \langle \beta \rangle^j \langle X \rangle^{jd} \int_{W(\mathcal{S})} \langle t, \mathcal{S} \rangle^{jd-1} \, dt,$$
$$\ll E(q, X) \sum_{j=1}^{\#\mathcal{S}} \langle \beta \rangle^j \langle X \rangle^{jd}.$$ 
Lemma 3.2 is now immediate.

Before we continue our study of the exponential sum (3.1), we briefly estimate the factors $S(q, a)$ and $v(\beta)$ in the leading term of the asymptotic expansion supplied by Lemma 3.2.

**Lemma 3.3.** Let $q \in \mathbb{N}$, $a \in \mathbb{Z}$ and $(a, q) = 1$. Then
$$q^{-k} S(q, a) \ll \tau(q)^{k-1} q^{-1/d}.$$ 
Moreover, when $a' \in \mathbb{Z}$, $q' \in \mathbb{N}$ are any numbers with $a/q = a'/q'$, then
$$q^{-k} S(q, a) = (q')^{-k} S(q', a').$$
Proof. By two applications of Lemma 5.1 we see that
\[ q^{-k}S(q, a) = \lim_{X \to \infty} X^{-k} f_k(a/q, (X, \ldots, X)), \]
and that this also holds with \( q', a' \) in place of \( q, a \). However, the right hand side here remains the same if \( a/q \) is replaced by \( a'/q' \). This already confirms the second clause in Lemma 3.3.

Turning our attention to the first clause, we note that the case \( k = 1 \) is a familiar estimate of Hardy and Littlewood. More precisely, for \( d \geq 2 \), it follows from Theorem 4.2 of [18] and the preceding remark that whenever \( b \in \mathbb{Z} \) and \( r \in \mathbb{N} \),
\[ r \sum_{x} e(bx^d/r) \ll r^{1-1/d} (r, b) \frac{1}{d}. \]
When \( d = 1 \), orthogonality evaluates the sum on the left here, and the bound remains valid. Hence, for \( k = 1 \), the proof of the lemma is complete, and for \( k \geq 2 \) and \((a, q) = 1\), we have
\[ q^{-k}S_k(q, a) = \sum_{x_2, \ldots, x_k = 1} q^{-k}S_1(q, a(x_2 \ldots x_k)^d) \ll q^{1-1/d} \sum_{x_2, \ldots, x_k = 1} (q, (x_2 \ldots x_k)^d)^{1/d} \ll q^{-1/d} \left( \sum_{x} \frac{(q, x)}{q} \right)^{k-1}. \]
The desired estimate is now immediate.

We close this section with an upper bound for the integral \( v_k(\beta, X) \) introduced in (3.5). Let
\[ V_k(\beta) = \int_{[0, 1]^k} e(\beta(t)^d) \, dt \]
which is the special case \( X_j = 1 \) (1 \( \leq j \leq k \)) of (3.5). An obvious substitution yields
\[ v_k(\beta, X) = (X) V_k((X)^d \beta). \]
By (3.8), one finds that
\[ V_k(\beta) \ll 1. \]
We now proceed to show that whenever \( |\beta| \geq 1 \), then
\[ V_k(\beta) \ll |\beta|^{-1/d} (1 + \log |\beta|)^{k-1}. \]
In fact, the bound \( V_1(\beta) \ll |\beta|^{-1/d} \) is immediate by partial integration (or explicit computation of the integral when \( d = 1 \)). We now proceed by induction on \( k \). By (3.8),
\[ V_{k+1}(\beta) = \int_0^1 V_k(\beta t^d) \, dt. \]
In the range \( 0 \leq t \leq |\beta|^{-1/d} \) we use (3.10) to see that these \( t \) contribute at most \( O(|\beta|^{-1/d}) \) to the integral in (3.12). With (3.11) at our disposal, it follows that
\[ V_{k+1}(\beta) \ll |\beta|^{-1/d} + \int_{|\beta|^{-1/d}}^1 |\beta|^{-1/d} t^{-1} (1 + \log(|\beta| t^d))^{k-1} \, dt. \]
This implies (3.11) with \( k + 1 \) in place of \( k \), completing the induction.
We may summarise the conclusions in (3.9), (3.10) and (3.11) in the following lemma.

**Lemma 3.4.** Let $X \in [1, \infty)^k$ and $\beta \in \mathbb{R}$. Then $v_k(\beta, X) \ll \langle X \rangle$, and whenever $|\beta| \geq \langle X \rangle^{-d}$, one has

$$v_k(\beta, X) \ll |\beta|^{-1/d} (1 + \log(\langle X \rangle^d |\beta|))^{k-1}.$$ 

3.3. **Bounds of Weyl’s type.** Our next goal is a crude form of Weyl’s inequality for the sum (3.1). This will then be coupled with the results of the previous section to provide suitable pointwise minor arc estimates. Throughout this section, we write

$$D = 2^{d-1}.$$

**Lemma 3.5.** Suppose that $X \in [1, \infty)^k$ satisfies (3.2). Let $\alpha \in \mathbb{R}$, $a \in \mathbb{Z}$, $q \in \mathbb{N}$ with $(a, q) = 1$ and $|q \alpha - a| \leq 1/q$. Then

$$|f(\alpha)|^D \ll \langle X \rangle^{D \varepsilon} \left( 1 + \frac{1}{X_k} + \frac{q}{\langle X \rangle^d} \right).$$

**Proof.** First suppose that $d = 1$. Then $D = 1$. We carry out the sum over $x_1$. Then, by a familiar divisor function estimate,

$$f(\alpha) \ll \sum_{x_1 \leq X_1, 2 \leq j \leq k} \min(X_1, \| \alpha x_2 \cdots x_j \|^{-1}) \ll \langle X \rangle \sum_{u \leq X_2 \cdots X_k} \min(X_1, \| \alpha u \|^{-1}).$$

The desired estimate now follows from Lemma 2.2 of Vaughan [18].

Next suppose that $d \geq 2$ and recall that Weyl’s differencing argument produces the inequality

$$(3.13) \quad \left| \sum_{y \leq Y} e(\gamma y^d) \right|^D \leq (2Y)^{D-d} \sum_{|h| \leq Y} \sum_{y \in I(h)} e(d!|h|y\gamma)$$

in which $h = (h_1, \ldots, h_{d-1})$ and $I(h)$ is the set of all $y \in \mathbb{N}$ with

$$1 \leq y \leq Y, \quad 1 \leq y + h_j \leq Y \quad (1 \leq j \leq d-1)$$

(see Vaughan [18], Lemma 2.3 and Exercise 2.8.1). We now prove by induction on $k$ that

$$(3.14) \quad |f_k(\alpha, X)|^D \leq (2^k \langle X \rangle)^{D^k - d} \sum_{|h_1| < X_1, x_1 \in I_1(h_1)} \cdots \sum_{|h_k| < X_k, x_k \in I_k(h_k)} e\left( (d!)^k \alpha \prod_{j=1}^k (h_j)x_j \right)$$

