On the complete integrability and linearization of nonlinear ordinary differential equations - Part II: Third order equations

By V. K. Chandrasekar, M. Senthilvelan and M. Lakshmanan
Centre for Nonlinear Dynamics, Department of Physics, Bharathidasan University, Tiruchirapalli - 620 024, India

We introduce a method for finding general solutions of third-order nonlinear differential equations by extending the modified Prelle-Singer method. We describe a procedure to deduce all the integrals of motion associated with the given equation so that the general solution follows straightforwardly from these integrals. The method is illustrated with several examples. Further, we propose a powerful method of identifying linearizing transformations. The proposed method not only unifies all the known linearizing transformations systematically but also introduces a new and generalized linearizing transformation (GLT). In addition to the above, we provide an algorithm to invert the nonlocal linearizing transformation. Through this procedure the general solution for the original nonlinear equation can be obtained from the solution of the linear ordinary differential equation.

Keywords: Integrability, Integrating factor, Linearization, Equivalence problem

1. Introduction

In a previous paper (Chandrasekar et al. 2005) we have discussed the complete integrability aspects of a class of second-order nonlinear ordinary differential equations (ODEs) through a nontrivial extension of the so called Prelle-Singer (PS) (Prelle & Singer 1983; Duarte et al. 2001) procedure. We have illustrated the procedure with several physically interesting nonlinear oscillator examples. We have also developed a straightforward algorithmic way to transform the given second order nonlinear ODE to a linear free particle equation, if it is linearizable.

One of the questions raised at the final stage of our earlier work (Chandrasekar et al. 2005) was that what are the implications of the novel features which we introduced in the extended Prelle-Singer procedure to obtain the second constant of motion (in the case of second order ODEs) to third and higher order ODEs. To have a closer look at the problem let us recall our earlier work briefly here. We considered a second order ODE of the form $\frac{d^2 x}{dt^2} = \frac{P(t,x,\dot{x})}{Q(t,x,\dot{x})}$, $P, Q \in \mathbb{C}[t,x,\dot{x}]$, and explored two pairs of independent functions, say, $R_i$ and $S_i$, $i = 1, 2$, associated with the underlying ODE. These functions are nothing but the integrating factors and null forms, respectively. Once these two pairs of functions are determined (by
solving an overdetermined system of first order PDEs) then each pair leads to an independent integral of motion, which can then be used to find the general solution for the given equation. Thus instead of integrating the first integral and obtaining the general solution which is conventionally followed in the literature we implemented some novel ideas in the PS method such that one can construct the general solution for the given equation in a self contained way and, in fact, our procedure works for a class of problems.

In the case of third order ODEs, one should have three independent integrals of motion in order to establish the complete integrability. To deduce these three integrals one should have three pairs of independent functions \((R_i, U_i, S_i)\), \(i = 1, 2, 3\). When we extend the PS procedure to third order ODEs we find that the determining equations for the integrating factors and null forms provide either one or two integrals of motion only straightforwardly. Again the hidden form of the functions \((R_3, U_3, S_3)\) should be explored in order establish the complete integrability of the given equation within the frame work of PS procedure. In this paper we describe a procedure to capture the required set of functions. With the completion of this task we formulate a simple, straightforward and powerful method to solve a wide class of third order ODEs of contemporary literature.

We stress at this point that the application of PS procedure to third order ODEs is not a straightforward extension of the second order case. In fact one has to overcome many faceted problems. The first and foremost one is how to solve the determining equations in such a way that one could obtain three sets of independent functions, namely, \((R_i, U_i, S_i)\), \(i = 1, 2, 3\), in a systematic way. In the present case we have six equations for three unknown functions (in the case of second order equations we have three equations for two unknowns). We overcome this problem by adopting suitable methodologies, the details which we present in §3. Another obstacle one could face in higher order ODEs, at least in some cases, is that one may be able to get only one integral of motion and in this situation how one would be able to generate the remaining integrals of motion from the first integral is also tackled by us in this paper.

Our main goal, besides the above, is to bring out a novel and straightforward way to construct linearizing transformations for third order ODEs. The latter can be used to transform the given third order nonlinear ODEs to a linear equation. We note that unlike the second order equations, the third order ODEs can be linearized through different kinds of transformations, namely, invertible point transformation (Ibragimov & Meleshko 2005), contact transformation (Bocharov et al. 1993; Ibragimov & Meleshko 2005) and generalised Sundman transformation (Berkovich & Orlova 2000; Euler et al. 2003; Euler & Euler 2004).

In this paper we introduce a new kind of transformation which can be effectively used to linearize a class of nonlinear third order ODEs. In fact, one can linearize certain equations only through this transformation alone and not by the known ones in the literature. We call this transformation as generalized linearizing transformation (GLT). We note that generalised Sundman transformation is a special case of this transformation. In the generalised Sundman transformation the new independent variable is a nonlocal one and so even though one is able to transform the given nonlinear third order ODE to a linear one due to the nature of nonlocal independent variable it is not easy to write down the general solution. In the case of generalised linearizing transformation both the new dependent and independent
Integrability and Linearization

variables contain derivative terms also in addition to the independent variable being nonlocal. Even for this general case, in this paper, we succeed to present an efficient algorithm to deduce the general solution.

Another fundamental problem regarding linearization is how to deduce the linearizing transformations systematically. Generally, Lie symmetry analysis and direct methods are often used to deduce the point and contact transformations (Steeb 1993; Olver 1995; Bocharov et al. 1993; Bluman & Anco 2002; Ibragimov & Meleshko 2005). In this work we propose a simple and straightforward method to deduce linearizing transformations and we derive them from the first integral. Our method of deducing linearizing transformations has several salient features. Irrespective of the form of the linearizing transformation (point/contact/generalised Sundman transformation), it can be derived from the first integral itself. We also note that one can also linearize a third order ODE to the second order free particle equation through our method. An added advantage of our method is that suppose a given equation is linearizable through one or more kinds of transformations then our procedure provides all these transformations in a straightforward way and as far as our knowledge goes no such single method has been formulated in the literature.

The plan of the paper is follows. In the following section we extend the PS procedure to third order ODEs and indicate new features in finding the three independent integrals of motion. In §3, we describe the methods of solving the determining equations and how one can obtain compatible solutions from them. We illustrate the procedure with several examples. In §4, we propose a powerful method of identifying linearizing transformations. This method not only brings out all the known transformations systematically but also a new generalized linearizing transformation (GLT) for the third order ODEs. We emphasize the validity of the method with several illustrative examples arising in different areas of mathematics and physics. We present our conclusions in §5.

2. Prelle-Singer method for third order ODEs

(a) General Theory

Let us consider a class of third order ODEs of the form

\[ \ddot{x} = \frac{P}{Q}, \quad P, Q \in \mathbb{C}[t, x, \dot{x}, \ddot{x}], \quad (\dot{=}) \frac{d}{dt} \]  

where over dot denotes differentiation with respect to time and \( P \) and \( Q \) are polynomials in \( t, x, \dot{x}, \ddot{x} \) with coefficients in the field of complex numbers, \( \mathbb{C} \). Let us assume that the third order ODE (2.1) admits a first integral \( I(t, x, \dot{x}, \ddot{x}) = C \), with \( C \) being constant on the solutions, so that the total differential of \( I \) gives

\[ dI = I_t dt + I_x dx + I_{\dot{x}} d\dot{x} + I_{\ddot{x}} d\ddot{x} = 0, \]  

where each subscript denotes partial differentiation with respect to that variable. Equation (2.1) can be rewritten as \( \frac{P}{Q} dt - d\ddot{x} = 0 \). Now adding the null terms \( U(t, x, \dot{x}, \ddot{x})\dot{x}dt - U(t, x, \dot{x}, \ddot{x})d\dot{x} \) and \( S(t, x, \dot{x}, \ddot{x})\ddot{x}dt - S(t, x, \dot{x}, \ddot{x})dx \) to this we obtain that, on the solutions, the 1-form

\[ (\frac{P}{Q} + S\dot{x} + U\ddot{x})dt - Sdx - Ud\dot{x} - d\ddot{x} = 0. \]  

