**ABSTRACT** Chloroplast DNA sequences are a versatile tool for species identification and phylogenetic reconstruction of land plants. Different chloroplast loci have been utilized for phylogenetic classification of plant species. However, there is no report for a short DNA sequence that can distinguish all plant species from each other. Molecular markers derived from the complete chloroplast genome can provide effective tools for species identification and phylogenetic resolution. Thus, the complete chloroplast genome sequence of Korean landrace “Subicho” pepper (*Capsicum annuum* var. *annuum*) has been determined here. The total length of the chloroplast genome is 156,878 bp, with 37.7% overall GC content. A pair of IRs (inverted repeats) of 25,801 bp was separated by a small single copy (SSC) region of 17,929 bp and a large single copy (LSC) region of 87,347 bp. The chloroplast genome harbors 132 known genes, including 87 protein-coding genes, 8 ribosomal RNA genes, and 37 tRNA genes. A total of seven of these genes are duplicated in the inverted repeat regions, nine genes and six tRNA genes contain one intron, while two genes and a *ycf* have two introns. Analysis revealed 144 simple sequence repeat (SSR) loci and 96 variants, mostly located in the intergenic regions. The types and abundances of repeat units in Capsicum species were relatively conserved and these loci will be useful for developing *C. annuum* cp genome vectors.

**Keywords** *Capsicum annuum*, Chloroplast, DNA sequencing, Subicho pepper

**INTRODUCTION**

Chloroplasts are the large organelles responsible for photosynthesis that converts CO₂ into carbohydrates. It is widely agreed that chloroplast was derived from a single ancestral cyanobacterium into the ancestral plant by one symbiogenetic event (Gray 1999). The chloroplast is unusual in containing its own genetic system, which replicates by division. DNA fragments of the chloroplast genome have been widely used for phylogenetic reconstruction and species-level identification in land plants (Dong *et al*. 2012; Dong *et al*. 2015; Hollingsworth *et al*. 2011; Group *et al*. 2009). Because the chloroplast genome has a simple and stable genetic structure, there are no or rare recombinations, and universal primers have been used to amplify target sequences. In general, the chloroplast gene structure in angiosperms is conserved, with inverted repeat (IR) regions separated by small (SSC) and large (LSC) single copy regions (Palmer 1991).

*Capsicum* L. (pepper) is a member of the Solanaceae family and comprises about 32 recognized species (Moscone *et al*. 2007). *Capsicum* originated in the New World and is cultivated in temperate and tropical regions (Eshbaugh 1993; Pozzobon *et al*. 2005). The exact nature of when, where, and how the process of *Capsicum* domestication occurred is unknown. *Capsicum annuum* var. *annuum*, is a unique *Capsicum* species known as the aji Amarillo chilli or Peruvian hot pepper and is well-known as “Subicho” in Korea for its rich variation in flavors and aromas. Pepper has important roles in various aspects of the economy, in food and in pharmaceutics (Kumar *et al*. 2006). Therefore, knowledge of the genetic diversity among the germplasm is
vital for strategic germplasm collection, maintenance, conservation and utilization. Molecular methods based on DNA sequence analysis provide useful information for taxonomy, species identification, and phylogenetics. In the last few decades molecular phylogenetics has rapidly developed, and is gaining increasing importance in resolving phylogenetic relationships.

Currently, the interspecies relationships within the genus Capsicum remain highly controversial. Molecular phylogenetic research on Capsicum has been extensively carried, but there is no apparent structure to reveal the true phylogenetic relationships between its species. The major reason for the lack of phylogenetic structure is because the genus Capsicum contains a wide variety of species. In addition, the lack of appropriate DNA sequences greatly limits the ability to perform adequate molecular phylogenetic research on Capsicum. Most of the phylogenetic studies performed to date have limited on availability of suitable DNA sequences. Consequently, achieving phylogenetic resolution and performing species identification have been almost impossible. Two chloroplast genome sequences from Capsicum species, the American bird pepper (Capsicum annuum var. glabriusculum) (Zeng et al. 2014) and cultivated pepper (Capsicum annuum L.) (Jo et al. 2011), were reported previously. The complete chloroplast genome sequence of the Korean landrace “Subicho” pepper Capsicum annuum var. annuum reported here enriches the gene information for C. annuum var. annuum and contributes to further study of population, phylogenetic and cp genetic engineering of this species.

MATERIALS AND METHODS

Sampling and DNA extraction

Subicho seeds (Accession No. IT216436) were collected from the National Agrobiodiversity Center, Rural Development Administration, Republic of Korea. Seeds were germinated and grown in a greenhouse, and fresh leaves were collected from 40-day-old seedlings, and DNA was extracted to construct cp DNA libraries.

Library preparation and sequencing

An Illumina paired-end cp DNA library (average insert size of 500 bp) was constructed using the Illumina TruSeq library preparation kit following the manufacturer’s instructions. The libraries were sequenced with 2 x 300 bp on the MiSeq instrument at LabGenomics (http://www.lab.genomics.com/kor/).