where $h_j \in \mathbb{Z}^{d-1}$, and $I_j(h_j)$ is a certain interval contained in $[1, X_j]$. In fact, the case $k = 1$ is (3.13) with $Y = X_1$, $\gamma = \alpha$. If $k \geq 2$ and (3.14) is already confirmed for $k - 1$ in place of $k$, then one first applies Hölder’s inequality to the identity

$$f_k(\alpha, X) = \sum_{x_k \leq X_k} f_{k-1}(\alpha x_k^d, (X_1, \ldots, X_{k-1}))$$

to infer that

$$|f_k(\alpha, X)|^D \leq |X_k|^{D^k - D} \left( \sum_{x_k \leq X_k} |f_{k-1}(\alpha x_k^d, (X_1, \ldots, X_{k-1}))|^{D^{k-1}} \right)^D,$$
and is then in a position to apply the induction hypothesis to \( f_{k-1}(\alpha x_k^d, (X_1, \ldots, X_{k-1})) \). This yields
\[
|f_k(\alpha, X)|^{D^k} \leq X_k^{D^k-D} (2^{k-1} X_1 \cdots X_{k-1})^{D^k-D} \left( \sum_{|h_j| < X_j} \sum_{x_j \in I_j(h_j)} e(\alpha \Phi) \right)^D
\]
with
\[
\Phi = (dt)^{k-1} x_k^{d} \prod_{j=1}^{k-1} (h_j) x_j.
\]
Here, the innermost sum over \( x_k \) is again an ordinary \( d \)-th power Weyl sum. By Hölder’s inequality again, we first deduce that
\[
|f_k(\alpha, X)|^{D^k} \leq X_k^{D^k-D} (2^{k-1} X_1 \cdots X_{k-1})^{D^k-d} \sum_{|h_j| < X_j} \sum_{x_j \in I_j(h_j)} e(\alpha \Phi) \left| \sum_{x_k \leq X_k} e(\alpha \Phi) \right|^D,
\]
and may then apply (3.13) to arrive at (3.14), thus completing the induction.

Now consider the product
\[
u = (dt)^k \prod_{j=1}^{k} (h_j) x_j
\]
that occurs in (3.14). With \( h_j, x_j \) subject to the conditions of summation in (3.14), one has \( \nu = 0 \) if and only if one of the components of some \( h_j \) vanishes. Hence, by (3.2), the number of such \( h_j, x_j \) where \( \nu = 0 \) is bounded by \( \langle X \rangle^{d^k} X_k^{-1} \), and the contribution of these terms to (3.14) amounts to \( O(\langle X \rangle^{D^k} X_k^{-1}) \) which is acceptable. For the remaining terms, we write \( \nu = x_1 \) and sum over \( x_1 \) first. A divisor function estimate then delivers the bound
\[
|f_k(\alpha, X)|^{D^k} \ll \langle X \rangle^{D^k} X_k^{-1} + \langle X \rangle^{D^k+\varepsilon-d} \sum_{1 \leq m \leq M} \min(X_1, \| \alpha m \|^{-1})
\]
in which \( M = (dt)^k \langle X \rangle^{d^k} X_k^{-1} \). The conclusion of Lemma 3.5 is now immediate from Lemma 2.2 of [18].

In preparation for two applications of the Hardy-Littlewood method, we introduce a dissection into major and minor arcs. From now on, we write
\[
(3.15) \quad P = \langle X \rangle.
\]
With \( Q \) in the range \( 1 \leq Q \leq P^{1/(dk)} \), let \( \mathfrak{N}(Q) \) denote the union of the pairwise disjoint intervals \( |qa - a| \leq Q P^{-d} \) with \( a, q \) subject to \( 1 \leq q \leq Q, a \in \mathbb{Z} \) and \( (a, q) = 1 \). Let \( n(Q) = \mathbb{R} \setminus \mathfrak{N}(Q) \) and define \( \mathfrak{M}(Q) \) and \( m(Q) \) by
\[
\mathfrak{M}(Q) = \mathfrak{N}(Q) \cap [0, 1], \quad m(Q) = n(Q) \cap [0, 1].
\]

**Lemma 3.6.** Given natural numbers \( d, k \), let
\[
\omega = (8dk)^{-8}, \quad \eta = \omega/(2D^k dk).
\]
Then
\[
\sup_{\alpha \in n(P^\omega)} |f_k(\alpha, X)| \ll P^{1-\eta}.
\]
Proof. By symmetry, we may suppose that (3.2) holds. There are two cases, depending on the relative size of the $X_r$.

First suppose that $X_k \geq P^{\omega/(dk)}$. By Dirichlet’s theorem, choose coprime integers $a, q$ with $1 \leq q \leq P^{d-\omega}$ and $|aq - a| \leq P^{\omega-d}$. Since $\alpha \in \mathfrak{n}(P^\omega)$, it follows that $q > P^\omega$. Lemma 3.3 now yields $f_k(\alpha, X) \ll P^{1-2\eta+\epsilon}$.

It remains to consider the case where $X_k < P^{\omega/(dk)}$. By (3.2), one has $X_1 \geq P^{1/k}$, and hence, there is a number $r$ with $1 \leq r \leq k - 1$ and

$$X_r \geq P^{\omega/(dk)} > X_{r+1}.$$  

We write $Y = (X_1, \ldots, X_r)$ and $Z = (X_{r+1}, \ldots, X_k)$. Then, by (3.17),

$$f_k(\alpha, X) = \sum_{z \leq Z} f_r(\alpha\langle z \rangle^d, Y).$$

Now consider $z$ with $z \leq Z$. By Dirichlet’s theorem, there are coprime $a = a(z)$, $q = q(z)$ with $1 \leq q \leq P^{d-\omega}$ and $|qz^k\alpha - a| \leq P^{\omega-k}$. Note that (3.16) implies

$$|z| \leq (Z) \leq P^\omega(\log P)(dk).$$

Hence, for $q \leq P^{\omega/k}$, it follows that $|qz^d| \leq P^\omega$, so that $\alpha \in \mathfrak{n}(P^\omega)$. This is not the case. Consequently, we may conclude that we must have $q > P^{\omega/k}$, and Lemma 3.3 yields

$$|f_r(\alpha\langle z \rangle^d, Y)|^{D^r} \ll (Y)^{D^r+\epsilon} \frac{1}{q} + \frac{1}{X_r} + \frac{q}{(Y)^d} \ll (Y)^{D^r+\epsilon} (P^{-\omega/(dk)} + (Z)^d P^{-\omega}) \ll (Y)^{D^r+\epsilon} P^{-\omega/(dk)}.$$ 

In the last line, we have used (3.18). We take the $D^r$-th root and then sum over $z$. By (3.17), it follows that $f_k(\alpha, X) \ll P^{1-\eta}$. This completes the proof.

Lemma 3.7. Let $d, k, \omega, \eta$ be as in the previous lemma, and let $s$ be a natural number. Suppose that (3.2) holds. Put $U = X_k^{\omega/s}$. Then

$$\sup_{\alpha \in \mathfrak{n}(U)} |f_k(\alpha, X)| \ll P^{1-\eta} + PU^{-1/(5dk)}.$$ 

Proof. Note that $X_k \leq P^{1/k}$ so that $U \leq P^\omega$. Whenever $\alpha \in \mathfrak{n}(P^\omega)$, then Lemma 3.6 supplies a satisfactory bound. Hence, we may concentrate on the case where $\alpha \in \mathfrak{n}(P^\omega) \cap \mathfrak{n}(U)$.

