1Department of Otorhinolaryngology, Severance Hospital, Yonsei University College of Medicine, Seoul; 2Division of Cardiology, Severance Cardiovascular Hospital, Yonsei University College of Medicine, Seoul; 3The Airway Mucus Institute, Yonsei University College of Medicine, Seoul, Korea.

Purpose: Obstructive sleep apnea (OSA) is considered an independent risk factor for hypertension. However, it is still not clear which clinical factors are related with the presence of hypertension in OSA patients. We aimed to find different physical features and compare the sleep study results which are associated with the occurrence of hypertension in OSA patients. Materials and Methods: Medical records were retrospectively reviewed for patients diagnosed with OSA at Severance Cardiovascular Hospital between 2010 and 2013. Males with moderate to severe OSA patients were enrolled in this study. Clinical and polysomnographic features were evaluated to assess clinical variables that are significantly associated with hypertension by statistical analysis. Results: Among men with moderate to severe OSA, age was negatively correlated with hypertension (odds ratio=0.956), while neck circumference was positively correlated with the presence of hypertension (odds ratio=1.363). Among the polysomnographic results, the lowest O₂ saturation during sleep was significantly associated with the presence of hypertension (odds ratio=0.900). Conclusion: Age and neck circumference should be considered as clinically significant features, and the lowest blood O₂ saturation during sleep should be emphasized in predicting the coexistence or development of hypertension in OSA patients.

Key Words: Sleep apnea, hypertension, polysomnography, neck circumference, lowest oxygen saturation level

INTRODUCTION

Obstructive sleep apnea (OSA) is commonly associated with hypertension, and the main pathophysiologic mechanism for the blood pressure-elevating effect of OSA is the increased sympathetic activity that influences vascular resistance and cardiac output.1 Other features such as a pro-inflammatory effect, increased oxidative stress, and increased vascular stiffness are also suggested mechanisms that influence the increased risk of hypertension in OSA patients.1 Additionally, blood pressure con-
trol is critical because of its effect on cardiovascular morbidity and mortality.\textsuperscript{2,3} OSA is known as a secondary cause of hypertension but also independently associated with target-organ damage by sympathetic overactivity in patients having hypertension.\textsuperscript{4,5} Recently, the role of nocturnal rostral fluid shift in the pathogenesis of OSA has been raised and OSA can be aggravated through increase of pharyngeal resistance induced by co-existing hypertension.\textsuperscript{6,7} Therefore, early diagnosis of hypertension in OSA patients is very important.

In a previous study, patients who have hypertension or OSA were reported to have higher prevalence of diabetes mellitus, metabolic syndrome, and dyslipidemia (including low level of high density lipoprotein and high level of triglyceride).\textsuperscript{8-11} They also had distinguishing physical characteristics such as increased body mass index (BMI), neck circumference, and abdominal circumference compared to control.\textsuperscript{4} In another study, age, sex, BMI, and family history of hypertension were representatively different between OSA patients with hypertension and OSA patients having normal blood pressure.\textsuperscript{12} Although OSA is now thought to be an independent risk factor of hypertension, the characteristics associated with hypertension in patients with OSA are heterogenous and studies are still insufficient.

Many clinicians have focused on the influence of gender differences on the occurrence of hypertension in OSA patients. The Western New York Health Study reported a 66\% higher prevalence of hypertension among women with subjective symptoms but subjective symptoms were not associated with the prevalence of hypertension among male patients.\textsuperscript{13} This association was independent of socioeconomic status, traditional cardiovascular risk factors, and psychiatric comorbidities.\textsuperscript{13} In another study, age was not significantly associated with the occurrence of hypertension in patients who reported a short duration of sleep.\textsuperscript{14} Obesity, especially visceral obesity, contributes to the pathogenesis of hypertension in OSA patients.\textsuperscript{15} The results from previous reports have suggested many factors that are associated with hypertension in OSA patients. However, the conclusions are inconsistent and the association between the clinical characteristics of patients with hypertension and detailed polysomnographic data has not been reported. We aimed to find different clinical characteristics and the factors of sleep study between OSA patients who are hypertensive and OSA patients who have normal blood pressure. Lipid profile and fasting glucose level were also included in the analysis because of high prevalence of metabolic syndrome in OSA patients.\textsuperscript{15} Based on these results, we tried to suggest useful predictors that might be helpful in early diagnosis of un-identified hypertension in OSA patients.