Article submitted to Royal Society
Looking at equations (2.2) and (2.3) one can conclude that, on the solutions, these two forms are proportional and the form of equation (2.3) is equivalent to equation (2.2) except for an overall multiplication factor. Thus multiplying equation (2.3) by the factor $R(t, x, \dot{x}, \ddot{x})$ which acts as the integrating factor for (2.3), we have on the solutions that

$$dI = R(\phi + S\dot{x} + U\ddot{x})dt - RSdx - RUd\dot{x} - Rd\ddot{x} = 0, \quad (2.4)$$

where $\phi \equiv P/Q$. Comparing equations (2.2) with (2.4) we have the following relations, on the solutions,

$$I_t = R(\phi + S\dot{x} + U\ddot{x}), \quad I_x = -RS, \quad I_{\dot{x}} = -RU, \quad I_{\ddot{x}} = -R. \quad (2.5)$$

Now imposing the compatibility conditions, $I_{tx} = I_{xt}, I_{t\dot{x}} = I_{\dot{x}t}, I_{t\ddot{x}} = I_{\ddot{x}t}, I_{xx} = I_{x\dot{x}}, I_{x\ddot{x}} = I_{\dot{x}x}, I_{\ddot{x}x},$ which exist between the equations (2.5), we have the following equations which constitute three determining equations ((2.6)-(2.8) given below) for the functions $S, U$ and $R$ along with three constraints ((2.9)-(2.11) given below) that they need to satisfy,

$$D[S] = -\phi_x + S\phi_{\ddot{x}} + US, \quad (2.6)$$

$$D[U] = -\phi_x + \phi_x - S + U^2, \quad (2.7)$$

$$D[R] = -R(U + \phi_{\ddot{x}}), \quad (2.8)$$

$$R_x = R_xS + RS_x, \quad (2.9)$$

$$R_xS = -RS_x + R_xU + RU_x, \quad (2.10)$$

$$R_\ddot{x} = R_\ddot{x}U + RU_{\ddot{x}}, \quad (2.11)$$

where

$$D = \frac{\partial}{\partial t} + \dot{x}\frac{\partial}{\partial x} + \ddot{x}\frac{\partial}{\partial \dot{x}} + \phi\frac{\partial}{\partial \ddot{x}}. \quad (2.12)$$

The task of solving equations (2.6)-(2.11) can be accomplished in the following way. Substituting the given expression of $\phi$ into (2.6)-(2.7) and solving them one can obtain expressions for $S$ and $U$. With the known $U$, equation (2.8) becomes the determining equation for the function $R$. Solving the latter one can get an explicit form for $R$. Compatible solutions to equations (2.6)-(2.8) can also be obtained in alternate ways, the details of which are given in §3.

Now the functions $R, U$ and $S$ have to satisfy an extra set of constraints, that is, equations (2.9)-(2.11). Suppose a compatible solution satisfying all the equations have been found then the functions $R, U$ and $S$ fix the differential invariant $I(t, x, \dot{x}, \ddot{x})$ by the relation

$$I(t, x, \dot{x}, \ddot{x}) = r_1 - r_2 - \int \left\{ RU + \frac{d}{dx} [r_1 - r_2] \right\} d\dot{x}$$

$$- \int \left\{ R + \frac{d}{dx} [r_1 - r_2] - \int \left\{ RU + \frac{d}{dx} [r_1 - r_2] \right\} d\dot{x} \right\} d\ddot{x}, \quad (2.13)$$

where

$$r_1 = \int R(\phi + S\dot{x} + U\ddot{x})dt, \quad r_2 = \int \left( RS + \frac{d}{dx} \int r_1 \right) dx.$$
Equation (2.13) can be derived straightforwardly by integrating the equations (2.5). Here it is to be noted that for every independent set $(S, U, R)$, equation (2.13) defines an integral.

(b) Exploring the complete form of $R$: Theory

From the above discussion, it is clear that equation (2.1) may be considered as completely integrable once we obtain three independent sets of the solutions $(S_i, U_i, R_i), \ i = 1, 2, 3,$ which provide three independent integrals of motion through the relation (2.13). Here we note that since we are solving equations (2.6)-(2.8) first and then check the compatibility of this solution with equations (2.9)-(2.11), one often meets the situation that all the solutions which satisfy equations (2.6)-(2.8) need not satisfy the constraints (2.9)-(2.11) since equations (2.6)-(2.11) constitute an overdetermined system for the unknowns $R, S$ and $U$. In fact for a class of problems one often gets one or two sets of $S, U, R$ which satisfy all the equations (2.6)-(2.11) and another set(s) $(S, U, R)$ which satisfies only the first three equations and not the other, namely, (2.9)-(2.11). In this situation we find an interesting fact that one can use the integral derived from the set(s) which satisfies all the six equations (2.6)-(2.11) and deduce the other compatible solution(s) $(S, U, R)$ (definition of $R$ follows). For example, let the set $(S_3, U_3, R_3)$ be a solution of the determining equations (2.6)-(2.8) and not of the constraints (2.9)-(2.11). After analysing several examples we find that one can make the set $(S_3, U_3, R_3)$ compatible by modifying the form of $R_3$ as

$$R_3 = F(t, x, \dot{x}, \ddot{x})R_3,$$

where $R_3$ satisfies equation (2.8), so that we have

$$(F_1 + \dot{x}F_x + \ddot{x}F_{\ddot{x}} + \phi F_{\dot{\phi}})R_3 + FD[R_3] = -FR_3(U_3 + \phi).$$

Further, if $F$ is a constant of motion (or a function of it), then the first term on the left hand side vanishes and one gets the same equation (2.8) for $R_3$ provided $F$ is non-zero. That is, whenever $F$ is a constant of motion or a function of it then the solution to (2.8) may provide only a factor of the complete solution $R_3$ without the factor $F$ in equations (2.14). This general form of $R_3$ along with $S_3$ and $U_3$ can now provide complete solution to equations (2.6)-(2.11) as discussed below.

(c) Exploring the complete form of $R$: Method

Now if the sets $(S_i, U_i, R_i), \ i = 1, 2,$ are found to satisfy the equations (2.6) - (2.11) and the third set $(S_3, U_3, R_3)$ does not satisfy equations (2.9) - (2.11) then $F$ may be a function of the integrals $I_i, \ i = 1, 2,$ derived from the sets $(S_i, U_i, R_i), \ i = 1, 2.$ We need to find the explicit form of $F(I_1, I_2)$ in order to obtain the compatible solution $(S_3, U_3, R_3).$ To do so let us find the derivatives of $R_3$ with respect to $x, \dot{x}$ and $\ddot{x}$:

$$\dot{R}_{3x} = (F_1 I_{1x} + F_2 I_{2x})R_3 + FR_{3x}, \quad \dot{R}_{3\dot{x}} = (F_1 I_{1\dot{x}} + F_2 I_{2\dot{x}})R_3 + FR_{3\dot{x}},$$
$$\dot{R}_{3\ddot{x}} = (F_1 I_{1\ddot{x}} + F_2 I_{2\ddot{x}})R_3 + FR_{3\ddot{x}},$$

(2.16)
where $F_1' = \frac{\partial F'}{\partial I_1}$ and $F_2' = \frac{\partial F'}{\partial I_2}$. Substituting equation (2.16) into equations (2.9)-(2.11), we have

$$\left(\frac{f_1F_1' + f_2F_2'}{f_3} \right) = \frac{F}{R_3}, \quad \left(\frac{f_4F_1' + f_5F_2'}{f_6} \right) = \frac{F}{R_3}, \quad \left(\frac{f_7F_1' + f_8F_2'}{f_9} \right) = \frac{F}{R_3},$$

(2.17a)

where

$$f_1 = (I_{1x} - I_{1z}S_3), \quad f_2 = (I_{2x} - I_{2z}S_3), \quad f_3 = (S_3R_{3x} + R_3S_{3x} - R_{3x})$$
$$f_4 = (I_{1z} - I_{1z}U_3), \quad f_5 = (I_{2z} - I_{2z}U_3), \quad f_6 = (U_3R_{3z} + R_3U_{3z} - R_{3z})$$
$$f_7 = (S_3I_{1z} - I_{1z}U_3), \quad f_8 = (S_3I_{2z} - I_{2z}U_3),$$
$$f_9 = (R_3U_{3z} + U_3R_{3z} - R_3S_{3z} - S_3R_{3z}).$$