Recall that $X_1 \geq P^{1/k}$. Also, note that $3k^4\omega < 1/k$. Consequently, in the current situation, there is a number $r$ with $1 \leq r \leq k - 1$ and

$$X_r \geq P^{3k^4\omega} > X_{r+1}.$$ 

Note that this implies $k \geq 2$. With this new definition of $r$, we use the identity (3.17) from the previous proof. The estimation now proceeds through the inequality

$$|f(\alpha)| \leq \sum_{z \leq Z} |f_r(\alpha\langle z \rangle^d, Y)|,$$

where we use the results from the preceding section to bound $f_r(\alpha\langle z \rangle^d, Y)$. Since $\alpha \in \mathfrak{n}(P^\omega)$, there is a unique pair $a, q$ with $1 \leq q \leq P^\omega$, $a \in \mathbb{Z}$, $(a, q) = 1$ and $a = (a/q) + \beta$ satisfying $|q\beta| \leq P^{\omega-d}$. We use Lemma 3.2 with $r$ in place of $k$, and with $a$ and $\alpha$ replaced by $\alpha\langle z \rangle^d$, $\alpha\langle z \rangle^d$. Then, by a crude use of Lemmas 3.3 and 3.4, one finds that

$$f_r(\alpha\langle z \rangle^d, Y) \ll (q, \langle z \rangle^d)^{1/d}\langle Y \rangle(q + q\langle Y \rangle^d\langle z \rangle^d|\beta|)^{-1/d} + E(q, Y)(1 + \langle Y \rangle^d\langle z \rangle^d|\beta|)^{\epsilon}.$$
Here, we first concentrate on the second term on the right hand side. For $z \leq Z$, the upper bound on $|\beta|$ guarantees that
\[ 1 + (Y)^d(z)^d|\beta| \leq 1 + P^d|\beta| \leq 2P^\omega q^{-1}. \]
Moreover, in the current context, we have $q \leq P^\omega \leq X_j$ for all $j \leq r$, so that (3.21) now shows
\[ E(q, Y)(1 + (Y)^d(z)^d|\beta|)^r \leq 2^r P^{r\omega} \sum_{j=0}^{r-1} q^{-j} \prod_{i=1}^r X_i. \]
Here, the right hand side does not exceed $O((Y)X^{-1}P^{\omega})$, and by the definition of $r$ this is bounded by $O((Y)P^{-\omega})$. We now insert the results obtained so far into (3.19) and find that
\[ f(\alpha) \ll P^{1-\omega} + (Y)q^{1-1/d} \sum_{z \leq Z} (q, (z))(1 + (Y)^d(z)^d|\beta|)^{-1/d} \]
\[ \ll P^{1-\omega} + \min \left( (Y)q^{1-1/d} \sum_{z \leq Z} (q, (z)), (Y)^{1/d} |\beta|^{1-1/d} \sum_{z \leq Z} (q, (z))(z)^{d-1} \right). \]
The simple estimate
\[ \sum_{z \in \mathbb{Z}} (q, (z)) \leq \prod_{j=r+1}^k \sum_{x_j \leq X_j} (q, x_j) \ll q^{\varepsilon} \mathbb{Z} \]
and partial summation now show that
\[ f(\alpha) \ll P^{1-\omega} + Pq^{1-1/d} + P^{d\varepsilon}|q\beta|^{1-1/d} \]
For $\alpha \in \mathbb{R}(U)$, we have $q > U$ or $q|\beta| > UP^{-d}$, and the lemma follows.

3.4. A mean value estimate. The mean value (1.3) defining $n_0(d)$ may play the role of Hua’s lemma in an investigation of diagonal forms via the circle method. We need a similar bound for Weyl sums over products. In fact, because the number of solutions of $\langle x \rangle = m$ with $x \in \mathbb{N}^k$ is $O(m^\varepsilon)$, a consideration of the underlying diophantine equations shows that
\[ \int_0^1 |f_k(\alpha, X)|^{n_0(d)} \, d\alpha \ll (X)^{\varepsilon} \int_0^1 |f_1(\alpha, \langle X \rangle)|^{n_0(d)} \, d\alpha \ll (X)^{n_0(d) - d + 2\varepsilon}. \]
In cases where some of the $X_j$ are considerably smaller than $\langle X \rangle^\varepsilon$ this estimate is insufficient for our purposes. The following lemma provides an alternative bound, free of the unwanted $\varepsilon$ in (3.21).

**Lemma 3.8.** Fix a real number $\sigma > n_0(d)$. Then, for $X \in [1, \infty)^k$ one has
\[ \int_0^1 |f_k(\alpha, X)|^\sigma \, d\alpha \ll (X)^{\sigma - d}. \]