**MATERIALS AND METHODS**

**Study population**

This study was approved by the Institutional Review Board of Yonsei University College of Medicine (IRB No. 4-2014-0132). Medical records were retrospectively reviewed for patients diagnosed with OSA based on validated, ambulatory unattended polysomnography (Embletta ×100)\textsuperscript{16} performed at Severance Hospital between 2010 and 2013. Only male patients were enrolled because the characteristics of OSA in women and results in men are more heterogenous.\textsuperscript{17} As such, for subjects with asymptomatic obstructive sleep apnea, polysomnography was performed as an etiologic and risk factor assessment in hypertensives, atrial fibrillation and in patients with coronary artery disease. Patients completed the polysomnography examination, the Epworth Sleepiness Score (ESS) questionnaire to assess daytime sleepiness and the blood tests for lipid profiles and fasting glucose level. Male patients whose apnea/hypopnea index (AHI) was more than 15 (total 183 patients) were enrolled in this study. Office blood pressure was measured twice either with a mercury sphygmomanometer or an aneroid sphygmomanometer (Welch Allyn Silver Series DS45, Skaneateles Falls, NY, USA) and the average value was used. The patients were grouped as hypertension if they are diagnosed hypertension based on blood pressure following current guidelines published by the European Society of Hypertension\textsuperscript{18} or they are currently taking blood pressure lowering medications. The patients who do not belong to above category were grouped as non-hypertensives. Other past medical histories of enrolled patients were not considered in our study. Participants were excluded if they had sleep studies with un-interpretable measurements, inadequate sleep duration, missed physical measurements or lack of any laboratory result.

**Anthropometric measurements**

Anthropometric characteristics were measured by one skilled examiner according to standardized methods. Height was measured without shoes from the top of the head to the end of the first toe. Neck circumference (NC) was measured using a flexible ruler at the thyroid cartilage level. Waist circumference was measured at the midway point between the lowest portion of the rib cage and the iliac crest. Hip circumference
was measured at the largest lateral extension of the hips.

**Blood analysis**

Blood samples were obtained after an overnight fast. Lipid profiles including total cholesterol, triglycerides (TG), high density lipoprotein (HDL), and low density lipoprotein (LDL) as well as fasting blood glucose level were measured.

**Statistics**

The study population was divided into OSA patients without hypertension (non-HTN group; n=67) and OSA patients with hypertension (HTN group; n=116). For the comparison of continuous variables by group, two independent sample t-tests were used. Univariate and multivariate logistic regression analyses were applied to calculate the odds ratios (OR) of variables. All variables with a \( p < 0.05 \) in the univariate analysis were selected and further studied by multivariate logistic regression analysis. Adjusted OR with 95% confidence intervals were calculated for these independent variables. Pearson correlation coefficients were calculated between variables and polysomnographic findings. All analyses were done using SPSS version 20 (IBM Corporation, Armonk, NY, USA).

## RESULTS

**Differences in physical parameters and blood tests: non-HTN vs. HTN group**

A total of 183 moderate to severe male OSA patients were analyzed in this study. The mean ages were 60.70±9.27 years for the non-HTN group and 53.26±12.73 years for the HTN group \((p<0.001)\). HTN group patients were more obese, which was represented by increased body weight and high level of BMI. BMI was 25.18±3.04 in non-HTN group and 27.12±3.55 in HTN group \((p<0.001)\). Neck circumference was 38.45±2.19 cm in non-HTN group and 40.27±2.71 cm in HTN group showing meaningful difference \((p<0.001)\). Central obesity-related physical factors such as waist (93.08±8.58 cm in non-HTN group and 96.86±8.83 cm in HTN group) and hip circumferences (97.87±6.41 cm in non-HTN group and 103.02±10.33 cm in HTN group) were also significantly different between two groups \((p<0.001)\).

