Supplement Figure 2: Antibody validation by comparison of antibodies. The panels show a complete concordance of staining results obtained by two independent TROP2 antibodies. Using MSVA-733R, the stainings show a predominantly membranous staining of epithelial cells from the endometrium (A) and the fallopian tube (B) as well as of a limited number of follicles in the thyroid (C) and few selected cells of the adenohypophysis (D). Using clone AF650, nearly identical stainings are seen in endometrium (E), fallopian tube (F), thyroid (G), and the adenohypophysis (H). The images A-D and E-H were taken from consecutive tissue sections. Due to the polyclonal nature of AF650, background staining is slightly higher than seen for MSVA-733R.