**Proof.** By symmetry, we may suppose that (3.2) holds. Recall that this implies $X_1 \geq P^{1/k}$ where $P$ is defined by (3.15). Also, let $\omega$ be as in Lemma 3.6. Now, by that lemma and (3.21), one has
\[ \int_{m(P^{\omega})} |f(\alpha)|^\sigma \, d\alpha \leq \sup_{\alpha \in m(P^{\omega})} |f(\alpha)|^{\sigma - n_0} \int_0^1 |f(\alpha)|^{n_0} \, d\alpha \ll P^{\sigma - d}. \]
It remains to consider the major arcs \( \mathfrak{M}(P^\omega) \) where one uses (3.17) with \( r = 1 \) and \( \mathbf{Z} = (X_2, \ldots, X_k) \). If \( \alpha \in \mathfrak{M}(P^\omega) \), let \( a, q \) be the unique pair \( a, q \) with \( 1 \leq q \leq P^\omega \), \( (a, q) = 1 \) and \( \alpha = a/q + \beta \) satisfying \( q|\beta| \leq P^{\omega - d} \). Then, by Lemma 3.2
\[
f(\alpha) = \sum_{z \leq \mathbf{Z}} \left( q^{-1} S_1(q, a(z)^d) v_1(\beta(z)^d, X_1) + O\left(q(1 + X_1^d |\beta|)\right)\right),
\]
and for \( \alpha \in \mathfrak{M}(P^\omega) \) one has \( q(1 + X_1^d |\beta|) \ll P^\omega \). Hence, on writing
\[
H(q, \beta) = \sum_{z \leq \mathbf{Z}} (q, z) \min(X_1, |z|^{-1} |\beta|^{-1/d}),
\]
one now infers from Lemmas 3.3 and 3.4 that
\[
H(q, \beta) \leq X_1 \sum_{z \leq \mathbf{Z}} (q, z) \ll Pq^\epsilon.
\]
The previous bound for \( f \) now delivers
\[
f(\alpha) \ll q^{-1/d} H(q, \beta) + (\mathbf{Z}) P^\omega \ll q^{-1/d} H(q, \beta) + P^{1 - 1/(2k)},
\]
as is apparent from the lower bound on \( X_1 \). By (3.24),
\[
H(q, \beta) \leq X_1 \sum_{z \leq \mathbf{Z}} (q, z) \ll Pq^\epsilon.
\]
The previous bound for \( f \) now delivers
\[
f(\alpha) \ll Pq^{-1/d} + P^{1 - 1/(2k)} \ll Pq^{-1/(2d)}
\]
uniformly for \( \alpha \in \mathfrak{M}(P^\omega) \). Since \( n_0(d) \geq 2d \), we may use (3.23) for \( 2d \) copies of \( f \) and (3.24) for the rest to confirm that
\[
|f(\alpha)|^\sigma \ll (Pq^{-1/2d})^{\sigma - 2d}(q^{-2} H(q, \beta)^{2d} + P^{2d - (d/k)}).
\]
The measure of \( \mathfrak{M}(P^\omega) \) is \( O(P^{2\omega - d}) \). Hence, on integrating the previous inequality, we infer that
\[
\int_{\mathfrak{M}(P^\omega)} |f(\alpha)|^\sigma d\alpha \ll P^{\sigma - 2d} I + P^{\sigma - d - 1/(2k)}
\]
where
\[
I = \sum_{q \leq P^\omega} q^{-\sigma/(2d)} \int_{-\infty}^{\infty} H(q, \beta)^{2d} d\beta.
\]
Now
\[
\int_{-\infty}^{\infty} H(q, \beta)^{2d} d\beta = \sum_{z \leq \mathbf{Z}} (q, z_1) \cdots (q, z_{2d}) \int_{-\infty}^{\infty} \prod_{j=1}^{2d} \min(X_1, |z|^{-1} |\beta|^{-1/d}) d\beta.
\]
By Hölder’s inequality and (3.24), it follows that
\[
\int_{-\infty}^{\infty} H(q, \beta)^{2d} d\beta \leq \left( \sum_{z \leq \mathbf{Z}} (q, z) \left( \int_{-\infty}^{\infty} \min(X_1^{2d}, |z|^{-2d} |\beta|^{-2}) d\beta \right)^{1/(2d)} \right)^{2d}
\]
\[
\ll \left( \sum_{z \leq \mathbf{Z}} (q, z) X_1^{1/2}(z)^{-1/2} \right)^{2d}
\]
\[
\ll \left( q_1 X_1^{1/2}(z)^{1/2} \right)^{2d} \ll P^d q^{2d \epsilon}.
\]
Since \( \sigma > 2d \), one now first confirms that \( I \ll P^d \), and then that
\[
\int_{\mathfrak{M}(P^\omega)} |f(\alpha)|^\sigma d\alpha \ll P^{\sigma - d}.
\]
The lemma follows on combing this bound with (3.22).
4. Multihomogeneous diagonal forms

4.1. The auxiliary theorem. In the present chapter we consider integer solutions of equations similar to (1.1). Fix natural numbers \(d, k, s\). Let \(c_j \in \mathbb{Z} \setminus \{0\}\) for \(1 \leq j \leq s\). With \(x_j \in \mathbb{Z}^k\), consider the diophantine equation

\[
\sum_{j=1}^s c_j \langle x_j \rangle^d = 0.
\]

For \(X \in [1, \infty)^k\), let \(M_c(X)\) denote the number of solutions of (4.1) with

\[
1 \leq |x_{j,r}| \leq X_r \quad (1 \leq j \leq s, 1 \leq r \leq k),
\]

and let \(M_c^+(X)\) be the number of the solutions with all \(x_{j,r}\) positive.

Theorem 4.1. Let \(s > n_0(d)\). Then, there is a positive number \(\delta\) such that whenever \(c_j \in \mathbb{Z} \setminus \{0\}\), there are non-negative real numbers \(E(c), E^+(c)\) with

\[
M_c(X) = E(c)\langle X \rangle^{s-d} + O(\langle X \rangle^{s-k} (\min X_i)^{-\delta}|c|^{s+k})
\]

and

\[
M_c^+(X) = E^+(c)\langle X \rangle^{s-d} + O(\langle X \rangle^{s-k} (\min X_i)^{-\delta}|c|^{s+k}).
\]

Further, the number \(E(c)\) is positive if and only if the equation

\[
c_1y_1^d + \ldots + c_sy_s^d = 0
\]

admits non-trivial solutions in \(\mathbb{R}\) and in \(\mathbb{Q}_p\) for all primes \(p\). Also, \(E^+(c)\) is positive if and only if (4.4) has non-trivial solutions in \(\mathbb{Q}_p\) for all primes \(p\), and in positive real numbers.

Note that we claim the asymptotic formulae (4.2) and (4.3) with error terms that are uniform in \(c\). However, we will make no attempt to estimate the leading term from below in terms of \(c\), as this is not required later.

We shall prove (4.3) by a straightforward application of the circle method in Section 4.3 below, and then deduce (4.2) by a combinatorial observation in Section 4.4. As is to be expected, the constants \(E(c), E^+(c)\) turn out to be the product of the singular series and the singular integral associated with the respective counting problem. These natural interpretations of \(E(c)\) and \(E^+(c)\) can be used to establish our claims concerning positivity of these numbers. We prepare a swift treatment of the local part of our circle method work with a discussion of this matter in section 4.2. Once Theorem 4.1 is established, we close this chapter with a brief treatment of primitive solutions counted by \(M_c(X)\).

4.2. Singular series and integral. In preparation for the circle method work in the following section, we define and estimate the singular series and the singular integral for the equation (1.1). We use the notation introduced in section 3.2. Fix a natural number \(k\). Throughout this section, let \(c_1, \ldots, c_s\) be non-zero integers. Now recall (3.4) and put

\[
T_c(q) = q^{-ks} \sum_{\substack{a=1 \atop (a,q)=1}}^q \prod_{j=1}^s S_k(q, ac_j).
\]

Then, by Lemma 3.3,

\[
T_c(q) \ll q^{1-(s/d)+\varepsilon}(q, c_1)^{1/d} \cdots (q, c_s)^{1/d} \ll q^{1-(s/d)+\varepsilon}|c|^{s/d}.
\]
It follows that whenever $s > 2d$, the singular series
\begin{equation}
\mathcal{S}(c) = \mathcal{S}_k(c) = \sum_{q=1}^\infty T_c(q)
\end{equation}
converges absolutely, and one has
\begin{equation}
\mathcal{S}(c) \ll |c|^{s/d}.
\end{equation}
Moreover, for the partial sum
\begin{equation}
\mathcal{S}(c, W) = \sum_{q \leq W} T_c(q)
\end{equation}
we also have
\begin{equation}
\mathcal{S}(c, W) = \mathcal{S}(c) + O(W^{-1/(2d)}|c|^{s/d}).
\end{equation}

These immediate estimates already suffice within the analysis to be performed in the next section. We now show that $\mathcal{S}(c)$ is a product of local densities. In fact, by the argument underpinning the proof of Lemma 2.11 in Vaughan [18], one finds that $T_c(q)$ is multiplicative in $q$. Hence, $\mathcal{S}(c)$ can be written as an Euler product, and by a suitable analogue of Lemma 2.12 of Vaughan [18], one may compute the Euler factors. This yields
\begin{equation}
\mathcal{S}(c) = \prod_p E_p(c)
\end{equation}
where
\begin{equation}
E_p(c) = \sum_{l=0}^\infty T_c(p^l) = \lim_{L \to \infty} p^{L(1-k_s)} \Phi_c(p^L),
\end{equation}
and in which $\Phi_c(q)$ denotes the number of incongruent solutions to
\begin{equation}
\sum_{j=1}^s c_j \langle x_j \rangle^d \equiv 0 \mod q.
\end{equation}
In particular, the number $\mathcal{S}(c)$ is non-negative.