The basal blood laboratory tests revealed that the TG level was the only different factor which was 127.17±73.31 mg/dL in non-HTN group and 167.26±123.81 mg/dL in HTN group (Table 1). The HDL, LDL and fasting glucose level were not significantly different.

Age, weight, NC, waist and hip circumferences, and TG levels \((p<0.05)\) which were statistically different between the non-HTN and HTN groups were selected and further evaluated by univariate and multivariate logistic regression analysis (Table 2). Age was negatively (OR=0.956) and NC was positively (OR=1.363) related to the presence of hypertension, and these clinical characteristics were also significant in multivariate analysis \((p<0.05)\) (Fig. 1).

**Differences in polysomnographic parameters: non-HTN vs. HTN group**

Typically, the AHI is considered diagnostic for OSA. We

considered other features, including the longest apnea/hypopnea duration, average O\textsubscript{2} saturation, and lowest O\textsubscript{2} saturation and these were evaluated according to the presence of hypertension (Table 3). The average O\textsubscript{2} (94.96±1.27% in non-HTN, 94.27±1.91% in HTN) and lowest O\textsubscript{2} saturation levels (84.15±4.97% in non-HTN, 80.58±6.52% in HTN) were significant factors influencing the presence of hypertension by the t-test. Mean AHI was also significantly different between two groups (29.79±11.35 in non-HTN, 34.12±16.89 in HTN). These factors were further studied by univariate and multivariate analysis, and the lowest O\textsubscript{2} saturation level was the only significant factor identified in multivariate analysis ($p=0.006$). The OR for the lowest O\textsubscript{2} saturation was 0.900, which means that as the lowest O\textsubscript{2} saturation level increases, the probability of co-existing hypertension decreases (Table 4, Fig. 2). Other factors of sleep study were not statistically meaningful in multivariate analysis. Excessive daytime sleepiness assessed by ESS was also not a meaningful factor. To further study the clinical significance of the lowest O\textsubscript{2} saturation level during sleep, patients were grouped, and the correlation of clinical variables and the lowest O\textsubscript{2} saturation level were compared (Table 5). In the HTN group, NC, BMI, and waist circumference, were negatively correlated with the lowest O\textsubscript{2} saturation level ($p<0.05$); these correlations were not demonstrated in the non-HTN group. NC and waist circumference had the highest correlation coefficient in the HTN group ($r=-0.276$). Age was correlated with the lowest O\textsubscript{2} saturation level among all patients ($r=0.159$, $p=0.032$). However, age did not show any significant correlation with the lowest O\textsubscript{2} saturation level in subgroup analysis for the HTN and non-HTN groups.

**DISCUSSION**

Growing evidence suggests that OSA is one of the major causes of hypertension.\textsuperscript{19,20} In our study of 183 men with moderate to severe OSA, 116 men had hypertension (63% prevalence). Recently, it was reported that portable devices showed good diagnostic performance compared with level 1 sleep tests in adult patients\textsuperscript{21} and our result also shows that Embletta ×100 which is a level 2 portable device is useful in diagnosis of OSA. The prevalence of hypertension in OSA patients was higher compared to previous reports.\textsuperscript{22} This may be because most of the hypertensive patients referred to Severance Hospital have severe hypertension and are often difficult to treat. Furthermore, the exclusion of mild OSA may have influenced this prevalence.

In this study, age was the most meaningful factor that predicted the co-existence of hypertension in OSA patients. Interestingly, the mean age was 7 years younger in the HTN group compared to the non-HTN group. Similar results were previously reported and the OR of hypertension decreased as age increased in severe OSA patients.\textsuperscript{23} However, increased age has been positively associated with sleep-disordered breathing,\textsuperscript{24} and a contradictory study reported that age had no significant association with hypertension in male OSA patients.\textsuperscript{13} Based on our study, middle-aged patients with an AHI $>15$ should be carefully evaluated for concurrent hypertension. However, care should be taken
AHI, apnea/hypopnea index; ESS, epworth sleepiness score; REM AHI, apnea/hypopnea index in rapid eye movement sleep; NREM AHI, apnea/hypopnea index in non rapid eye movement sleep; OSA, obstructive sleep apnea; HTN, hypertension.

