Abstract Objective: To analyze prescription pattern of antihypertensive drugs in patients with hypertension alone and with coexisting diseases. Methodology: A descriptive cross-sectional study was conducted in outpatient department of tertiary care hospital in south India. A total of 286 prescriptions of patients diagnosed to have hypertension with or without coexisting diseases were collected. Details of prescriptions were entered in the preformed pro forma and analyzed. Result: The study included 138 (48.25%) male and 148 (51.75%) female. Out of 286 hypertensives, 122 (42.66%) patients were having co-existing type 2 diabetes mellitus (T2DM). And remaining 164 patients (57.34%) were only hypertensives. Out of 286 patients, 227 (79.31%) patients were on monotherapy, 49 (17.13%) were on dual therapy and remaining 10 patients were on triple anti-hypertensive drugs. Among 150 antihypertensive drugs that are prescribed for hypertensive patients with T2DM, 57 (38%) were calcium channel blocker (CCB), 40 (26.66%) were angiotensin converting enzyme inhibitors (ACEI), 31 (20.66%) were angiotensin receptor blockers (ARB), 13 (8.66%) were diuretics and remaining 9 (6%) were beta blockers. Similarly, among 206 antihypertensive drugs prescribed for hypertension alone patients, 97 (47%) were CCB, 37 (17.96%) were ACEI, 31 (15%) were ARB, 26 (12.62%) were diuretics and remaining 15 (7.28%) were beta blockers. Conclusion: The study has shown that majority of patients were on monotherapy (79.31%) and calcium channel blockers were commonly prescribed for hypertension in patients with or without type 2 diabetes mellitus followed by ACE inhibitors, ARB and beta blockers.

Keywords Antihypertensive Drugs, Prescription Pattern Analysis, Cross Sectional Study

1. Introduction

Hypertension (HTN) is the commonest chronic medical condition responsible for coronary artery disease, stroke, chronic kidney disease and peripheral vascular diseases. Nearly 26% of adult population suffering from hypertension in worldwide. About 33% of urban and 25% of rural population affected by hypertension in India. According to World Health Organization, hypertension is one of the important causes for premature death in worldwide.

The definition of hypertension as released by the seventh report of the Joint National Committee on Prevention, Detection, Evaluation and Treatment of High Blood Pressure (JNC 7) is systolic blood pressure (SBP) ≥ 140 mmHg or diastolic blood pressure (DBP) ≥ 90 mm Hg, which simplifies hypertension classification by including only stage I (SBP 140-159 mm Hg or DBP 90-99) or stage II (SBP 160 mm Hg or higher or DBP 100 mm Hg or higher). Perhaps the most important change is the new classification of “pre-hypertension” (SBP 120-139 mm Hg or DBP 80-89 mm Hg), which combines the normal and high normal categories of the previous JNC VI report, in the recognition of the fact that even these levels of BP confer an increased risk of the development of hypertension and future cardiovascular events. HTN is usually asymptomatic and its diagnosis is mainly through screening, or when a person is seeking healthcare for an unrelated problem. Some proportion of hypertensive report headaches (particularly in the morning hours at the back of the head and), as well as lightheadedness, vertigo, tinnitus, altered vision or fainting episodes.

The primary goal of management of HTN is to prevent morbidity and mortality associated with it. Majority of hypertensive patients require two or more antihypertensive medications. Thiazide diuretics, β-blockers, angiotensin converting enzyme inhibitors (ACEIs), angiotensin receptor blockers (ARB) and calcium channel blockers (CCB) all have been shown to reduce complications of hypertension and can be used for initial management of HTN.

Availability of numerous antihypertensive drugs gives treating physician several options to individualize the therapy. Due to this reason there can be change in the prescribing pattern from patient to patient and physician to physician. General principles of antihypertensive therapy conforming to the guidelines of JNC VII and WHO & International Society of Hypertension (ISH) are considered.
Rational drug prescribing is defined as the use of the least number of drugs to obtain the best possible effect in the shortest period and at a reasonable cost. Measurement of drug usage pattern in healthcare not only describes the behavior of prescribers but also the extent of polypharmacy and the problems associated with it.

2. Objectives

To analyze prescription patterns of antihypertensive drugs in patients with hypertension alone and with coexisting diseases.

3. Materials and Methods

This descriptive cross-sectional study was conducted in the outpatient department of General Medicine, Yenepoya Medical College, Mangalore from January 2017 to March 2017. Ethical approval was obtained from Institutional Ethics Committee before starting the study. Sample size was calculated based on the average number of hypertensive patients visiting the General Medicine outpatient department of Yenepoya Medical College Hospital per day. During the period of 3 months, a total of 286 prescriptions (calculated sample size was 250) of patients diagnosed to have hypertension with or without coexisting diseases were collected. Informed consent was obtained from the participants. Details of prescriptions of the patients were entered in the preformed pro forma and analyzed.

3.1. Inclusion Criteria

Known hypertensive patients (with or without coexisting diseases) of either sex aged between 25-90 years of age.

3.2. Analysis

Data will be analyzed and results are expressed in percentages.