Now suppose that the equation $\mathcal{S}$ has a non-trivial solution in $\mathbb{Q}_p$. Since $\mathcal{S}$ is homogeneous, there will be a solution $\mathbf{y} \in \mathbb{Z}_p^s$ with $p \nmid \mathbf{y}$. By symmetry, we may suppose that $p \nmid y_1$. The theory of $d$-th power residues supplies a natural number $\gamma$ with the property that for all integers $b$ for which the congruence $c_1 z^d \equiv b \mod p^\gamma$ has a solution with $p \nmid z$, the allied congruences $c_1 z^d \equiv b \mod p^L$ are also soluble with $p \nmid z$, for all $L > \gamma$. Now choose integers $z_j$ with $z_j \equiv y_j \mod p^\gamma$. Then $p \nmid z_1$. Now put $\mathbf{z} = (z_1, 1, 1, \ldots, 1)$. Then, observing that $z_j = \langle \mathbf{z}_j \rangle$, we infer
\begin{equation}
c_1(z_1)^d + \ldots + c_s(\mathbf{z}_s)^d \equiv 0 \mod p^\gamma.
\end{equation}
Let $L > \gamma$, and choose $\mathbf{x}_2, \ldots, \mathbf{x}_s$ modulo $p^L$ with $\mathbf{x}_j \equiv \mathbf{z}_j \mod p^\gamma$. There are $p^{(L-\gamma)k(s-1)}$ choices for $\mathbf{x}_2, \ldots, \mathbf{x}_s$ that are incongruent modulo $p^L$. By construction,
\begin{equation}
c_1 z_1^d \equiv -c_2(\mathbf{x}_2)^d - \ldots - c_s(\mathbf{x}_s)^d \mod p^\gamma,
\end{equation}
and hence there is a number $z$ with $p \nmid z$ and
\begin{equation}
c_1 z^d \equiv -c_2(\mathbf{x}_2)^d - \ldots - c_s(\mathbf{x}_s)^d \mod p^L,
\end{equation}
It follows that any $x_1$ with $\langle x_1 \rangle \equiv z \mod p^L$ yields a solution of (4.11), and there are $\phi(p^L)^k - 1$ such $x_1$ that are incongruent, modulo $p^L$. This proves that

$$\Phi_c(p^L) \geq \phi(p^L)^k - 1 p^{(L-1)(s-1)}.$$ 

By (4.10), we conclude that $E_p(c) > 0$ whenever (4.4) has non-trivial solutions in $\mathbb{Q}_p$. Since the product in (4.9) converges absolutely, we may conclude as follows.

Lemma 4.2. Let $s > 2d$. Then, for all natural numbers $k$, the singular series (4.5) is real and non-negative. If the equation (4.4) admits non-trivial solutions in $\mathbb{Q}_p$ for all primes $p$, then the singular series is positive.

We now turn to the singular integral. Note that the function $t^{-1/d}(1 + \log t)$ is decreasing on the interval $t \geq 3$. Hence when $|\beta| \geq 3$, we infer from (3.11) that the function

$$\mathcal{U}_c(\beta) = V_k(c_1\beta)V_k(c_2\beta)\ldots V_k(c_s\beta)$$

obeys the inequality

$$\mathcal{U}_c(\beta) \ll |\beta|^{-s/d}(1 + \log |\beta|)^{(k-1)}$$

uniformly in $c$. Similarly, (3.10) gives $\mathcal{U}_c(\beta) \ll 1$. Hence, for $s > 2d$, the singular integral

$$\mathcal{I}^+(c) = \mathcal{I}^+_k(c) = \int_{-\infty}^{\infty} \mathcal{U}_c(\beta) \, d\beta$$

exists, and one has

$$\mathcal{I}^+(c) \ll 1$$

uniformly with respect to $c$. By (4.12), we also see that whenever $s > 2d$ and $W \geq 3$ one has

$$\int_{-W}^{W} |\mathcal{U}_c(\beta)| \, d\beta \ll W^{-1}.$$ 

Thus, the truncated singular integral

$$\mathcal{I}^+(c, W) = \int_{-W}^{W} \mathcal{U}_c(\beta) \, d\beta$$

compares to (4.13) through

$$\mathcal{I}^+(c, W) = \mathcal{I}^+(c) + O(W^{-1}).$$

Again, these simple estimates will suffice for our purposes. The arithmetical nature of $\mathcal{I}^+(c)$ is the subject of the next lemma.

Lemma 4.3. Let $s > 2d$. Then, for all natural numbers $k$, the singular integral (4.13) is real and non-negative. If the $c_j$ are not all of the same sign, then the singular integral is positive.

Proof. The classical case $k = 1$ has been worked out by Davenport [8], chapters 4 and 10. Although the set-up there is slightly different from ours, Davenport’s argument immediately delivers the conclusions announced in Lemma 4.3. Hence, we now suppose that $k \geq 2$ and take up the story at (3.8) where we substitute $\nu = t_1^d t_2^d \ldots t_s^d$ for $t_1$. On writing $t' = (t_2, \ldots, t_s)$, we then have

$$V_k(\beta) = \frac{1}{d} \int_{[0,1]^{k-1}} (t')^{-1} \int_0^{(t')^d} \nu^{(1/d)-1} e(\beta \nu) \, d\nu \, dt'.$$
We may exchange the order of integration, as is most readily justified by Tonelli’s theorem. For a compact presentation of the outcome of this manœuvre, let \( \nu > 0 \) and put

\[
\Psi(\nu) = \{ t' \in [0, 1]^{s-1} : \langle t' \rangle^d \geq \nu \}, \quad \psi_k(\nu) = \nu^{(1/d) - 1} \int_{\Psi(\nu)} \frac{dt'}{\langle t' \rangle}.
\]

Note that \( \psi_k \) is integrable over \((0, 1]\), as one readily confirms. By (4.17), we now deduce that

\[
V_k(\beta) = \frac{1}{d} \int_0^1 \psi_k(\nu)e(\beta \nu) \, d\nu.
\]