Chloroplast genome assembly

Prior to cp de novo assembly, low quality sequences (quality score < 20; Q20) were filtered out, and the remaining high quality reads were assembled using the CLC Genome Assembler (version beta 4.6, CLC Inc. Aarhus, Denmark) with a 200-600-bp overlap size. Cp contigs were selected from the initial assembly by performing a BLAST (ver. 2.2.31) search against known cp sequences. The selected contigs were oriented to construct the complete cp genome structure. Ambiguous nucleotides or gaps were corrected manually to build the complete cp genome.

Gene annotation

The web-based program Dual OrganellarGenoMe Annotator (DOGMA, http://dogma.ccbb.utexas.edu/) was used to annotate the assembled genome using default parameters to predict protein coding, tRNA and rRNA genes. Subsequently, BLASTN (ver. 2.2.31) was used to further identify intron-containing gene positions by searching a published cp genome database (GenBank accession NC_018552; Jo et al. 2011). A cp gene map was constructed using the OrganellarGenomeDRAW software (OGDRAW, http://ogdraw.mpimp-golm.mpg.de).

Discovery of SNPs and SSRs

Sputnik (http://espressosoftware.com/pages/sputnik.jsp) software was used to find the SSR markers present in the cp genome of C. annuum var. annuum. It uses a recursive algorithm to search for repeats with length between 2 and 5, and finds perfect, compound and imperfect repeats. Sputnik has been applied for SSR identification in many species including Arabidopsis and barley (Cardle et al. 2000). To identify SNP and INDEL variants in C. annuum var. annuum cp genome, we used BWA (Li and Durbin 2009).
RESULTS

Chloroplast genome assembly

We sequenced the cp genome of Korean landrace “Subicho” pepper *C. annuum* var. *annuum* using the Illumina genome analyzer platform. Illumina paired-end (2 × 300 bp) sequencing produced a total of 7,100,754 paired-end reads, with an average fragment length of 256 bp, which were then analyzed to generate 1,536,526,037 bp of sequence. Low quality reads (Q20) were filtered out, and the remaining high quality reads were mapped to the reference cp genome of *C. annuum* L. (GenBank accession...

**Table 1. General features of the *C. annuum* var. *annuum* chloroplast genome**

| Features                          | Chloroplast |
|-----------------------------------|-------------|
| Genomic size (bp)                 | 156,878     |
| GC content (%)                    | 37.7        |
| Total number of genes             | 132         |
| Protein coding genes              | 87          |
| No. of rRNA genes                 | 8           |
| No. of tRNA genes                 | 37          |
| No. of gene duplicated in IR regions | 7   |
| Total introns                     | 12          |
| Single intron (gene)              | 9           |
| Double introns (gene)             | 3           |
| Single intron (tRNA)              | 6           |

**Features of the chloroplast genome**

The chloroplast genome of Korean landrace “Subicho” pepper *C. annuum* var. *annuum* reported here has a total length of 156,878 bp (Figure 1) and is composed of a LSC region of 87,347 bp, two IR copies (IRA and IRB) totalling 25,801 bp and a SSC region of 17,929 bp. The whole chloroplast genome of “Subicho” pepper *C. annuum* var. *annuum* was 97 bp longer than the reported *C. annuum* L. chloroplast genome (GenBank accession NC_018552) and 266 bp longer than the *C. annuum* var. *glabriusculum* chloroplast genome (GenBank accession KJ619462). Also, the SSC and IR regions of *C. annuum* var. *annuum* were 80 and 78 bp longer, respectively, and its LSC region was 19 and 131 bp, respectively, shorter than the previously reported chloroplast genomes. The overall GC content of the chloroplast genome was 37.7%, and in the LSC, SSC and IR regions it was 35.7%, 31.9%, and 43.0%, respectively. The chloroplast genome includes 132 unique genes, composed of 87 protein-coding genes, 37 tRNA genes and 8 rRNA genes (Table 1). A total of seven of these genes are duplicated in the inverted repeat regions, nine genes and six tRNA genes contain one intron, while two genes (*clpP* and *rps12*) and a *ycf* (*ycf3*) have two introns.

**Discovery of SSRs and SNPs**

A total of 144 potential SSRs motifs were identified which are located only in the intergenic region (Table S1), and the majority belonged to tetra-nucleotide (50%) and penta-nucleotide (21.5%) repeats. All other types of SSRs such as di and tri nucleotide motifs were relatively low (28.5%), and the majority of tetra-nucleotide SSRs had the ATAA/TAAA/AAAT motif, followed by those with the AAAT/AATA/ATAA motif, and the remaining those with the TTTG/TTGT/TGTT, TCTT/CTTT/TTTC, and AATT/ATTA/TATAA motifs were found with similar proportion (6.25%). Three different repeats those with the ATATT/TATT/TATT, TTTTA/TTTAT/TTATT, and TTTT/TTTT/TTTT motifs were identified among penta-nucleotide SSRs. The TTC/TCT/CTT and TTA/TAT/ATT motifs were identified among the tri-nucleotide SSRs. Only, the TA/AT motif was identified as the dinucleotide SSRs (Table S1). Comparison of *C. annuum* var. *annuum* cp genome sequence with the reference cp sequence of *C. annuum* revealed a total of 96 mutations (45 SNPs and 51 InDels) and 46 of these variants involving more than one nucleotide (Table S2 and S3). Amongst the detected variants, 13 SNPs and 3 InDels were observed in the coding region of the cp genome. Amongst these SNPs and InDels, there were 78, 17 and 1 mutations located in LSC, SSC, and IRa region, respectively.
DISCUSSION