4. Results

A total of 286 prescriptions were collected from the hypertensive patients attending the outpatient department of General Medicine. The study included 138 (48.25%) male and 148 (51.75%) female individuals (Table 1). The age range was from 25 to 86 years old. Total number of antihypertensive drugs was found to be 356 for 286 patients and average number of drugs per prescription was 1.24 in this present study.

| Gender   | Number | Percentage | Age range   |
|----------|--------|------------|-------------|
| Male     | 138    | 48.25      | 30-83 Years |
| Female   | 148    | 51.75      | 25-86 Years |
| Total    | 286    | 100        |             |

Out of 286 hypertensive patients, 122 (42.66%) patients were also suffering type 2 diabetes mellitus. And remaining 164 patients (57.34%) were receiving only anti-hypertensive medications (Table 2).

| Disease                      | Number | Percentage |
|------------------------------|--------|------------|
| Hypertension alone           | 164    | 57.34      |
| Hypertension with diabetes   | 122    | 42.66      |
| Total                        | 286    | 100        |

Table 3 shows prescription details of hypertensive patients without co-existing diabetes mellitus. Out of 164 hypertensive alone patients, 125 patients (76.21%) were on monotherapy, 31 patients were on dual therapy and remaining 8 patients were on triple antihypertensive therapy.

| Prescription type | Number | Percentage |
|-------------------|--------|------------|
| Mono-therapy      | 125    | 79.21      |
| Dual-therapy      | 31     | 18.91      |
| Triple therapy    | 8      | 4.88       |
| Total             | 164    | 100        |

Similarly, Table 4 shows prescription details of hypertensive patients with co-existing diabetes mellitus patients. Out of 286 hypertensive patients, around 227 (79.31%) patients were on single drug for hypertension. And 49 (17.13%) individuals were prescribed dual antihypertensive agents. Whereas, remaining 10 patients were on triple anti-hypertensive medications.

| Prescription type | Number | Percentage |
|-------------------|--------|------------|
| Mono-therapy      | 227    | 79.31      |
| Dual-therapy      | 49     | 17.13      |
| Triple therapy    | 10     | 3.46       |
| Total             | 286    | 100        |

A total of 150 antihypertensive drugs were prescribed for 122 hypertensive patients with co-existing type 2 diabetes mellitus. Among 150 antihypertensive drugs, 57 (38%) were calcium channel blocker (CCB), 40 (26.66%) were angiotensin converting enzyme inhibitors (ACEI), 31 (20.66%) were angiotensin receptor blockers (ARB), 13 (8.66%) were diuretics and remaining 9 (6%) were beta blockers.
blocker for the management of hypertension (Table 5).

Table 5. Table showing the details of antihypertensive agents in hypertensive patients with co-existing type 2 diabetes mellitus.

| Group                  | Number | Percentage |
|------------------------|--------|------------|
| Calcium channel blockers | 57     | 38         |
| ACEI                   | 40     | 26.66      |
| ARB                    | 31     | 20.66      |
| Diuretics              | 13     | 8.66       |
| Beta blockers          | 09     | 6          |
| **Total**              | **150**| **100**    |

Similarly, a total of 206 antihypertensive drugs were prescribed for 164 hypertensive patients without any co-existing diseases. Among 206 antihypertensive drugs, 97 (47%) were calcium channel blocker (CCB), 37 (17.96%) were angiotensin converting enzyme inhibitors (ACEI), 31 (15%) were angiotensin receptor blockers (ARB), 26 (12.62%) were diuretics and remaining 15 (7.28%) were beta blocker for the management of hypertension (Table 6).

Table 6. Table showing the details of antihypertensive agents in hypertension alone patients

| Group                  | Number | Percentage |
|------------------------|--------|------------|
| Calcium channel blockers | 97     | 47         |
| ACEI                   | 37     | 17.96      |
| ARB                    | 31     | 15         |
| Diuretics              | 26     | 12.62      |
| Beta blockers          | 15     | 7.28       |
| **Total**              | **206**| **100**    |

5. Discussion

A prescription based on study is considered to be one of the most effective methods to assess and evaluate drug utilization of medication. Prescription by the clinician may be taken as a reflection of his/her attitude towards the disease and role of the drug in treatment. It also provides insight on the nature of healthcare delivery system. The objectives of antihypertensive treatment are to control hypertension and also to reduce mortality and morbidity associated with hypertension. Most of the hypertensive individuals require two or more drugs for the proper control of blood pressure. Sometimes presence of co-existing disease affects the selection of antihypertensive drugs. [10]

The United States Joint National Committee on the prevention, detection, evaluation and treatment of high blood pressure states that in the absence of compelling or specific indications for another drug, a diuretic or β-blocker should be chosen as initial therapy for hypertension [11]. These recommendations were seconded by the British Hypertension Society [12].

Use of multiple drugs in combinations has become routine to control hypertension in patients with diabetes. Several studies have demonstrated that most patients with hypertension could achieve and sustain adequate blood pressure control only with the use of multiple antihypertensive drugs [13]. However, in our study majority of the patients in our study were on monotherapy (79.31%) followed by dual-therapy (17.13%) and triple therapy (3.46%). Present study has shown that round 42.66% of hypertensives have co-existing type 2 diabetes mellitus. These findings are similar to the previous studies done in India.[14] Several studies in India have shown an increasing trend in the prevalence of HTN among urban adults. HTN is responsible for 57% of all stroke mortality and 24% of all CAD mortality in India. [15] HTN substantially increases the risk of both macrovascular and microvascular complications in DM.

In our study, calcium channel blockers are most commonly used antihypertensive agents both in hypertension alone (47%) and with coexisting type 2 diabetes mellitus patients (38%). ACE inhibitors and ARB agents are preferred next to calcium channel blockers. These findings coincides with the study done by Pang-Hsiang Lui et al. [16] Beta blockers and diuretics are less commonly used antihypertensive agents in our study.

6. Conclusions

Present study interprets the current prescribing pattern of antihypertensive agents at our study site. CCB are the leading group of antihypertensive agents followed by ACEI, ARB, Beta blockers and diuretics.