(2.17b)

Equation (2.17a) represents an overdetermined system of equations for the unknown $F$. A simple way to solve this equation is to uncouple it for $F_1' = \frac{\partial F}{\partial I_1}$ and $F_2' = \frac{\partial F}{\partial I_2}$ and solve the resultant equations. For example, eliminating $F_2'$ from equation (2.17a) we obtain equations for $F_1'$ in the form

$$\frac{R_3F_1'}{F} = \frac{(f_3f_5 - f_2f_6)}{(f_1f_5 - f_2f_4)} = \frac{(f_3f_8 - f_2f_9)}{(f_1f_8 - f_2f_7)} = \frac{(f_6f_8 - f_5f_9)}{(f_4f_8 - f_5f_7)}.$$ 

(2.18)

On the other hand eliminating $F_1'$ from equation (2.17a) we arrive equations for $F_2'$ in the form

$$\frac{R_3F_2'}{F} = \frac{(f_3f_4 - f_1f_5)}{(f_2f_4 - f_1f_3)} = \frac{(f_3f_7 - f_1f_8)}{(f_2f_7 - f_1f_6)} = \frac{(f_6f_7 - f_4f_8)}{(f_5f_7 - f_4f_6)}.$$ 

(2.19)

It can be easily checked that the compatibility of the right three expressions in equations (2.18) or (2.19) give rise to relations which are effectively nothing but the constraint equations (2.9)-(2.11) and so no new constraint is added now. Consequently, equations (2.18) and (2.19) can be written as

$$\frac{\partial F}{\partial I_1} = g(I_1, I_2)F \quad \text{and} \quad \frac{\partial F}{\partial I_2} = h(I_1, I_2)F,$$

(2.20)

respectively, where $g(I_1, I_2) = \frac{1}{R_3} \frac{(f_3f_8 - f_2f_9)}{(f_1f_8 - f_2f_7)}$ and $h(I_1, I_2) = \frac{1}{R_3} \frac{(f_6f_8 - f_5f_9)}{(f_4f_8 - f_5f_7)}$. Now we can solve equations (2.20) and obtain the form of $F(I_1, I_2)$. This is demonstrated for several examples in the following sections explicitly. Once $F$ is known we can obtain the complete solution $R_3$ from which, along with $S_3$ and $U_3$, the third integral $I_3$ can be constructed. Thus with the explicit forms of the three integrals of motion, the complete integrability of equation (2.1) is guaranteed.

Finally, if the set $(S_1, U_1, R_1)$ alone is found to satisfy the equations (2.6) - (2.11) and the second set $(S_2, U_2, R_2)$ also does not satisfy equations (2.9) - (2.11), then $F$ may be a function of the integral $I_1$ alone which was derived from the set $(S_1, U_1, R_1)$. We need to find the explicit form of $F(I_1)$ in order to obtain the compatible solution $(S_2, U_2, R_2)$. To do so let us find the derivatives of $R_2$ with respect to $x$, $\dot{x}$ and $\ddot{x}$:

$$\dot{R}_{2x} = F_1' I_{1x} R_2 + F R_{2x}, \quad \dot{R}_{2\dot{x}} = F_1' I_{1x} R_2 + F R_{2\dot{x}}, \quad \dot{R}_{2\ddot{x}} = F_1' I_{1x} R_2 + F R_{2\ddot{x}},$$

(2.21)
where $F'_1 = \frac{\partial F}{\partial I_1}$. Substituting equation (2.21) into equations (2.9)-(2.11), we have

$$\frac{R_2 F'_1}{F} = \frac{s_2}{s_1} = \frac{s_4}{s_3} = \frac{s_6}{s_5},$$  \hspace{1cm} (2.22a)

where

$$s_1 = (I_{1x} - I_{1\ddot{x}} S_2), \quad s_2 = (S_2 R_{2\ddot{x}} + R_{2x}^2 S_{2x} - R_{2x}),$$

$$s_3 = (I_{1\ddot{x}} - I_{1x} U_2), \quad s_4 = (U_2 R_{2\ddot{x}} + R_{2x}^2 U_{2x} - R_{2x}),$$

$$s_5 = (S_2 I_{1\ddot{x}} - I_{1x} U_2), \quad s_6 = (R_2 U_{2x} + U_2 R_{2\ddot{x}} - R_{2x}^2 S_{2x} - S_2 R_{2x}).$$  \hspace{1cm} (2.22b)

One can again check that the compatibility of the right three expressions in equation (2.22a) leads to a condition, which is deducible from (2.9)-(2.11), and so no new condition is introduced in reality. Then rewriting equation (2.22a) as

$$\frac{\partial F}{\partial I_1} = \left( \frac{1}{R_2 s_1} \right) F = g(I_1)F,$$  \hspace{1cm} (2.23)

and solving it, one can obtain an explicit expression for $F$. Once $F$ is known we can construct the complete form of $\hat{R}_2$ from which, along with $S_2$ and $U_2$, the second integral of motion can be obtained. Once $I_1$ and $I_2$ are known, we can proceed to find the third compatible set $(S_3, U_3, \hat{R}_3)$ as before and obtain the third integral $I_3$ to establish complete integrability.

3. Methods of finding the explicit form of $R$

In §2 we outlined the method of solving the determining equations. However, in practice, it is difficult to solve equations (2.6)-(2.8) straightforwardly as they constitute a set of coupled first order nonlinear partial differential equations (PDEs). So one has to look for some intuitive ideas to solve these equations. We solve them and obtain the forms $R, U$ and $S$ in the following way. For this purpose, we observe the important fact that when we rewrite the coupled equations (2.6)-(2.8) into an equation for a single variable, namely, $R$, the resultant equation turns out to be a linear PDE. Then we solve this "$R$ equation" with a suitable ansatz (say polynomial or rational in $\ddot{x}$). Once 'R' is found the remaining functions $U$ and $S$ can be easily deduced.

As noted, rewriting equations (2.6)-(2.8) we arrive at a third order linear partial differential equation for $\hat{R}$ in the form

$$D^3[R] - D^2[\phi \dot{x}] + D[R \phi_x] - \phi_x R = 0, \quad D = \frac{\partial}{\partial t} + \dot{x} \frac{\partial}{\partial x} + \ddot{x} \frac{\partial}{\partial \ddot{x}} + \phi \frac{\partial}{\partial \phi}.$$

(3.1)

Solving equation (3.1) with a suitable ansatz in $\ddot{x}$ is relatively easier in many cases than solving equations (2.6)-(2.8). Once the explicit form of $R$ is obtained, $U$ can be deduced from equation (2.8) as

$$U = - \left( \frac{D[R]}{R} + \phi_x \right),$$

(3.2)

from which $S$ can be fixed by using equation (2.7). Now if this set $(S, U, R)$ forms a compatible set for the remaining equations (2.9)-(2.11) then the corresponding integral $I$ can be found using equation (2.13). To illustrate this idea let us look into the following examples.
Example: 1

Let us begin with a simple example, namely a linear third order ODE,

$$\ddot{x} + \lambda x = 0,$$  \hspace{1cm} (3.3)

where $\lambda$ is an arbitrary parameter. Substituting $\phi = -\lambda x$ into (3.1), we get the following equation for $R$

$$D^3[R] + \lambda R = 0, \quad D = \frac{\partial}{\partial t} + \dot{x} \frac{\partial}{\partial x} + \ddot{x} \frac{\partial}{\partial \dot{x}} - \lambda x \frac{\partial}{\partial \ddot{x}}.$$  \hspace{1cm} (3.4)