Table 3. Multiple Variables of Polysomnography in Moderate to Severe OSA Patients with or without Hypertension

| Variable                        | No HTN (n=67) | HTN (n=116) | p value |
|---------------------------------|---------------|-------------|---------|
| Longest apnea duration (s)      | 45.91±18.52   | 44.79±18.50 | 0.694   |
| Longest hypopnea duration (s)   | 58.81±17.51   | 60.38±20.42 | 0.598   |
| REM AHI (events/hr)             | 25.52±18.87   | 29.97±20.05 | 0.146   |
| NREM AHI (events/hr)            | 31.83±22.12   | 35.35±22.52 | 0.195   |
| Average O₂ saturation (%)       | 94.96±1.27    | 94.27±1.91  | 0.009   |
| Lowest O₂ saturation (%)        | 84.15±4.97    | 80.58±6.52  | <0.001  |

when interpreting these results as there is the potential for selection bias in this study. When the average BMI of younger (age <60 yr) and older patients (age ≥60 yr) were compared, younger patients had higher BMI levels compared to the older patients, which might explain why age was negatively correlated with hypertension.

The prevalence of obesity in the general population is increasing and becoming a significant health burden. In this study, several physical measures such as body weight, NC, waist, and hip circumferences were significantly higher among patients with hypertension. Although obesity and OSA are independently associated with hypertension, studies show they are interrelated. Obesity is an important risk factor for both hypertension and OSA.²⁵-²⁸ In our study, BMI in the HTN group was significantly higher than in the non-HTN group. When we defined obesity as BMI above 25, obese patients had much higher value of NC, suggesting the relation of obesity with neck circumference (data not shown). NC, one clinical characteristics related to higher mortality of acute ischemic stroke, has been shown to be an independent predictor of coronary artery disease.²⁹,³⁰ NC was identified in our study as a significant clinical characteristic by multivariate regression analysis and was associated with the presence of hypertension in moderate to severe OSA patients. In recent studies, rostral fluid displacement in hypertensive patients has been linked to OSA by contributing to the narrowing of the upper airway,³¹,³² and NC could be increased by this fluid shift from the lower body.²²,²⁹,³⁰,³³,³⁴ This result suggests that NC should not be overlooked in evaluating OSA patients. Furthermore, when we plotted Receiver Operating Characteristic (ROC) Curve of NC to the presence of HTN, the value of the Area Under the ROC Curve was 0.693 and the cut-off value was 39.750 (data not shown). We suggest that the patients whose NC is more than 39.75 have increased risk for the presence of concurrent HTN.

Lipid profile and fasting glucose level were not associated with the presence of hypertension. Subjective daytime sleepiness estimated by the ESS was not associated with the incidence of hypertension, while one study reported that prescreening of OSA by ESS was useful in predicting post-cardiac operative atrial fibrillation.³⁵ AHI defines only the number of apneic or hypopneic events per hour. Diagnosis of OSA is based on AHI and
other features reflecting the oxidative condition during sleep and should be considered as critical values in predicting co-existing hypertension. AHI is traditionally an important factor in the diagnosis of OSA, but it does not reflect the total apnea/hypopnea duration or O2 desaturation. Thus, comprehensive evaluation of polysomnographic data including AHIs, apnea/hypopnea duration, and O2 desaturation level during sleep should be performed.

In this study, many factors of clinical and sleep study were different between non-HTN and HTN group in OSA patients. Among them, NC and lowest O2 saturation were meaningful factors by multivariate test and we suggest that these should be considered in OSA patients. This result should allow the clinician to better predict which patients with OSA are at higher risk for complications.

ACKNOWLEDGEMENTS

We are very thankful for Jae Hee Kim and the other researchers at the Cardiology laboratory for helping with data collection.