By (4.12) and (4.13),

\[
\mathcal{J}^+(c) = d^{-s} \int_{-\infty}^{\infty} \int_{[0,1]^s} \psi_k(\nu_1) \cdots \psi_k(\nu_s) e(\beta c \cdot \nu) \, d\nu \, d\beta,
\]

where \( c \cdot \nu = c_1 \nu_1 + \cdots + c_s \nu_s \) is the standard inner product. Define \( t \) through the equation \( c_1 t = c \cdot \nu \) and substitute \( t \) for \( \nu_1 \) in the inner integral. This produces the identity

\[
\mathcal{J}^+(c) = d^{-s} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} B(t) e(c_1 \beta t) \, dt \, d\beta
\]

where

\[
B(t) = \int_{\mathcal{B}(t)} \psi_k(\nu_2) \cdots \psi_k(\nu_s) \psi_k \left( t - \frac{c' \cdot \nu'}{c_1} \right) \, d\nu',
\]

and therein we put

\[
\mathcal{B}(t) = \left\{ \nu' \in [0, 1]^{s-1} : 0 \leq t - \frac{c' \cdot \nu'}{c_1} \leq 1 \right\}.
\]

Note that \( B(t) \) is a compactly supported continuous function, whence by (4.18) and Fourier’s integral theorem, we infer that \( \mathcal{J}^+(c) = |c_1|^{-1} d^{-s} B(0) \). Since the integrand in (4.19) is non-negative, this implies that \( \mathcal{J}^+(c) \geq 0 \). Further, note that \( s > 2d \) implies that \( s \geq 3 \). Hence, if \( c_1, \ldots, c_s \) are not all of the same sign, we can permute the indices to arrange that \( c_2 \) and \( c_3 \) have opposite signs, say. It is then immediate from (4.20) that \( \mathcal{B}(0) \) contains a box of positive \( s - 1 \)-dimensional volume on which the integrand in (4.19) is continuous and positive, whence \( B(0) > 0 \). This completes the proof of the lemma.

We close this section with a remark concerning the product \( \mathcal{J}^+(c) \mathcal{G}(c) \). Suppose that that \( c \) is of the form \( c = ac' \) with \( a \in \mathbb{N} \) and \( c' \) primitive. Then, by (4.12), (4.13) and a change of variables, one has \( \mathcal{J}^+(c) = a^{-1} \mathcal{J}^+(c') \). Also, an inspection of (4.9), (4.10) and (4.11) reveals that \( \mathcal{G}(c) = a \mathcal{G}(c') \) so that

\[
\mathcal{J}^+(c) \mathcal{G}(c) = \mathcal{J}^+(c') \mathcal{G}(c').
\]

4.3. Positive solutions. Throughout this section we continue to use notational conventions from earlier sections of this chapter as well as those from Chapter 3. The object is to establish the asymptotic relation (4.3). We consider \( d, k \) as fixed and suppose that \( s > n_0(d) \). For any non-zero integers \( c_j \), we write

\[
F(\alpha) = f(c_1 \alpha) f(c_2 \alpha) \cdots f(c_s \alpha)
\]

where \( f(\alpha) \) is the exponential sum (3.1). Then, by orthogonality,

\[
M_c^s(X) = \int_0^1 F(\alpha) \, d\alpha.
\]
We evaluate $M^+_s(\mathbf{X})$ by the Hardy-Littlewood method. In doing so, we may suppose that (3.2) holds (by symmetry). Also, we suppose now that $(c_1: \ldots : c_s) = 1$.

Let $P$ be as in (3.15), and let $U$ be the parameter introduced in Lemma 3.7. Now put $W = U^s$.

Let $\mathcal{R}$ denote the disjoint union of the intervals

$\{\alpha \in [0, 1] : |\alpha - a/q| \leq WP^{-d}\}$

with $0 \leq a \leq q \leq W$ and $(a, q) = 1$. Let $t = [0, 1] \setminus \mathcal{R}$. For a one of the sets $\mathcal{R}, t$, we write

$I(a) = \int_a F(\alpha) d\alpha$

and then have

(4.22) $M^+_s(\mathbf{X}) = I(\mathcal{R}) + I(t)$.

For $1 \leq j \leq s$, consider the sets

$I_j = \{\alpha \in [0, 1] : c_j \alpha \in \mathbf{n}(U)\}$.

Suppose that $\alpha \in [0, 1]$ is in none of the $I_j$ ($1 \leq j \leq s$). Then, for all $j \leq s$, one has $c_j \alpha \in \mathcal{R}(U)$, and this shows that there are coprime $b_j \in \mathbb{Z}$, $r_j \in \mathbb{N}$ with $|c_j \alpha - (b_j/r_j)| \leq r_j^{-1}UP^{-d}$ and $r_j \leq U$. We now compare the various approximations

$$|\alpha - b_j/c_jr_j| \leq \frac{U}{|c_j|r_jP^d}.$$ 

For $1 \leq i < j \leq s$ one has

$$\left| \frac{b_j}{c_jr_j} - \frac{b_i}{c_ir_i} \right| \leq \frac{U}{P^d} \left( \frac{1}{|c_j|r_j} + \frac{1}{|c_i|r_i} \right),$$

whence

$$|c_i r_i b_j - c_j r_j b_i| \leq U P^{-d} (|c_i|r_i + |c_j|r_j) \leq 2U^2 P^{-d} |c| < 1$$

provided only that $|c| \leq P^{1/2}$, as we temporarily assume. Consequently, we may write $b_j/(c_jr_j) = a/q$ with $(a, q) = 1$, for all $1 \leq j \leq s$. Let $p^\nu | q$, with $\nu \geq 1$. Then, since $(c_1: \ldots : c_s) = 1$, there is a $j$ with $p \nmid c_j$. But $q|c_jr_j$ then implies $p^\nu|r_j$. It follows that $q|r_1r_2 \cdots r_s$, and hence that $q \leq U^s$. This shows that $\alpha \in \mathcal{R}$, and we may conclude that

$$I(t) \leq \sum_{j=1}^s \int_{b_j} \int_{t_j} |F(\alpha)| \, d\alpha.$$

An inspection of Lemma 3.7 shows that there is a $\delta > 0$ depending only on $d$, $k$ and $s$, and such that

$$\sup_{\alpha \in t} |f(c_1 \alpha)| \leq \sup_{\gamma \in \mathbf{n}(U)} |f(\gamma)| \ll P X_k^{-2\delta}.$$

Hence, on writing $\sigma = s - \frac{1}{2}$, Hölder’s inequality yields

$$\int_{t_1} |F(\alpha)| \, d\alpha \ll P^{1/2} X_k^{-\delta} \left( \int_0^1 |f(c_1 \alpha)|^\sigma \, d\alpha \right)^{1/(2\sigma)} \prod_{j=2}^s \left( \int_0^1 |f(c_j \alpha)|^\sigma \, d\alpha \right)^{1/\sigma}.$$

An obvious substitution and Lemma 3.8 yield

$$\int_0^1 |f(c_1 \alpha)|^\sigma \, d\alpha = \int_0^1 |f(\alpha)|^\sigma \, d\alpha \ll P^{\sigma - d},$$
which combines with the previous inequality to
\[ \int_{I_k} |F(\alpha)| \, d\alpha \ll P^{s-d}X_k^{-\delta}. \]
By symmetry, the same bound holds with \( I_1 \) replaced by any other \( I_j \), so that may now conclude that
\[ I(\mathfrak{a}) \ll P^{s-d}X_k^{-\delta}. \]

We may now concentrate on the major arcs \( \mathfrak{A} \). For \( \alpha \in \mathfrak{A} \), there is a unique pair \( a, q \) of coprime integers with \( 0 \leq a \leq q \), \( 1 \leq q \leq W \) and \( \alpha = (a/q) + \beta \) satisfying \( |\beta| \leq WP^{-d} \).