We now assume an ansatz for $R$ in the form

$$R = a(t, x, \dot{x}) + b(t, x, \dot{x}) \ddot{x},$$  \hspace{1cm} (3.5)

where $a$ and $b$ are arbitrary functions of $t, x$ and $\dot{x}$. Substituting (3.5) into (3.4) and equating the coefficients of different powers of $\ddot{x}$ to zero we get a set of linear partial differential equations for the variables $a$ and $b$. Solving them one obtains three nontrivial solutions,

$$R_1 = -e^{kt}, \quad R_2 = -(2\dot{x} + k\ddot{x} - k^2x)e^{-kt}, \quad R_3 = -\frac{\sqrt{3}k}{2}(\dot{x} + kx)e^{-kt},$$  \hspace{1cm} (3.6)

where $k^3 = \lambda$. Now substituting the form of $R_i$'s, $i = 1, 2, 3$, separately into the equation (3.2), we get

$$U_1 = -k, \quad U_2 = \frac{(2k^2\dot{x} + k\ddot{x} - k^2x)}{(2\dot{x} + k\ddot{x} - k^2x)}, \quad U_3 = \frac{(\ddot{x} - k^2x)}{(\dot{x} + kx)}.$$  \hspace{1cm} (3.7)

Now substituting the forms of $U_i$'s, $i = 1, 2, 3$, into (2.7) one can fix the forms of $S_i$'s, $i = 1, 2, 3$, as

$$S_1 = k^2, \quad S_2 = \frac{2k^4x + k^3\dot{x} - k^2\ddot{x}}{2\ddot{x} + k\ddot{x} - k^2x}, \quad S_3 = -\frac{k(\ddot{x} + k\dot{x})}{(\dot{x} + kx)}.$$  \hspace{1cm} (3.8)

As a consequence now we have three sets of independent solutions for the equation (2.6)-(2.8). Now we check the compatibility of these solutions with the remaining equations (2.9)-(2.11).

We find that the solutions $(S_1, U_1, R_1)$ and $(S_2, U_2, R_2)$ satisfy the equations (2.9) - (2.11), and become compatible solutions. Substituting the forms $(S_1, U_1, R_1)$ and $(S_2, U_2, R_2)$ separately into equation (2.13) and evaluating the integrals we get

$$I_1 = \frac{1}{3k^2} \left( \ddot{x} - k\dot{x} + k^2x \right) e^{kt},$$  \hspace{1cm} (3.9)

$$I_2 = \frac{2}{3k^2} \left( \dddot{x} + k^2\dddot{x} + k\dddot{x}x - k^2\dddot{x}\ddot{x} + k^3\dddot{x} \right) e^{-kt}.$$  \hspace{1cm} (3.10)

However, the set $(S_3, U_3, R_3)$ does not satisfy the extra constraints (2.9)-(2.11) which means that the form of $R_3$ may not be the 'complete form' but might be a factor of the complete form. As mentioned in §2, in order to recover the complete form $R_3$ one may assume that $R_3 = F(I_1, I_2)R_3$, where $F(I_1, I_2)$ is a function of $I_1$ and $I_2$.
the integrals $I_1$ and $I_2$. Now we have to determine the form of $F(I_1, I_2)$ explicitly and for this purpose we proceed as follows. Substituting
\[ \hat{R}_3 = F(I_1, I_2)R_3 = -\left[ \frac{\sqrt{3}k}{2}(\dot{x} + kx)e^{-kt} \right] F(I_1, I_2), \] (3.11)
into equations (2.18) and (2.19), along with (2.17b), we obtain two equations for $F$ as,
\[ F'_1 = 0, \quad I_2F'_2 + F = 0, \] (3.12)
where $F'_1$ and $F'_2$ denote partial derivatives of $F$ with respect to $I_1$ and $I_2$, respectively. Upon integrating (3.12) we get,
\[ F = \frac{1}{I_2}, \] (the integration constants are set to zero for simplicity) which fixes the form of $\hat{R}_3$ as
\[ \hat{R}_3 = \frac{R_3}{I_2} = -\frac{\sqrt{3}k}{2} \frac{(\dot{x} + kx)}{\left( \ddot{x}^2 + k^2 \dot{x}^2 + k_4x^2 + k_5 \ddot{x}x - k_6x^3 + k_7x \dot{x} \right)}. \] (3.13)

Now one can easily check that this set $(S_3, U_3, \hat{R}_3)$ is a compatible solution for the equations (2.6)-(2.11) which in turn provides $I_3$ through the relation (2.13) as
\[ I_3 = -\frac{\sqrt{3}k}{2} t + \tan^{-1} \left[ \frac{\ddot{x} - k \dot{x} - 2k^2 \dot{x}x}{\sqrt{3}(\dot{x} + k \ddot{x})} \right]. \] (3.14)

Using the explicit forms of the integrals $I_1$, $I_2$ and $I_3$, the solution to equation (3.3) can be deduced directly as
\[ x(t) = I_1 e^{-kt} + \sqrt{I_2} e^{kt} \cos \left( \frac{\sqrt{3}k}{2} t + I_3 \right). \] (3.15)

The result exactly coincides with the solution presented in Polyanin & Zaitsev (2000).

(ii) Example: 2

The applicability of this method to nonlinear ODEs can be illustrated by considering an equation of the form
\[ \dddot{x} = \frac{\ddot{x}^2}{\dot{x}} + \frac{\ddot{x} \dot{x}}{x}. \] (3.16)

Equation (3.16) is a sub-case of the general form of a scalar third order ODE which is invariant under the generators of time translation and rescaling (Feix et al. 1997; Polyanin & Zaitsev 2000). A sub-case of equation (3.16), namely, $\dddot{x} - c \ddot{x} = 0$, has been considered by both Bocharov et al. (1993) and Ibragimov & Meleshko (2005) to show that it can be linearized to a linear third order ODE through a contact transformation. On the other hand, Euler & Euler (2004) have considered the equation $\dddot{x} - \frac{\ddot{x}^3}{x} = 0$ and showed that it can be linearized through Sundman transformation (see §5c below). Here we consider the combined form (3.16) and derive integrating factors, integrals of motion and the general solution of this equation. Further, we show that the equation (3.16) itself can be linearized by the generalized linearizing transformation (GLT) (see §5d below).
As before, substituting $\phi = \frac{\ddot{x}}{x} + \frac{\dot{x}}{x}$ into (3.1), we get the following linear partial differential equation for $R$ as

$$D^3[R] - D^2\left(\frac{2\ddot{x}}{x} + \frac{\dot{x}}{x}\right)R - D\left(\frac{\dddot{x}^2}{x^2} - \frac{\ddot{x}}{x}\right)R + \frac{\dot{x}^2}{x}R = 0,$$

(3.17)

where $D$ is defined by equation (2.12). Now substituting the ansatz (3.5) into (3.17) and proceeding as before, we get

$$R_1 = -\frac{1}{\dot{x}}, \quad R_2 = \frac{x}{\dot{x}}, \quad R_3 = \frac{t\dot{x}^2 - x(\dot{x} + t\ddot{x})}{2x\ddot{x}^2},$$

(3.18)

Following the ideas given in Example 1, one can deduce the corresponding forms of $S_i$'s and $U_i$'s, $i = 1, 2, 3$, as

$$S_1 = -\frac{\ddot{x}}{x}, \quad U_1 = -\frac{\ddot{x}}{x},$$

$$S_2 = \frac{\ddot{x}}{x}, \quad U_2 = \frac{-2\dot{x}}{x} - \frac{\ddot{x}}{x},$$

(3.19)

$$S_3 = \frac{\dot{x}\ddot{x}(x + t\dot{x})}{x(-\ddot{x}^2 + x(\dot{x} + t\ddot{x}))}, \quad U_3 = \frac{\dot{x}\ddot{x}(2\dot{x} + t\ddot{x})}{\dot{x}(t\ddot{x}^2 - x(\dot{x} + t\ddot{x}))}.$$  

(3.20)

The solutions $(S_i, U_i, R_i)$, $i = 1, 2$, satisfy the constraints (2.9)-(2.11) so that they lead to first and second integrals of the form

$$I_1 = \frac{\ddot{x}}{\dot{x}x}, \quad I_2 = \frac{2x\ddot{x}^2 - x\ddot{x}}{\dot{x}}.$$  

(3.22)

In the present case also the set $(S_3, U_3, R_3)$ does not satisfy the extra constraints and so one has to explore the complete form of $\hat{R}_3$. To do so we proceed as before and obtain the forms of $F$ and $\hat{R}_3$ as $F = \sqrt{I_1I_2}$ and

$$\hat{R}_3 = \frac{t\dot{x}^2 - x(\dot{x} + t\ddot{x})}{2(\sqrt{I_1I_2})x\ddot{x}^2},$$

(3.23)

where the explicit forms of $I_1$ and $I_2$ are given in equation (3.22). Now one can check that the set $(S_3, U_3, \hat{R}_3)$ satisfies all the six equations (2.6)-(2.11) and furnishes the third integral $I_3$ through the relation (2.13) as

$$I_3 = -\frac{1}{2}(\sqrt{I_1I_2})t + \tan^{-1}\sqrt{\frac{I_1}{I_2}}x.$$  

(3.24)

Using the explicit forms of the integrals $I_1$, $I_2$ and $I_3$, the solution to equation (3.16) can be deduced directly as

$$x(t) = \sqrt{\frac{I_2}{I_1}}\tan\left[\frac{1}{2}(\sqrt{I_1I_2}t + 2I_3)\right].$$  

(3.25)

As can be seen from equation (3.23) the complete compatible solution $\hat{R}_3$ has $\ddot{x}$ term which appear inside the square root sign. This form of $\hat{R}_3$ can be explored only by making a suitable ansatz. Moreover one may also face more difficulties in solving the determining equations (2.6)-(2.8). In such complicated situations the complete solution $\hat{R}$ can be obtained by using our procedure.