Here we report the re-sequencing and assembly of a cp genome using the Illumina sequencing platform in which we recovered five contigs comprising 156,878 bp covering the entire *C. annuum* var. *annuum* cp genome. Reported *Capsicum* cp genomes range in size from 156,612 to 156,781 bp, and the size of the *C. annuum* var. *annuum* cp genome identified here is consistent with those reported previously in plants of the same species (Zeng et al. 2014; Jo et al. 2011). The entire cp genome of *C. annuum* var. *annuum* was 97 bp longer than the reported *C. annuum* L. cp genome (GenBank accession NC_018552) and 266 bp longer than *C. annuum* var. *glabriusculum* cp genome (GenBank accession KJ619462). Also, the SSC and IR regions of *C. annuum* var. *annuum* were 80 and 77 bp longer, respectively, and the LSC region was 19 bp and 33 bp shorter, respectively, than those of the previously reported cp genomes.

The average GC content in the *C. annuum* cp genome is 37.7%, similar to other capsicum species. The data generated using the Illumina platform covered a greater depth (128 ×) of the cp genome whereas, in the previous studies cp genome sequence coverage was not reported and were able to resolve the ambiguities present in the GS-FLX pyrosequencing. Thus, the data from the cp assembly reported here supports previous findings that Illumina can produce high quality sequence assemblies covering a greater genome depth (Wu et al. 2014). For the cp genome assembly, small reads alignment to reference genome is an alternative approach to the strategy of *de novo* assembly. The read mapping approach is computationally less demanding and faster than *de novo* assembly. Moreover, it has the advantage that the read coverage information can be used for reliable detection of sequence variation.

Cp structural rearrangements and gene loss-and-gain events often occur in some angiosperms and are especially common in monocot cp genomes. The organization and

**Table 2.** Genes present in the *C. annuum* var. *annuum* chloroplast genome.

| Gene products of *Capsicum annuum* var. *annuum* | Genes present |
|--------------------------------------------------|---------------|
| Photosystem I                                     | psaA, B, C, I, J, ycf3, ycf4 |

1) Gene containing a single intron  
2) Gene containing two introns  
3) Two gene copies in IRs  
4) Trans-splicing gene
gene order of the Capsicum cp genome exhibited the general cp genome structure of angiosperms (Sugiura 1992). The Capsicum cp genome contained 132 genes (Table 2), of which there were 8 rRNA genes, 37 tRNA genes, 21 ribosomal subunit genes (12 small subunit and 9 large subunit) and 4 DNA-directed RNA polymerase genes. Forty-six genes were involved in photosynthesis, of which 11 encoded subunits of the NADH-oxidoreductase, 7 for photosystem I, 15 for photosystem II, 6 for the cytochrome b6/f complex, and 6 for different subunits of ATP synthase and 1 for the large chain of ribulose bisphosphate carboxylase. Five genes were involved in different functions, and three genes were of unknown function. As shown in Figure 1 and Table 2, genome organization appeared to be more conserved with unique gene sequences, as discovered previously in Capsicum species (Zeng et al. 2014; Jo et al. 2011). However, in this newly determined cp genome, we found 132 predicted genes and size variations were observed in the IR and LSC regions.

A total of 144 cpSSRs markers were identified in 156.8 kb sequence of the capsicum chloroplast genome. The observed frequency of SSRs was approximately 1/1.08 kb of chloroplast genome. This was higher than the SSR frequency previously observed for the C. annuum cp genome (1/2.90 kb) (Jo et al. 2011). More interestingly, the cpSSRs were only observed in the non-coding region of the cp genome. Similarly, most of the SNPs and InDels in the cp genome present in intergenic region, and only 16 variants were located in genic region (Table S2 and S3).

CONCLUSION

Solanaceae is an important ethnobotanical family of dicots comprising more than 3,000 species and is extensively utilized by humans and has recently become a model of comparative and evolutionary genomics research. The cp genome sequences of Capsicum species have been reported previously; however, information on cp gene content is limited. Here, we report the re-sequencing and assembly of a Korean landrace “Subicho” pepper C. annuum var. annuum. The cp genome is well-conserved in terms of size, gene arrangement, and coding sequences, within major subgroups of the plant kingdom. This represents the cp genome sequence of pepper described herein is a valuable resource for studying Capsicum population, phylogenetic and cp genetic engineering of this genus.