Lemma 3.2 gives
\[ f(c_j\alpha) = q^{-k}S(q, ac_j)v(c_j\beta) + O(E(q, X)(|c_j|W)^k). \]
For the leading term on the right hand side, crude use of Lemmas 3.3 and 3.4 supply the trivial upper bound
\[ O \]
\[ (4.25) \]
\[ F(\alpha) = q^{-k}s \prod_{j=1}^{s} S(q, ac_j)v(c_j\beta) + O(P^{-1}E(q, X)|c|^k W^k). \]

By (4.23), whenever \( q \leq W \) one has \( E(q, X) \ll PWX_k^{-1} \), and the measure of \( \mathfrak{A} \) is \( O(W^3P^{-d}) \). Hence, on integrating (4.25) over \( \mathfrak{A} \), one infers that
\[ I(\mathfrak{A}) = \mathfrak{S}_k(c, W) \int_{WP^{-d}} v(c_1\beta) \ldots v(c_s\beta) \, d\beta + O(P^{s-d}W^{k+4}X_k^{-1}|c|^k) \]
where \( \mathfrak{S}_k(c, W) \) is given by (4.7). Within the integral on the right hand side, we use (3.9), then substitute \( \beta \) for \( P^k\beta \) and recall (4.15) to recast the previous display in the form
\[ I(\mathfrak{A}) = \mathfrak{S}_k(c, W)\mathfrak{J}_k^+(c, W)P^{s-d} + O(P^{s-d}W^{k+4}X_k^{-1}|c|^k). \]
By (4.10), (4.8), (4.14) and (4.16),
\[ \mathfrak{S}_k(c, W)\mathfrak{J}_k^+(c, W) = \mathfrak{S}_k(c)\mathfrak{J}_k^+(c) + O(W^{-1/(2d)}|c|^s/d). \]
We now define
\[ \mathfrak{E}^+(c) = \mathfrak{S}_k(c)\mathfrak{J}_k^+(c), \]
and then first deduce from (4.26) that
\[ I(\mathfrak{A}) = \mathfrak{E}^+(c)P^{s-d} + O(P^{s-d}X_k^{-\delta}|c|^{s+k}) \]
holds for some sufficiently small positive \( \delta \), and further, from (4.23) and (4.22) that indeed (4.3) is valid. Along the way we have assumed that \( |c| \leq P^{1/2} \). However, in the contrary case, the condition that \( s > 2d \) implies that \( P^{s-d}X_k^{-\delta}|c|^{s+k} \gg P^s \), which shows that again (4.3) holds, this time for trivial reasons. This completes the proof of (4.3) when \( c \) is primitive.

Now suppose that \( c \) is not primitive, and that \( c = ac' \) with \( a \in \mathbb{N} \) and \( c' \) primitive. Then it is immediate that \( M^+_c(X) = M^+_c(X) \), and we may apply (4.3) to \( M^+_c(X) \) to derive (4.3) for \( M^+_c(X) \) with \( \mathfrak{E}^+(c) = \mathfrak{E}^+(c') \). This establishes (4.3) in all cases. In passing we mention that (4.27) holds also in the case where \( c \) is not primitive, as one finds from (4.21).

All other conclusions concerning \( M^+_c(X) \) in Theorem 4.1 are also available. By Lemmas 4.2 and 4.3 we see that \( \mathfrak{E}^+(c) \) is real and non-negative. Moreover, whenever (4.4) has
non-trivial solutions in $\mathbb{Q}_p$ for all primes $p$, and a solution in positive real numbers, then the $c_j$ cannot all be of the same sign, and Lemmas 4.2 and 4.3 show $E^+(c) > 0$. Finally, if (4.4) fails to have non-trivial solutions in some $\mathbb{Q}_p$, or in positive reals, then in particular there are no solutions of (4.4) in natural numbers. Hence $M^+_c(X) = 0$, which is compatible with (4.3) only when $E^+(c) = 0$. This completes the proof of Theorem 4.1 for $M^+_c(X)$.

4.4. The proof of Theorem 4.1 completed. It remains to establish Theorem 4.1 for $M_c(X)$. When $d$ is even, an inspection of the definitions of $M_c(X)$ and $M^+_c(X)$ reveals that $M_c(X) = 2^{k_s}M^+_c(X)$, and all conclusions concerning $M_c(X)$ follow from those for $M^+_c(X)$ if we put $E(c) = 2^{k_s}E^+(c)$.

When $d$ is odd, a similar but more elaborate argument applies. Since $-1$ is a $d$-th power, we have

\[(4.28)\quad M_c(X) = 2^k \sum_{\eta \in \{1,-1\}} \sum_{1 \leq j \leq s} M^+_{\eta c}(X)\]

where $\eta c = (\eta_1 c_1, \ldots, \eta_s c_s)$ is the coordinate product. Since $-1$ is also a $d$-th power residue, modulo $q$, it follows from (3.3) that $S(q,-a) = S(q,a)$, and consequently, via (4.6), one readily confirms that $E(\eta c) = E(c)$ for all $\eta$ that occur in the sum (4.28).

With the asymptotic formula (4.3) already in hand, the cognate expansion (4.2) with

\[E(c) = 2^k \mathcal{E}(c) \sum_{\eta \in \{1,-1\}} \sum_{1 \leq j \leq s} \mathcal{J}^+(\eta c)\]

is immediate consequence of (4.28). We also see that $\mathcal{E}(c)$ is real and non-negative. We already showed that $\mathcal{E}(c) > 0$ holds whenever (4.4) has non-trivial $p$-adic solutions for all primes $p$. Further, since $d$ is now odd, the equation (4.4) has a real solution with all $y_j$ non-zero. For this solution, put $y_j = y_j/|y_j|$. The analogue of (4.4) with $\eta c$ in place of $c$ has the solution $(|y_1|, \ldots, |y_s|)$, whence Lemma 4.3 yields $\mathcal{J}^+(c) > 0$. We conclude that $\mathcal{E}(c) > 0$ holds whenever (4.4) has non-trivial solutions in all $\mathbb{Q}_p$. If that fails, then (4.2) implies $\mathcal{E}(c) = 0$. The proof of Theorem 4.1 is now complete.

We remark that $\mathcal{E}(c)$ can be written in a form that is independent of the parity of $d$. In fact, if $d$ is odd, one deduces from (3.8) that

\[(4.29)\quad \mathcal{J}(c) = \int_{-\infty}^{\infty} \int_{[0,1]^{k_s}} e(\beta(c_1 t_1)^d + \ldots + c_s \langle t_s \rangle^d)) \, dt \, d\beta.

Note that $\mathcal{J}(c)$ is also defined when $d$ is even, and in this case, an inspection of (3.8) and (4.29) show that $2^{k_s} \mathcal{J}^+(c) = \mathcal{J}(c)$.