*Article submitted to Royal Society*
(iii) Example:3

Let us consider a Chazy class of equation of the form (Halburd 1999; Mugan & Jrad 2002; Euler & Euler 2004)

\[ \ddot{x} + 4ax \dot{x} + 3a^2 x^2 + 6a^2 x^2 \dot{x} + a^3 x^4 = 0. \]  

(3.26)

Substituting \( \phi = -(4kx \dot{x} + 3k \dot{x}^2 + 6k^2 x^2 \dot{x} + k^3 x^4) \) into (3.1), we get

\[ D^3[R] + 4aD^2[xR] - 6aD[(\dot{x} + ax^2)R] + 4a(\ddot{x} + a^2 x^3 + 3ax \dot{x})R = 0. \]  

(3.27)

To solve the above equation we assume the same ansatz (3.5) for the variable \( R \). However, substituting this ansatz into equation (3.27) and solving the resultant equation we obtain only trivial solution. So we seek a rational form of ansatz for \( R \) in the form

\[ R = \frac{a(t, x, \dot{x}) + b(t, x, \dot{x}) \ddot{x}}{(c(t, x, \dot{x}) + d(t, x, \dot{x}) \ddot{x})^r}, \]  

(3.28)

where \( r \) is an arbitrary number. Substituting the equation (3.28) into equation (3.27) and solving the resultant partial differential equations we get

\[ R_1 = \frac{\dot{x} + ax^2}{(a^2 x^3 + 3ax \dot{x} + \ddot{x})^2}, \quad R_2 = \frac{t(-2x + ax^2 + t \dot{x})}{(a^2 x^3 + 3ax \dot{x} + \ddot{x})^2}, \]

\[ R_3 = \frac{t(3 - 3ax + a^2 t^2 x^2 + 2t \dot{x})}{(a^2 x^3 + 3ax \dot{x} + \ddot{x})^2}. \]  

(3.29)

The corresponding forms of \( S_i \)'s and \( U_i \)'s \( i = 1, 2, 3 \), are

\[ U_1 = \frac{2a^2 x^3 - \ddot{x}}{ax^2 + \ddot{x}}, \quad S_1 = \frac{\alpha(\alpha^2 x^4 + 3i \dot{x}^2 - 2i \ddot{x})}{a^2 x^3 + \ddot{x}}, \]

\[ U_2 = \frac{2x - 6a t x^2 + 2a^2 t^2 x^3 - t^2 \ddot{x}}{t(-2x + ax^2 + t \dot{x})}, \]

\[ S_2 = \frac{2a^2 x^2 - 4a^2 t x^3 + \alpha^3 t x^4 - 2i \ddot{x} + 3a^2 \dot{x}^3 + 2t \ddot{x}(1 - \alpha t x)}{t(3 - 3at x + a^2 t^2 x^2 + 2t \dot{x})}, \]

\[ U_3 = \frac{-3 - 12a t x + 9a^2 t^2 x^2 - 2a^3 t^3 x^3 + \alpha \dot{x}^3}{t(3 - 3at x + a^2 t^2 x^2 + 2t \dot{x})}, \]

\[ S_3 = \frac{(\alpha(12a t x^2 - 6a^2 t^2 x^3 + \alpha^3 t^3 x^4 + 3t(2i \dot{x} + at^2 x^2 + t \ddot{x}) - 2i(3 + \alpha t^3 x)))}{t(3 - 3at x + a^2 t^2 x^2 + 2t \dot{x})}. \]  

(3.30)

Now we proceed to find the integrals of motion. First we note that the functions \( (S_1, U_1, R_1) \) satisfy the constraints (2.9)-(2.11) and hence they are compatible. Thus substituting them into (2.13) the first integral \( I_1 \) is fixed easily as

\[ I_1 = -t + \frac{a^2 x^2 + \dot{x}}{a^2 x^3 + 3ax \dot{x} + \ddot{x}}. \]  

(3.31)

However, the set \( (S_2, U_2, R_2) \) (and so also \( (S_3, U_3, R_3) \)) does not satisfy the extra constraints (2.9)-(2.11) which means the form of \( R_2 \) may not be the ‘complete form’ but might be a factor of the complete form. As mentioned in §2, in order to recover
the complete form \( \hat{R}_2 \) one may assume that \( \hat{R}_2 = F(I_1)R_2 \). Here \( F(I_1) \) is a function of the integral \( I_1 \). Now we have to determine the form of \( F(I_1) \) explicitly and for this purpose we proceed as follows. Substituting

\[
\hat{R}_2 = F(I_1)R_2 = \frac{t(-2x + \alpha tx^2 + t\dot{x})}{(\alpha x^2 - \alpha^2 t x^3 + \dot{x} - 3\alpha t x \dot{x} - t \ddot{x})^2} F(I_1),
\]

(3.32)

into equation (2.22a), we obtain \( I_1 F'_1 + 2F = 0 \), where \( F'_1 \) denotes differentiation with respect to \( I_1 \). Upon integrating the latter we get \( F = I_1^{-2} \), (the integration constant is set to zero) which fixes the form of \( \hat{R}_2 \) as

\[
\hat{R}_2 = \frac{t(-2x + \alpha tx^2 + t\dot{x})}{(\alpha x^2 - \alpha^2 t x^3 + \dot{x} - 3\alpha t x \dot{x} - t \ddot{x})^2}.
\]

(3.33)

Now one can easily check that this set \((S_2, U_2, \hat{R}_2)\) is a compatible solution for the equations (2.6)-(2.11) which in turn provides \( I_2 \) through the relation (2.13) as

\[
I_2 = \frac{-2\alpha tx^2 + \alpha^2 t^2 x^3 + x(2 + 3\alpha t^2 \dot{x}) + t(-2\dot{x} + t \ddot{x})}{(\alpha x^2 - \alpha^2 t x^3 + \dot{x} - 3\alpha t x \dot{x} - t \ddot{x})}.
\]

(3.34)

As in the previous examples, the set \((S_3, U_3, R_3)\) does not satisfy the constraints (2.9)-(2.11) and hence one should seek a complete form for \( R_3 \), which we denote as \( \hat{R}_3 \), in the form

\[
\hat{R}_3 = F(I_1, I_2)R_3 = F(I_1, I_2) \frac{(3 - 3\alpha tx + \alpha^2 t^2 x^2 + \alpha^2 \dot{x})}{(\alpha x^2 - \alpha^2 t x^3 + \dot{x} - 3\alpha t x \dot{x} - t \ddot{x})^2}.
\]

(3.35)

Substituting (3.35) into equations (2.18) and (2.19), we obtain the following equations for \( F \), that is, \( I_1 F'_1 + 2F = 0 \), \( F'_2 = 0 \), where again \( F'_1 = \frac{\partial F}{\partial I_1} \) and \( F'_2 = \frac{\partial F}{\partial I_2} \). Upon integrating the equations we get the explicit form of \( F \) as \( F = \frac{1}{I_2} \), which in turn fixes the form of \( \hat{R}_3 \) as

\[
\hat{R}_3 = \frac{t(3 - 3\alpha tx + k^2 t^2 x^2 + \alpha^2 \dot{x})}{3\alpha(\alpha x^2 - \alpha^2 t x^3 + \dot{x} - 3\alpha t x \dot{x} - t \ddot{x})^2}.
\]

(3.36)

Now the set \((S_3, U_3, \hat{R}_3)\) satisfies all the six equations (2.6)-(2.11) and the relation (2.13) gives the form of third integral \( I_3 \) as

\[
I_3 = \frac{(6 + 3\alpha^2 t^2 x^2 - \alpha^3 tx^3 + 3\alpha^2 \dot{x} - 3\alpha tx(2 + \alpha^2 \dot{x}) - \alpha \dot{x}^3)}{6\alpha(\alpha x^2 - \alpha^2 t x^3 + \dot{x} - 3\alpha t x \dot{x} - t \ddot{x})}.
\]

(3.37)

Thus we have obtained the explicit forms of the integrals \( I_1 \), \( I_2 \) and \( I_3 \) and hence the solution to equation (3.3) is obtained directly as

\[
x(t) = \frac{\alpha \dot{x}^2}{\alpha^2 t^2} + I_1 t + I_1 I_2 \frac{\alpha \dot{x}^2}{\alpha^2 t^2} + I_1 I_2 \frac{\alpha \dot{x}^2}{\alpha^2 t^2} + I_1 t + I_1 I_3.
\]

(3.38)

Interestingly one can derive the solution (3.38) through an alternate way also. For example, instead of solving the 'R equation' with rational ansatz, one can look for equations in other variables, that is, either in \( U \) or in \( S \). For example, from equation (2.7) we get

\[
S = -(D[U] + \phi \dot{x} - U \dot{x}^2 - U^2).
\]

(3.39)
Substituting equation (3.39) into the equation (2.6) we get a nonlinear PDE for $U$:

$$D^2[U] - 3UD[U] - UD[\phi_x] + D[\phi_x] - \phi_x - \phi_x\phi_x + \phi_x^2 U$$

$$+ 2\phi_x U^2 - \phi_x U + U^3 = 0. \tag{3.40}$$

Now one can look for solutions of equation (3.40) with polynomial in $\ddot{x}$. Once $U$ is known one can make use of equations (3.39) and (2.8) to get the forms of corresponding $S$ and $R$ respectively. It turns out that for some cases, like the present example (3.26) (see the actual forms of $U$ in equation (3.30)), solving equation (3.40) is easier than solving equation (3.1) to solve. However, this can be decided only by actual calculation.

4. Linearization

In §2 and §3 we discussed the complete integrability of third order ODEs by investigating sufficient number of integrals of motion. However, one can also establish the complete integrability of the given nonlinear ODE by transforming it into a linear free particle second order ODE or into a third order linear ODE of the form $\frac{d^3w}{dx^3} = w''' = 0$. Unlike the second order ODEs, the third order nonlinear ODEs can be linearized through a wide class of transformations, namely, invertible point transformation (Steb 1993; Ibragimov & Meleshko 2005), contact transformation (Duarte et al. 1994; Bocharov et al. 1993; Ibragimov & Meleshko 2005), generalised Sundman transformation (Berkovich & Orlova 2000; Euler et al. 2003; Euler & Euler 2004) and their generalizations. In the following, we describe a procedure to deduce these transformations from the first integral itself and illustrate our ideas with relevant examples.

(a) Transformation from third order nonlinear ODEs to second order free particle equation

Let us suppose that the ODE (2.1) admits a first integral

$$I_1 = F(t, x, \dot{x}, \ddot{x}), \tag{4.1}$$

where $F$ is a function of $t, x, \dot{x}$ and $\ddot{x}$ only. Now extending our earlier proposal for second order ODEs (Chandrasekar et al. 2005) to the third order equations (2.1), let us split the function $F$ into a product of two functions such that one involves a perfect differentiable function $\frac{1}{G_2(t, x, \dot{x}, \ddot{x})} \frac{d}{dt}G_1(t, x, \dot{x})$ and another function $G_2(t, x, \dot{x}, \ddot{x})$, that is,

$$I_1 = F\left(\frac{1}{G_2(t, x, \dot{x}, \ddot{x})} \frac{d}{dt}G_1(t, x, \dot{x})\right). \tag{4.2}$$

Suppose $G_2$ is a total time derivative of another function, say, $z$, that is $\frac{dz}{dt} = G_2(t, x, \dot{x}, \ddot{x})$, then (4.2) can be further rewritten in the form

$$I_1 = F\left(\frac{1}{z} \frac{dG_1}{dt}\right) = F\left(\frac{dG_1}{dz}\right). \tag{4.3}$$
Now identifying the function $G_1(t, x, \dot{x}) = w$ as the new dependent variable, equation (4.3) can be recast in the form $I_1 = F(\frac{dw}{dz})$. In other words, we obtain
\[ \hat{I}_1 = \frac{dw}{dz}, \quad (4.4) \]
where $\hat{I}_1$ is a constant, from which one can get $\frac{d^2w}{dz^2} = 0$. Rewriting $w$ and $z$ in terms of old variables, namely,
\[ w = G_1(t, x, \dot{x}), \quad z = \int_o^t G_2(t', x, \dot{x}, \ddot{x})dt', \quad (4.5) \]
we can get a linearizing transformation to transform the third order nonlinear ODE into the second order free particle equation. Then to deduce the general solution one has to carry out one more integration.

(b) Transformation from third order nonlinear equation (2.1) to third order linear ODE $w''' = 0$

Next, we aim to transform equation (2.1) into a third order linear ODE and so we try to rewrite the first integral as a perfect second order derivative. We note that this can be done when one is able to evaluate the following integral explicitly,
\[ \hat{w} = \int_o^t G_1(t', x, \dot{x})G_2(t', x, \dot{x}, \ddot{x})dt' = G_3(t, x, \dot{x}), \quad (4.6) \]
where $G_1$ and $G_2$ are defined as in equation (4.2). Note that in the function $G_3$, the $\ddot{x}$ dependence has been integrated out. The reason for making such a specific decomposition is that in this case equation (4.2) can be rewritten as a simple second order ODE for the variable $\hat{w}$ (see equation (4.8) below). We pursued a similar kind of approach in the integrable force-free Duffing van der Pol oscillator equation (Chandrasekar et al. 2004) which has now been generalized in the present case. Here one can rewrite (4.1) as a perfect second order derivative as follows. Differentiating (4.6) with respect to $t$, we obtain $\frac{d\hat{w}}{dt} = G_1G_2$. Rewriting the left hand side in the form
\[ \frac{dz}{dt} \frac{d\hat{w}}{dz} = G_1G_2, \quad (4.7) \]
and using the identities already used in equation (4.5), namely $\frac{dz}{dt} = G_2$ and $G_1 = w$, in equation (4.7) the latter becomes
\[ \frac{d\hat{w}}{dz} = w. \quad (4.8) \]
Differentiating (4.8) with respect to $z$ and using the identity $\frac{dw}{dz} = \hat{I}_1$ (vide equation (4.4)), one gets $\frac{d^2\hat{w}}{dz^2} = \hat{I}_1$. In other words, we have
\[ \frac{d^3\hat{w}}{dz^3} = 0, \quad (4.9) \]
so that $\hat{w}$ and $z$ are the required transformation variables.

*Article submitted to Royal Society*
(c) The nature of transformations

In the previous two subsections, §4.1 and §4.2, we demonstrated how to construct linearizing transformations from the first integral and how they effectively change the given third order nonlinear ODE to either second or third order linear equation. Depending upon the explicit form of the transformations we can call them as point, contact, generalised Sundman or generalized linearizing transformations (GLT). To demonstrate how different kinds of transformation arise let us consider the transformation, \( \hat{w} = G_3, \quad z = \int_0^t G_2 dt' \) (vide equations (4.6) and (4.5)), which takes the given nonlinear ODE into a linear equation. Now, in the above transformation, suppose \( z \) is a perfect differentiable function and \( \hat{w} \) and \( z \) do not contain the variable \( \dot{x} \) and \( \ddot{x} \), then we call the resultant transformation, namely, \( \hat{w} = f_1(x, t) \) and \( z = f_2(x, t) \), as a point transformation. Further, if the transformation admits the variable \( \dot{x} \) also explicitly then it becomes the contact transformation. In this case, we have \( w = f_1(t, x, \dot{x}) \) and \( z = \int_0^t G_2(t', x) dt' \) then the transformation is said to be a generalised Sundman transformation. Note that in the latter case the new independent variable is in an integral form. Besides the above, as pointed out earlier, we find that there exists another kind of transformation, namely, generalized linearizing transformations (GLT), in which the new dependent and independent variables take the form \( \hat{w} = G_3(t, x, \dot{x}) \) and \( z = \int_0^t G_2(t', x, \dot{x}, \ddot{x}) dt' \), respectively.