4.5. Primitive solutions. In this section, we study the equation (4.1) in “transposed” form. Note that $M_c(X)$ equals the number of solutions of

\[(4.30)\quad \sum_{j=1}^s c_j (x_{1,j} x_{2,j} \cdots x_{k,j})^d = 0\]
with \( 1 \leq |x_{i,j}| \leq X_i \) for \( 1 \leq i \leq k, 1 \leq j \leq s \). We require an asymptotic formula for the number \( M^*_c(X) \) of those solutions counted by \( M_c(X) \) that satisfy the additional constraints

\[
(x_{i,1}; x_{i,2}; \ldots; x_{i,s}) = 1 \quad (1 \leq i \leq k).
\]

With this in view, one may arrange the solutions of (4.31) according to the values of

\[
l_i = (x_{i,1}; x_{i,2}; \ldots; x_{i,s}) \text{ to infer that}
\]

\[
M_c(X) = \sum_{l \leq X} M^*_c(X_1/l_1, \ldots, X_k/l_k).
\]

By one of Möbius’ inversion formulae, we deduce that

\[
M^*_c(X) = \sum_{l \leq X} \mu(l) M_c(X_1/l_1, \ldots, X_k/l_k)
\]

where in the interest of brevity we put \( \mu(l) = \mu(l_1)\mu(l_2)\cdots\mu(l_k) \). We now suppose that the hypotheses in Theorem 1.1 hold, and inject the asymptotic formula (4.2) into the preceding identity. This yields

\[
M^*_c(X) = \mathcal{E}(c)(X)^{s-d} \sum_{l \leq X} \frac{\mu(l)}{(l)^{s-d}} + O((X)^{s-d}(\min X_i)^{-\delta/2}|c|^{s+k}),
\]

as one readily confirms. Routine estimates also show

\[
\sum_{l \leq X} \frac{\mu(l)}{(l)^{s-d}} = \zeta(s-d)^{-k} + O((\min X_i)^{-1}),
\]

so that we may conclude as follows.

**Lemma 4.4.** Let \( s > n_0(d) \). Then there is a positive number \( \delta' \) such that whenever \( c_j \in \mathbb{Z} \setminus \{0\} \) one has

\[
M^*_c(X) = \zeta(s-d)^{-k}\mathcal{E}(c)(X)^{s-d} + O((X)^{s-d}(\min X_i)^{-\delta'}|c|^{s+k}).
\]

5. **Synthesis**

The scene is prepared for a swift derivation of Theorem 1.1. The starting point is (1.9), and the strategy is to show that the function \( \theta(m) \) is part of a suitable family for Theorem 2.1 to deliver Theorem 1.1. From now on, we consider \( a = (a_0, \ldots, a_s) \) as fixed, once and for all, and suppose that the hypotheses of Theorem 1.1 are satisfied.

We begin by observing that the equations (1.1) and (4.31) become identical if one takes \( s = n + 1 \) and \( c_j = a_{j-1} \). An examination of the definition of \( \theta(m) \) and (1.10) now reveals that \( \Theta(X) = M^*_c(X) \). Hence, by Lemma 4.4 there is a positive \( \delta \) such that

\[
\Theta(X) = \zeta(n+1-d)^{-k}\mathcal{E}(a)(X)^{n+1-d} + O((X)^{n+1-d}(\min X_i)^{-\delta})
\]

holds, and we conclude that \( \theta \) obeys condition (I) with

\[
c = \zeta(n+1-d)^{-k}\mathcal{E}(a).
\]

Next, we check condition (II). Fix \( r \) with \( 1 \leq r \leq k-1 \) and put \( l = k-r \). With \( u \in \mathbb{N}^r \) and \( V \in [1,\infty]^l \), we have to evaluate the sum

\[
\Theta_u(V) = \sum_{v \leq V} \theta(u, v).
\]
Further, there are now more that $O(n^{d/2})$ elements where

$$\sum_{j=0}^{n} c_j(y_{1,j} \ldots y_{r,j} z_{1,j} \ldots z_{l,j})^d = 0$$

and observe that $\theta(u, v)$ is the number of its solutions in primitive vectors $y_i, z_i \in \mathbb{Z}^{n+1}$ with non-zero coordinates and $|y_i| = u_i, |z_i| = v_i$ (1 $\leq i \leq r, 1 \leq i' \leq l$). For a fixed permissible choice of $y_1, \ldots, y_r$ we may sum over $v \leq V$. One then obtains a quantity examined in Lemma [4.4] but with $l$ in place of $k$, with $s = n + 1$ and $c = c(y_1, \ldots, y_r)$ given by

$$c_{j+1} = a_j(y_{1,j} \ldots y_{r,j})^d \quad (0 \leq j \leq n).$$

Consequently, on writing

$$\mathcal{Y}(u) = \{(y_1, \ldots, y_r) : y_i \in \mathbb{Z}^{n+1} \text{ primitive, } |y_i| = u_i (1 \leq i \leq r)\},$$

we find that

$$\Theta_u(V) = \sum_{(y_1, \ldots, y_r) \in \mathcal{Y}(u)} M^*_c(y_1, \ldots, y_r)(V).$$

By Lemma [4.4] we now infer that

$$\Theta_u(V) = \zeta(n + 1 - d)^{-k}(V)^{n+1-d} \sum_{(y_1, \ldots, y_r) \in \mathcal{Y}(u)} \mathcal{E}(c(y_1, \ldots, y_r)) + E$$

where

$$E \ll \langle V \rangle^{n+1-d}(\min V_i)^{-\delta} \sum_{(y_1, \ldots, y_r) \in \mathcal{Y}(u)} |c(y_1, \ldots, y_r)|^{n+1+k}.$$

Note that $|y_{1,j} \ldots y_{r,j}| \leq |y_1| \cdots |y_r| = \langle u \rangle$. This yields

$$|c(y_1, \ldots, y_r)| \ll \langle u \rangle^d.$$

Further, there are now more that $O((u)^{nr})$ elements in $\mathcal{Y}(u)$. It follows that

$$E \ll \langle V \rangle^{n+1-d}(\min V_i)^{-\delta}(u)^{nr+d(n+1+k)} \ll \langle V \rangle^{n+1-d}(\min V_i)^{-\delta}|u|^D$$

where $D = r(nr + d(n + 1 + k))$. By [5.2], [5.3] and [5.4], we see that $\theta$ satisfies condition (II).

For condition (III), we note that $\theta_\sigma = \theta$ holds for all $\sigma \in S_k$ by symmetry, as one confirms from (1.1). We have now proved that the function $\theta$ alone is a $(n+1-d, c, D, 1, \delta)$-family where $c$ and $D$ are as above, and $\delta$ is a sufficiently small positive number. We may now apply Theorem [4.4] with $N = B^{1/(n+1-d)}$. Then, whenever $c > 0$, the conclusions of Theorem [1.1] follow from (1.9), and by (5.3) we also see that the constant $C$ is given by

$$C = \frac{\mathcal{E}(a) \mathcal{G}(a)}{2^k(k-1)! \zeta(n+1-d)^k}.$$