(d) Connection between the functions \( G_1, G_2 \) and \( G_3 \)

Finally we explore the connection between the functions \( G_1, G_2 \) and \( G_3 \). As we have seen above, for the given equation to be linearizable it should be transformable to the form (4.8). Rewriting the latter in terms of the variables, \( G_1, G_2 \) and \( G_3 \) we get,

\[
G_3 \dot{t} + \dot{x}G_3x + \ddot{x}G_3 \dot{x} = G_1(t, x, \dot{x})G_2(t, x, \dot{x}, \ddot{x}).
\]  

(4.10)

Note that the left hand side of equation (4.10) contains the variable \( \ddot{x} \) linearly. So the right hand side should also be linear in \( \ddot{x} \). Consequently, we can write

\[
G_2(t, x, \dot{x}, \ddot{x}) = G_{21}(t, x, \dot{x})\ddot{x} + G_{22}(t, x, \dot{x}).
\]  

(4.11)

Using (4.11) we can rewrite equation (4.10) in the form

\[
\left( \frac{G_3 \dot{t} + \dot{x}G_3x}{G_{22}} \right) \left( 1 + \frac{\ddot{x}G_{3x}}{G_{3t} + \dot{x}G_{3x}} \right) = G_1.
\]  

(4.12)

Since the right hand side is independent of \( \ddot{x} \), we have from (4.12) that

\[
G_{21}(G_3 \dot{t} + \dot{x}G_3x) = G_{22} G_{3x} \quad \text{and} \quad G_1 = \frac{G_{3x}}{G_{21}}.
\]  

(4.13)

It may be noted that a similar condition has been derived by Bocharov et al. (1993) and Ibragimov & Meleshko (2005) for the case \( G_2 \) is a perfect differential
function. In other words, our procedure indicates that more generalized transformations are possible in the case of third order ODEs. By imposing the condition (4.11) it becomes clear that whatever be the type of linearizing transformation, the new independent variable should be at the maximum linear in $\ddot{x}$.

(e) Transformation to fourth and higher order linear ODEs

In the above sub-sections §4a, §4b, §4c and §4d we can concentrated only on transforming a nonlinear third order ODE either to a second order or third order linear equations only. However, one could also linearize certain third order nonlinear ODEs to fourth order linear ODE. For example the equation (3.26) is linearizable to a fourth order ODE of the form $d^4w/dz^4 = 0$, under the nonlocal transformation $x = \frac{\dot{w}}{\alpha w}$. This is not an isolated example and one can linearize a class equations through this procedure. Besides the above one can also consider linearizing transformations in which the new dependent variable, $\hat{w}$, is a non-local one. This choice leads us to classify another a large class of equations which we leave it for future work.

5. Application

In this section we consider specific examples to demonstrate the method given in §4.

(a) Example 1: Point transformation

Let us consider a nontrivial example which was discussed by Steeb (1993) in the context of invertible point transformations, namely,

$$\ddot{x} + \frac{3\dot{x}\ddot{x}}{x} - 3\dot{x} - \frac{3\dot{x}^2}{x} + 2\dot{x} = 0. \tag{5.1}$$

The first integral, which can be obtained using the formulation in §2, can be written as

$$I_1 = \left(\dot{x}^2 + x\ddot{x} - x\dot{x}\right)e^{-2t}. \tag{5.2}$$

Rewriting (5.2) in the form (4.2) we get $I_1 = e^{-t} \frac{d}{dt}(x\dot{x}e^{-t})$, so that

$$w = x\dot{x}e^{-t}, \quad z = e^t. \tag{5.3}$$

As we noted earlier, one could transform (5.1) to the second order free particle equation, $\frac{d^2w}{dz^2} = 0$, by utilizing the transformation (5.3). Integrating the equation $\frac{d^2w}{dz^2} = 0$ we get $w = I_1z + I_2$. Using (5.3) into this expression, the general solution of equation (5.1) can be obtained (after an integration) as

$$x(t) = (I_1 e^{2t} + I_2 e^t + I_3)^{\frac{1}{2}}, \tag{5.4}$$

where $I_i$, $i = 1, 2, 3$, are the integration constants.

Further, using the equation (4.6) we get $\dot{w} = \int x\dot{x}dt = \frac{x^2}{2}$. Then we can directly check that the point transformation

$$\hat{w} = \frac{x^2}{2}, \quad z = e^t, \tag{5.5}$$

\textit{Article submitted to Royal Society}
Integrability and Linearization

transforms the equation (5.1) to the form $\frac{d^3 \hat{w}}{dz^3} = 0$. As we mentioned earlier, since $\hat{w}$ and $z$ involve only $x$ and $t$ they are just point transformations. Integrating the linear equation $\frac{d^3 \hat{w}}{dz^3} = 0$ we get

$$\hat{w} = \frac{I_1}{2}z^2 + I_2z + I_3.$$  

(5.6)

Rewriting $\hat{w}$ and $z$ in equation (5.6) in terms of the original variables $x$ and $t$ by using the transformation (5.5) we get the same solution as equation (5.4).

(b) Example 2: Contact transformation

Let us consider an equation of the form

$$\dddot{x} = \frac{x}{x^2},$$  

(5.7)

Bocharov et al. (1993) have shown that equation (5.7) can be linearized through contact transformation. However, the explicit linearizing transformation is yet to be reported which is also a difficult problem. Here we derive the explicit form of the linearizing transformation through our procedure.

The first integral can be easily deduced using the results of §2 as

$$I_1 = \frac{\dot{x}^2 - x\ddot{x}}{\ddot{x}}.$$  

(5.8)

Rewriting (5.8) in the form (4.2) we get $I_1 = \frac{\dot{x}}{\ddot{x}} \frac{d}{dt}(\frac{x}{\dot{x}})$ so that we have $w = \frac{x}{\dot{x}}$ and $z = \log \dot{x}$. The latter transforms equation (5.7) to the second order free particle equation $\frac{d^2 w}{dz^2} = 0$, so that $w = I_1z + I_2$, where $I_1$ and $I_2$ are integration constants. Rewriting $w$ and $z$ in terms of the old variables we get $x = (I_1 \log(\dot{x}) + I_2)\dot{x}$. Unlike the earlier example it is difficult to integrate this equation further and obtain the general solution. Therefore one can look for variables which transform the third order nonlinear ODE (5.7) to a third order linear ODE so that the non-trivial integration can be avoided. Now using the equation (4.6) we get $\hat{w} = \int \frac{\dot{x}^2}{\ddot{x}} dt = t - \frac{\dot{x}}{\ddot{x}}$. The new variables

$$\hat{w} = \frac{t\dddot{x} - x}{\ddot{x}}, \quad z = \log \dot{x},$$  

(5.9)

transform the equation (5.7) to the form (4.9). Unlike the earlier example, $\hat{w}$ and $z$ admit the variable $\dot{x}$ explicitly and so they become contact transformation for the given equation.

Integrating the linear third order equation (4.9), we get $\hat{w} = \frac{I_1}{2}z^2 + I_2z + I_3$, where $I_i$, $i = 1, 2, 3$, are integration constants. Now replacing $\hat{w}$ and $z$ in terms of the old variables and using the previous result $x = (I_1 \log(\dot{x}) + I_2)\dot{x}$, one can obtain the general solution for the equation (5.7) in the form

$$x(t) = \left(- I_1 \pm \sqrt{I_1^2 + I_2^2 - 2I_1(I_3 - t)} \right) e^{-\frac{I_1 + I_2 + \sqrt{I_1^2 + I_2^2 - 2I_1(I_3 - t)}}{I_1}}.$$  

(5.10)
Example 3: Generalised Sundman transformation

Next we consider the hydrodynamic type equation of the form (Berkovich & Orlova 2000; Euler & Euler 2004)
\[
\dddot{x} = \frac{\ddot{x}\dot{x}}{x},
\]  
(5.11)

which admits a first integral in the form \(I_1 = \dot{x}\) and the latter can be rewritten as \(I_1 = \frac{1}{x}\frac{d}{dx}\dot{x} = \frac{dw}{dz}\), from which we identify \(w = \dot{x}\) and \(dz = xdt\). By utilizing the new variables, one can transform (5.11) to the second order free particle equation, \(\frac{d^2w}{dz^2} = 0\). However, from equation (4.6) we get \(\hat{w} = \int x\dot{x}dt = x^2\). Then the Sundman transformation
\[
\hat{w} = x^2, \quad dz = xdt,
\]  
(5.12)

transforms the equation (5.11) to the form (4.9), namely \(\frac{d^3}{dz^3}\hat{w} = 0\).

To derive the solution we proceed as follows. Rewriting the first integral \(I_1\) in the integral form we get, \(I_1 = \frac{1}{x}\frac{d}{dx}\dot{x} \Rightarrow \dot{x} = I_1 \int xdt\). Now using the identity (5.12) in the latter expression we get \(w = I_1z\). From equation (4.6) (for the present case \(G_1 = w\) and \(G_2 = \frac{d}{dt}\)) we have
\[
\hat{w} = \int wdz = \int I_1zdz = \frac{I_1}{2}z^2 + I_2,
\]  
(5.13)

where \(I_2\) is the integration constant. Using (5.12) in (5.13) we obtain \(x^2 = \frac{I_1}{2}z^2 + I_2\), which in turn leads to a differential equation which connects the variables \(z\) and \(t\) in the form (using the relation \(dz = xdt\))
\[
dz = \sqrt{\frac{I_1}{2}z^2 + I_2}dt.
\]  
(5.14)

Integrating (5.14), we obtain \(z = \sqrt{I_2\left(e^{\sqrt{I_1}(t+I_3)} - e^{-\sqrt{I_1}(t+I_3)}\right)}\), where \(I_3\) is the integration constant. Substituting the latter in the relation \(x^2 = \frac{I_1}{2}z^2 + I_2\), we arrive at the general solution for (5.11) in the form
\[
x(t) = \sqrt{I_2} \cosh \sqrt{I_1}(t + I_3).
\]  
(5.15)

We note that the solution for the equation (5.11) has been already derived in an alternate way from the Sundman transformation (5.12) by Euler & Euler (2004). However the procedure which we described in the above is new and can be used for more general linearizing transformations also, as we see below.

Example 4: Generalized linearizing transformation (GLT)

As we noted earlier some nonlinear ODEs can be linearized only through more general nonlocal form of transformations, which we designate here as generalized linearizing transformations (GLTs). We illustrate the GLT with the same example discussed as Example 2 in §3, which admits a first integral of the form \(I_1 = \frac{\dot{x}}{x}\) (vide
Integrability and Linearization

Equation (3.16). Rewriting this first integral in the form (4.2) we get $I_1 = \frac{\ddot{x}}{x} dt(x)$, so that

$$w = x, \quad dz = \frac{\ddot{x}}{x} dt,$$

which can be effectively used to transform the nonlinear ODE (3.16) to the equation $\frac{d^2 w}{dz^2} = 0$. Using the equation (4.6) we get $\dot{w} = \int \ddot{x} dt = \dot{x}$. Then the GLT becomes

$$\dot{w} = \dot{x}, \quad dz = \frac{\ddot{x}}{x} dt,$$

which can be used to transform the equation (3.16) to the form $\dot{w}'' = 0$. Note that in the present case the new independent and dependent variables admit $\ddot{x}$ and $\dot{x}$ terms, respectively and that the transformation is nonlocal. Indeed no such linearizing transformations have been reported in the literature at least to our knowledge. We also now establish a method of finding the general solution for this case.

Integrating once the equation $\frac{d^2 w}{dz^2} = 0$ we get $w = I_1 z$ from which we obtain

$$x = I_1 z.$$

On the other hand equation (4.6) provides us a relation (after using (5.16) and (5.17))

$$\dot{x} = \frac{I_1}{2} z^2 + I_2.$$

Now using (5.18) in (5.19), we obtain

$$\left(\frac{2I_1}{I_1 z^2 + 2I_2}\right) dz = dt.$$

The variables are now separated out and one can integrate (5.20) and obtain

$$z = \frac{2I_2}{I_1} \tan \left(\frac{I_2}{I_1}(t + I_3)\right).$$

Now substituting (5.21) into (5.18) we get

$$x(t) = \sqrt{2I_1 I_2} \tan \left(\frac{I_2}{I_1}(t + I_3)\right).$$

which is effectively the same as (3.25).

Finally, we note that the procedure given above can be profitably utilized for other examples also which are linearized by GLTs.

(e) Example 5: An elementary nontrivial system of hydrodynamic type

Finally, to show the importance of the GLT and how this transformation gives additional information about the linearization of nonlinear third order ODEs we consider the following specific example which was discussed in the literature (Berkovich 1996; Berkovich & Orlova 2000),

$$\ddot{x} = \frac{\dddot{x}}{x} - 4\alpha x^2 \ddot{x}, \quad \alpha: \text{parameter.}$$

Article submitted to Royal Society
Equation (5.23) is nothing but the dynamical equation of the Euler-Poinsot case of a rigid body written in terms of a single variable (Berkovich 1996; Berkovich & Orlova 2000). As we have seen earlier this equation is linearizable in the case $\alpha = 0$ through generalized Sundmann transformation. However, we wish to show here that the general equation (5.23) itself is linearizable through the GLT.

From the first integral $I_1 = \frac{x}{2} + 2\alpha x^2$ associated with equation (5.23), one can identify the GLT

$$\dot{w} = x^2, \quad dz = \frac{2\dot{x}}{\sqrt{x^2 + \alpha x^4}} dt,$$

which transforms the equation (5.23) to the form (4.9). Note that for the choice $\alpha = 0$ the independent variable becomes $dz = 2xdt$ and so it becomes the generalized Sundman transformation, equation (5.12), identified in the literature (Berkovich & Orlova 2000; Euler & Euler 2004). Now following the steps given in Example 4 one can deduce the general solution for the equation (5.23) in terms of Jacobian elliptic function as

$$x(t) = \left( I_1(c - (c - b)\sqrt{\alpha I_1(c-a)}(t-t_0), m)] + I_2 \right)^{\frac{1}{2}},$$

where $a + b + c = \frac{(2I_2-3\alpha I_1)}{4\alpha I_1}$, $ab + ac + cb = \frac{(3\alpha I_2-2I_1 I_2)}{4\alpha I_1^2}$, $abc = -\frac{I_2^2}{4I_1^2}$, $m^2 = \frac{b-c}{a-c}$ and $I_2$ and $t_0$ are integration constants.

6. Conclusion

In this paper we have discussed a method of finding the integrals of motion and general solution associated with third order nonlinear ODEs through the modified PS method by a nontrivial extension of our earlier work on second order ODEs (Chandrasekar et al. 2005). We illustrated the validity of the method with suitable examples. Further, we introduced a technique which can be utilized to derive linearizing transformations from the first integral. Interestingly, we showed that different types of transformations, namely, point, contact, Sundman and generalized linearizing transformations can be derived in a unique way from the first integral. We also indicated a procedure to derive general solution for the third order ODEs when GLTs occur. We believe that the GLT introduced in this paper will be highly useful to tackle new systems such as equation (5.23). Finally, the modified PS method can also be extended to higher order ODEs and coupled systems of ODEs. As far as the linearization of higher order ODEs are concerned it is still an open and challenging problem. As we pointed out in the introduction one can unearth a wide variety of linearizing transformations for the higher order ODEs besides formulating the necessary and sufficient condition for linearizing these equations in each form of transformation. We hope to address some of these aspects shortly.

The work of VKC is supported by Council of Scientific and Industrial Research in the form of a Senior Research Fellowship. The work of MS and ML forms part of a Department of Science and Technology, Government of India, sponsored research project.
